The location of the windmill on the hill, and the watermill by the stream, indicates how conditions of human labour have been determined by the need of mechanical energy. The earlier cotton mills were all placed where water power was available, although this had the disadvantage of taking them away from the places where skilled workmen were found, and from the markets for manufactured goods. In an interesting pamphlet on "The Rise of the Cotton Trade," by John Kennedy, of Ardwick Hall, written in 1815, it is stated that for some time after Arkwright's first mill was erected at Cromford all the principal mills were built near river falls, no other power than water power having been found practically useful. After the invention of the steam engine, manufacturing industries gathered round the coalfields. "About 1790," says Mr. Kennedy, "Mr. Watts's steam engine began to be understood, and waterfalls became of less value. Instead of carrying the people to the power, it was found preferable to place the power amongst the people." The tendency of the conditions created by the introduction of steam power has been to concentrate the industrial population into large communities, and to confine manufacturing operations to large factories. Economy in the production of power, economy of superintendence, and the costliness of the machinery employed, all favoured the growth of the factory system. Facilities for distributing power are of much more modern origin, and they may partially reverse the tendency to concentration, and enable small workshops and household industries to regain a commercially satisfactory position. Further, to whatever extent facility for conveying power permits the utilisation of new sources of energy, there may be a displacement of industries to new localities. The mountain districts, with abundant water power, may have an advantage over districts where coal is obtained.

Sources of Mechanical Energy.

In these lectures motive power is treated as a commodity, producible, distributable, saleable. The first question is as to the sources from which it can be obtained.

Wind power has been used for driving ships and mills, and now and then it is alleged that, as a source of power, wind action has been too much neglected. But its intermittence restricts its use to work which can be intermittent also. The comparatively short periods in which the wind pressure is a considerable force make it uneconomical to attempt to do more than to utilise very moderate winds. On the other hand, the occasional great intensity of wind action during short periods involves the necessity that structures exposed to its action should be of excessive strength and costliness.

Tidal action might, no doubt, afford an enormous amount of mechanical energy. But up to the present time it has been found that the cost of embankments and machinery for utilising tidal action is so great as to prohibit its employment. The direct action of the sun's heat could be employed, but here, again, the cost of utilisation exceeds the value of the power obtained. Considered practically and commercially, there are only three sources of mechanical energy of industrial importance: 1. The muscular

energy of animals. 2. The gravitation of water falling from a higher to a lower level, and automatically restored to the higher level by the sun. 3. The conversion of heat into mechanical energy, the heat being derived from the combustion of fuels.

As to the muscular energy of animals, the question of distribution does not arise. It is convenient, also, to consider heat energy before considering water power.

Solid Fuel.—By far the most important source of mechanical energy is solid fuel, and chiefly the various descriptions of coal. Coal is obtainable in very many localities, and is transportable anywhere at comparatively small cost. There are, however, certain disadvantages in obtaining energy directly from coal. First of all, there is the fact that, when burned in an open furnace, one fifth to one fourth of the heat escapes with the products of combustion. Next, there is the fundamental disadvantage of the transformation of heat into mechanical energy by a steam-engine, that at most three eights to four fifths of the heat supplied can be transformed, the remainder being rejected in the condenser. The three tenths of the whole heat of the fuel which it is possible to transform by a steam-engine is further reduced by imperfections and losses in the steam engine itself. Then the attendance required in the case of steam engines and boilers, the risk, the difficulty of preventing smoke and of disposing of ashes, are all drawbacks to the general use of steam power.

Gaseous Fuel.—Many of the disadvantages of solid fuel are diminished by employing the coal to produce gas, and using the gas in internal furnace or gas engines. Gas can be transported with great convenience in pipes, and gas engines require less attendance, and work with a greater temperature range and a higher thermal efficiency than steam engines. In transforming heat into work small gas-engines are enormously more efficient than small non-condensing steam engines. On the other hand, ordinary lighting gas, taxed as it is with costs of distribution due to its ordinary application for lighting purposes, is more expensive for a given calorific value than raw coal. The cost of ordinary lighting gas is increased, both by the need of a large generating plant, to meet the excessive fluctuation of demand for lighting, and by the large distributing charges involved in supplying a very great number of small consumers. If gas were made specially for heating and power purposes—either coal gas at low luminous power, or water gas, or producer gas—it could probably be distributed to power users at less than half the present price of coal gas. Used in gas engines, it would then compete, on nearly equal terms as regards cost, with solid coal, and would have many subordinate advantages.

M. Aimé Witz has shown by direct experiment that a gas-engine worked with Dowson gas will give an effective horse power, at a total cost, including all charges for fuel, interest, and depreciation, not greater than that at which an effective horse-power can be obtained by a good boiler and good compound steam-engine. It is impossible to predict how far gas engines will replace steam engines, but at present they have two disadvantages. They are more restricted in size than steam-engines, and they work less economically with light loads.

Production of Power by Burning Town Refuse.—There is another source of heat energy—another fuel—to which Prof. G. Forbes has called special attention—that is, town or ashbin refuse. In addition to ordinary sewage, which is got rid of in well known ways, there is in towns a large quantity of refuse which can only be got rid of effectually and innocuously by burning. Even when the heat generated is wasted, it appears that burning is the least costly method of refuse disposal. It is a fuel, therefore, which, like water power, costs nothing except for the machinery for utilising it.

Various forms of destructors have been tried. It appears that for successful and inoffensive working it is necessary to use a large quantity of air—7lb. or 8lb. per pound of refuse—and that combustion is best effected by a forced draught. Then a large quantity of products of combustion escape from the furnace at a high temperature. By interposing a steam boiler between the furnace and the chimney a by no means unimportant amount of heat can be utilised.

Mr. Watson gives some data of the heat developed in the working of Horsfall furnaces at Leeds, but they are not quite complete or consistent. He states that calculation from an analysis of the escaping gases showed that 4,800lb of water could be evaporated by the heat produced by the combustion of a ton of ashbin refuse. In this calculation it appears that the data assumed were, that in a destructor cell burning six tons of refuse in 24 hours, the escaping gases contained 4·8 per cent. of carbonic acid. The quantity of air passing into the furnace is stated to be 44 tons per day, and the temperature of the gases 2,000deg. The total weight of the furnace gases must then have been 44 + 6 = 50 tons per 24 hours, or say, 4,600lb. per hour; 4·8 per cent. of carbonic acid corresponds to 1·3 per cent. of carbon. Hence the carbon in the furnace gases must have been 0·013 × 4,600 = 59·8lb. per hour. The combustion of this would yield 14,500 × 59·8 = 867,100 thermal units. But also according to the data 4,600lb. of furnace gases were raised from 60deg. to 2,000deg. per hour. This would require 2,231,000 thermal units. These quantities are irreconcileable, and it would seem that either the quantity of air or its temperature have been over estimated. It is true that the heat carried into the furnace by the steam jet has to be deducted from the latter quantity in finding the heat disengaged by the ashbin refuse. From some other experiments it appears that the steam-jet may have delivered 250lb. of steam per cell per hour. The total heat of this would be 287,500 thermal units. If this is deducted from the 2,231,000 thermal units, it still leaves an enormous discrepancy.

Mr. Watson made some other experiments at Oldham. Six cells were used, burning 1½ tons of refuse per hour. The gases passed through a multitubular boiler, 7ft. in diameter and 12ft. long, and the feed was measured by a meter. The temperature of the gases was 2,019deg. before reaching the boiler, and 900deg. after leaving it. Thus only about two-thirds of the available temperature range was utilised. In two trials the mean evaporation was found to be 2,780lb per hour. Deducting 1,500lb. of steam used for the steam-jets, there was a surplus evaporation of 1,280lb. per hour, or, say, 50 h.p. of energy from six cells burning 1½ tons per hour. If a boiler with larger heating surface had been used, possibly an evaporation one third greater would have been obtained, or, say, 3,700lb. per hour. Deducting 1,500lb. used in the steam jets, there would be a surplus or available steam supply of 2,200lb. per hour, or, say, 88 h.p. from six cells burning 1½ tons of refuse per hour. This gives about 40lb. of refuse per effective horse-power hour.

Now the chief difficulty in using the available energy of destructors is this: The refuse must be burned at a regular and almost uniform rate. But demands for power for most purposes are varying demands. It is because later a method of storing heat is to be considered that destructors have been referred to in some detail.

(*To be continued.*)

BLACKPOOL TRAMWAYS.

The number of electrical tramways in this country is so small that little difficulty occurs in watching the working of each one. Just about 12 months ago the Corporation of Blackpool appointed Mr. Hesketh to take charge of the tramway line, and at the end of his first 12 months' appointment he has reported upon his work. The following abstract of accounts, taken from this report, shows approximately the 12 months' working cost and receipts:

APPROXIMATE ABSTRACT OF ACCOUNTS.

(The total car miles from September 9, 1891, to August 22, 1892, were 102,790, and the total traffic receipts for the same period were £6,578. 16s. 1d.)

		1892-3.
Car miles, September 9 to August 22		115,196
Total traffic receipts		£7,033 17 1

Total		£4,061 15 11

The report explains that to the expenditure shown items for depreciation and sinking fund must be added, and comments upon some of the individual items, such as car miles, receipts, and wages, having increased, but undoubtedly the most important part of the report is that under the head "Suggestions," as follows:

Suggestions.—The committee will pardon my drawing their attention to the following points deserving of their most careful consideration: (*a*) That even with the greatest care and closest supervision the present channel system is not a success; (*b*) that the present method of gearing is far from satisfactory, and should not be continued in any future renewals; (*c*) that a single line cannot be worked without loss of time, and therefore great inefficiency.

To meet these points I venture to suggest that—1. In considering any new system special consideration should be given to (*a*) a centre channel of such construction as Brain's system; or (*b*) to an overhead conductor so arranged as not to offend the eye or appear unsightly, say, for instance, an overhead wire fastened to brackets extended from the promenade arc lamp pillars. 2. That new cars should have a single reduction gearing with V spurs or a worm gearing. The former is the more efficient and, in my opinion, the better system. 3. The question of a double line ca[illegible] tained until the scheme for widening the prome[illegible]

We only note that these sugg[illegible] experience, and they are empha[illegible]

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET.

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

THE OTHER SIDE.

That Prof. J. S. Burdon-Sanderson would deliver an interesting, if not a memorable, address at Nottingham was to be expected. With this address as a whole we have nothing to do. It is outside our particular domain, and had it not contained an aside with which we disagree, we should not have commented upon it. Prof. Burdon-Sanderson in an aside once or twice in his address trespassed upon a topic with which the public is not unfamiliar, and which seems to have a peculiar fascination for certain scientific men, many, if not most of whom, are constant patrons of the British Association. Their cry, consistent and persistent, is: Let us dip our hands into the public purse. This is how Prof. Sanderson puts it: "The wealthiest country in the world, which has profited more—vastly more—by science than any other, England stands alone in the discredit of refusing the necessary expenditure for its development, and cares not that other nations should reap the harvest for which her own sons have laboured." The president then went on to press the claims of physicists and of chemists, and later of biologists, to laboratories endowed by the State. Of course, these laboratories are to be "on a scale commensurate with the practical importance" of each science. Ordinarily, the Governments of England have been vilified as stingy, as uninterested and deaf to the claims of science. Prof. Sanderson is not so bad as some of the speakers at these meetings. He is not more than half-hearted in his advocacy, and we think few people who have studied the question will agree to go even as far as he does. Do these men who urge this and that Government grant ever trouble to compare the position of England with the position of those places they dangle before us as edifying? Has England done nothing for science? What of Greenwich, what of the Geological Survey, what of Kew, what of the "Challenger" and similar expeditions, what of its laboratories at Kensington, its grants here, and there, and everywhere? Look, again, at her educational endowments. Is it so necessary for the State to maintain schools, when there are so many richly-endowed universities, colleges, and schools? Are our professors paid for giving so many lectures, or are they supposed to be investigators as well? What are the fellowships of our universities provided for if it be not to enable men who have shown talent to continue their studies? Who are these men who want a physical, a chemical, a biological laboratory? Have they no opportunities to experiment now? Is it likely the nation is going to equip and endow laboratories for eager young men to carry on experiments at someone else's cost, and to run off to the Patent Office to patent the results obtained? Many of the very men who advocate national laboratories are the very men who degrade science and drag it to the dust. They are satisfied with nothing, and claim for their miserable discoveries an infallibility that renders them the laughing-stock of business men. It is not for the good of science or the welfare of humanity, it is not from a patriotic love of country that these men cry "Give! give!" Their only desire is

to line their own pockets at the least trouble to themselves. We are quite sure Prof. Sanderson has not viewed the question in this light. In the quiet, peaceful shade of the university he has learned to love science for the sake of science, can see how with certain facilities more can be done, but he has yet to live in the centre of the business part of the kingdom, and hear how emphatically and universally the proceedings of the younger race of professors, and especially of those with a leaning towards physics, are condemned. How can Prof. Sanderson urge a biological laboratory when his views of the subject are expressed in these words: "I think it not unlikely that the only effect of what I have said may be to suggest to some of my hearers the question, What is the use of such enquiries? Experimental psychology has, to the best of my knowledge, no technical application. The only satisfactory answer I can give is that it has exercised, and will exercise in future, a helpful influence in the science of life." In another part of this address we are told: "It is possible that many members of the association are not aware of the unfavourable, I will not say discreditable, position that this country at present occupies in relation to the scientific study of this great subject—the causes, and mode of prevention of infectious diseases." This is another insinuation with which we disagree. England is not so behindhand as is made out, and when it comes to practical work England is not at all behind. It may be very well to hint that Pasteur and others have made a great fuss about inoculation, but as a matter of fact none of the inoculists or microbe investigators have satisfied the world as to their theories or actions. Tell the truth about these matters. If an Englishman suggests in his modest way some new views nobody takes any notice of him. His own countrymen, instead of testing the value of these views, won't look at them, and wait for a boom from France or Germany. We think we know pretty fairly the sanitary conditions of continental towns, and in our opinion that condition is, on the whole, far and away inferior to that of English towns. This to us is sufficient proof that England is not one whit inferior in sanitary knowledge, and, what is more, in sanitary practice, to other nations. Lastly, we differ entirely to the conclusions that the earnest science student's question "is ever 'how,' rather than 'why.'" He is no true student if he does not prefer the "why" to the "how." When he knows the "why" he may be able to influence the "how"; but till he can do that, his studies, his knowledge, and his labours are lost.

It would come better before the public if this agitation for laboratories came from other sources. Have, for example, the steel, iron, and other manufacturers in metals asked for a physical laboratory; have the cotton or woollen manufacturers, the dyers, the papermakers asked for a chemical laboratory; have medical men or sanitarians asked for a biological laboratory? Do these men not recognise the paucity of knowledge, or is such recognition only to be found among a few professors, some of whom want berths for themselves or their friends? One in a million improvements in industrial operations may come from professorial laboratory work, but as a matter of fact the remainder come from the factory. The men in the latter from day to day know what they want, and try to solve the problem put before them by that want; the men in the laboratory imagine that whatever they do is wanted. The real wants of the factory do not come before them, and never will, unless we come to the old-womanish legislation that seems to be prevailing at present, when the State does everything. The manufacturer wants to know himself, and use his knowledge; he is not so anxious that all his competitors should know, and not at all anxious to give every problem to a central body to solve and publish broadcast. There is a mistaken idea about that a national laboratory will lead to discoveries that may revolutionise industrial operations. Such discoveries have been made; but most improvements are of a different character, and are due to the men continually engaged in the industry. What is to be the definite work of these proposed laboratories? Greenwich provides the nautical almanack; the Geological Survey and Kew provide definite information. This provision of definite information constitutes a difference between these and laboratories which would have merely a roving commission.

REVIEWS.

Elementary Lessons, with Numerical Examples in Practical Mechanics and Machine Design. By R. G. BLAINE, M.E. New edition. Cassell and Co.

Prof. Perry, in his introduction to Mr. Blaine's book, has a sentence referring to authors of books on mechanical subjects which we much appreciate. He says: "It is perfectly well known that the sort of knowledge which such authors try to give is treated with a certain amount of contempt by all practical engineers." This book has an object: to assist the scheme of teaching at the Finsbury Technical College, where we are told two lectures are followed by two hours' numerical work, which again is followed by three hours' laboratory work per week. Mr. Blaine has collected in this book notes of lectures or lessons, and numerical examples based thereon—principally numerical examples. These, we are told, and so far as we have examined them told truly, are of a very practical nature, intended to be similar to those the student will meet with in practical work. We could wish there were more books of the kind, for we are assured that exactness in mental conception is greatly assisted by constant solution of numerical examples. Without such paper work the student thinks loosely rather than accurately. He is totally unable to shake off and consign to oblivion those things that concern him not, and for ever he fears to run alone. The examples given in this book could with advantage be largely extended. Only one short section deals with electrical subjects, and we cannot quite determine the claim for new matter in this section, the numerical examples being under a dozen. The value of the book is, however, not in one section, but as a whole, treating shortly, as it does in the notes, and by a number of numerical examples, a very large range of subjects coming under the head of mechanical engineering.

Gas and Electric Light.—Mr F. L. Linging told the shareholders of the Crystal Palace District Gas Company last week that the competition of the electric light and oil had made no difference to the company during the past half-year.

THE BRITISH ASSOCIATION.

On Wednesday the sixty-third session of the British Association commenced its labours at Nottingham with the presidential address of Prof. J. S. Burdon Sanderson. The address is of great interest to that section of scientific workers whose labours are devoted to biological studies, and bad it not advocated the initiation of laboratories under State aid—a subject dealt with elsewhere—we could have found no words but of praise for this address. As usual, the presidents of Sections A and G in their addresses dealt with subjects not widely separated from electrical matters—in fact, very closely related to them, and these addresses we herewith reproduce :

Address to the Mathematical and Physical Section.

BY R. T. GLAZEBROOK, M.A., F.R.S., PRESIDENT OF THE SECTION.

Before dealing with the subject which I hope to bring to your notice this morning, I wish to express my deep regret for the circumstances which have prevented Prof. Clifton, who had accepted the nomination of the council, from being your president this year. It was specially fitting that he who has done so much for this college, and particularly for this laboratory in which we meet, should take the chair at Nottingham. The occasions on which we see him are all too seldom ; and we who come frequently to these meetings were looking forward to help and encouragement in our work, derived from his wide experience. You would desire, I feel sure, that I should convey to him the expressions of your sympathy. For myself I must ask that you will pass a lenient judgment on my efforts to fill his place. Let me commence, then, with a brief retrospect of the past year and the events which concern our section. From the days of Galileo the four satellites of Jupiter have been objects of interest to the astronomer. Their existence was one of the earliest of the discoveries of the telescope, they proved conclusively that all the bodies of the solar system did not move round the earth. The year which has passed since our last meeting is memorable for the discovery of a fifth satellite. It is a year to-day (September 13-14, 1892) since Prof. Barnard convinced himself that he had seen with the great telescope of the Lick Observatory this new member of our system as a star of the thirteenth magnitude, revolving round the planet in 11 hours 57 minutes 23 seconds.*

The conference on electrical standards held at our meeting last year has had important results. The resolutions adopted at Edinburgh were communicated to the Standards Committee of the Board of Trade. A supplementary report accepting these resolutions was agreed to by that committee (November 29, 1892), and presented to the President of the Board of Trade. The definitions contained in this report will be made the basis of legislation throughout the world. They have been accepted by France, Germany, Austria, and Italy. There is good reason to believe that the congress at Chicago now being held will ratify them, and then we may claim that your committee, co-operating with the leaders of physical science in other lands, has secured international agreement on these fundamental points. Among the physical papers of the year I would mention a few as specially calling for notice. Mr. E. H. Griffith's redetermination of the value of the mechanical equivalent of heat has just been published,† and is a monumental work. With untiring energy and great ability he struggled for five years against the difficulties of his task, and has produced results which, with the exception of one group of experiments, do not differ by more than one part in 10,000, while the results of that one excepted group differ from the mean only by one part in 4,000. The number of ergs of work required to raise one gramme of water 1deg. C. at 15deg. C. is $4{\cdot}194 \cdot 10^7$. Expressed in foot-pounds and Fahrenheit degrees, the value of J is 778·99. The value obtained by Joule from his experiments on the friction of water, when corrected in 1880 by Rowland so as to reduce his readings to the air thermometer, is 778·5 at 12deg. 7 C. The result at this temperature of Rowland's own valuable research is 780·1. Another satisfactory outcome of Mr. Griffith's work is the very exact accordance between the scale of temperature as determined by the comparison of his platinum thermometer with the air thermometer, which was made by Callendar and himself in 1890, and that of the nitrogen thermometer of the Bureau International at Sèvres.

Another great work now happily complete is Rowland's "Table of Standard Wave-lengths."‡ Nearly a thousand lines have been measured with the skill and accuracy for which Rowland has made himself famous ; and in this table we see the results achieved by the genius which designed the concave grating and the mechanical ingenuity which contrived the almost perfect screw. Those of us who have seen Mr. Higgs's wonderful photographs of the solar spectrum taken with a Rowland grating will rejoice to know that his map also is now finished. Lord Rayleigh's paper on "The Intensity of Light Reflected from Water and Mercury at Nearly Perpendicular Incidence,"§ combined with the experiments on reflection from liquid surfaces in the neighbourhood of the polarising angle,‖ establishes results of the utmost importance to optical theory. "There is thus," Lord Rayleigh concludes, "no experimental evidence against the rigorous application of Fresnel's formulæ,"—for the reflection of polarised light—"to the ideal case of an abrupt transition between two uniform transparent media." Prof. Dewar has, during the year, continued his experiments on the liquefaction of oxygen and nitrogen on a large scale. To a physicist perhaps the most important results of the research are the discovery of the magnetic properties of liquid oxygen, and the proof of the fact that the resistance of certain pure metals vanishes at absolute zero.* The last discovery is borne out by Griffiths and Callendar's experiments with their platinum thermometers.† Mr. Williams's article on "The Relation of the Dimensions of Physical Quantities to Directions in Space,"‡ has led to an interesting discussion. Some of his deductions will be noticed later. The title-page of the first edition of Maxwell's "Electricity and Magnetism" bears the date 1873. This year, 1893, we welcome a third edition, edited by Maxwell's distinguished successor, and enriched by a supplementary volume, in which Prof. J. J. Thomson describes some of the advances made by electrical science in the last 20 years. The subject-matter of this volume might well serve as a text for a presidential address.

The choice of a subject on which to speak to-day has been no easy task. The field of physics and mathematics is a wide one. There is one matter, however, to which for a few minutes I should like to call your attention, inadequately though it be. Optical theories have, since the year 1876, when I first read Sir George Stokes's "Report on Double Refraction,"§ had a special interest for me, and I think the time has come when we may with advantage review our position with regard to them, and sum up our knowledge. That light is propagated by an undulatory motion through a medium which we call the ether is now an established fact, although we know but little of the nature or constitution of the ether. The history of this undulatory theory is full of interest, and has, it appears to me, in its earlier stages been not quite clearly apprehended. Two theories have been proposed to account for optical phenomena. Descartes was the author of the one—the emission theory. Hooke, though his work was very incomplete, was the founder of the undulatory theory. In his "Micrographia," 1664, page 56, he asserts that light is a quick and short vibratory motion, "propagated every way through an homogeneous medium by direct or straight lines extended every way like rays from the centre of a sphere. . . . Every pulse or vibration of the luminous body will generate a sphere which will continually increase and grow bigger, just after the same manner, though indefinitely swifter, as the waves or rings on the surface do swell into bigger and bigger circles about a point on it" ; and he gives on this hypothesis an account of reflexion, refraction, dispersion, and the colours of thin plates. In the same work, page 58, he describes an experiment practically identical with Newton's famous prism experiment, published in 1672. Hooke used for a prism a glass vessel about 2ft. long, filled with water, and inclined so that the sun's rays might enter obliquely at the upper surface and traverse the water. "The top surface is covered by an opacous body, all but a hole through which the sun's beams are suffered to pass into the water, and are thereby refracted" to the bottom of the glass, "against which part if a paper be expanded on the outside there will appear all the colours of the rainbow—that is, there will be generated the two principal colours, scarlet and blue, with all the intermediate ones which arise from the composition and dilating of these two." But Hooke could make no use of his own observation ; he attempted to substantiate it from his own theory of colours, and wrote pure nonsense in the attempt ; and though his writings contain the germ of the theory, and in the light of our present knowledge it seems possible that he understood it more thoroughly than his contemporaries believed, yet his reasoning is so utterly vague and unsatisfactory that there is little ground for surprise that he convinced but few of its truth. And then came Newton. It is claimed for him, and that with justice, that he was the true founder of the emission theory. In Descartes's hands it was a vague hypothesis. Newton deduced from it by rigid reasoning the laws of reflexion and refraction, he applied it with wondrous ingenuity to explain the colours of thin and of thick plates and the phenomena of diffraction, though in doing this he had to suppose a mechanism which he must have felt to be almost impossible, a mechanism which in time, as it was applied to explain other and more complex phenomena, became so elaborate that, in the words of Verdet, referring to a period 100 years later, "all that is necessary to overturn this laborious scaffolding is to look at it and try to understand it." But though Newton may with justice be called the founder of the emission theory, it is unjust to his memory to state that he accepted it as giving a full and satisfactory account of optics as they were known to him. When he first began his optical work he realised that facts and measurements were needed, and his object was to furnish the facts. He may have known of Hooke's theories. The copy of the "Micrographia" now at Trinity College was in the library while Newton was working with his prism in rooms in college, and may have been consulted by him. An early note-book of his contains quotations from it. Still, there was nothing in the theories but hypotheses unsupported by facts, and these would have no charm for Newton. The hypotheses in the main are

* "In general," he says, "the satellite has been faint. . . . On the 13th, however, when the air was very clear, it was quite easy."—*Nature*, Oct. 20, 1892. † *Phil. Trans.*, vol. clxxxiv. ‡ *Phil. Mag.*, July, 1893. § *Ibid.*, Oct., 1892. ‖ *Ibid.*, Jan., 1892.

* *Phil. Mag.*, September, 1892. ‡ *Ibid.*, December, 1892.
† *Ibid.*, October, 1892. § *British Association Report*, 1862.

This address was in the printer's hands when I saw Sir G. Stokes's paper on "The Luminiferous Ether," *Nature*, July 27. Had I known that so great a master of my subject had dealt with it so lately, my choice might have been different ; under the circumstances, it was too late to change.

right. Light is due to wave motion in an all-pervading ether; the principle of interference, vaguely foreshadowed by Hooke ("Micrographia," p. 66), was one which a century later was to remove the one difficulty which Newton felt. For there was one fact which Hooke's theory could not then explain, and till that explanation was given the theory must be rejected; the test was crucial, the answer was decisive. Newton tells us repeatedly what the difficulty was. In reply to a criticism of Hooke's in 1672, he writes: "For to me the fundamental supposition itself seems impossible namely, that the waves or vibrations of any fluid can, like the rays of light be propagated in straight lines without continual and very extravagant spreading and bending into the quiescent medium where they are terminated by it. I mistake if there be not both experiment and demonstration to the contrary. . . . For it seems impossible that any of those motions or pressions can be propagated in straight lines without the like spreading every way into the shadowed medium." Nor was there anything in the controversy with Hooke, which took place about 1675, to shake this belief. Hooke had read his paper describing his discovery of diffraction. He had announced it two years earlier, and there is no doubt in my mind that this was an original discovery, and not, as Newton seemed to imply soon after, taken from Grimaldi; but his paper does not remove the difficulty. Accordingly we find in the "Principia" Newton's attempted proof (lib. ii prop. 42) that "motus omnis per fluidum propagatus divergit a recto tramite in spatia immota"—a demonstration which has convinced but few and leaves the question unsolved as before. Again, in 1690 Huygens puplished his great "Traite de la Lumiere," written in 1678. Huygens had clearer views than Hooke on all he wrote; many of his demonstrations may be given now as completely satisfactory, but on the one crucial matter he was fatally weak. He, rather than Hooke, is the true founder of the undulatory theory, for he showed what it would do if it could but explain the rectilinear propagation. The reasoning of the latter part of Huygens's first chapter becomes forcible enough when viewed in the light of the principle of interference enunciated by Young, November 12, 1801, and developed, independently of Young, by Fresnel in his great memoir on "Diffraction," in 1815; but without this aid it was not possible for Huygens's arguments to convince Newton, and hence in the "Opticks" (second edition, 1717) he wrote the celebrated Query 28: "Are not all hypotheses erroneous in which light is supposed to consist in pressure or motion propagated through a fluid medium? If it consisted in motion propagated either in an instant or in time it would bend into the shadow. For pressure or motion cannot be propagated in a fluid in right lines beyond an obstacle which stops part of the motion, but will bend and spread every way into the quiescent medium which lies outside the shadow." These were his last words on the subject. They prove that he could not accept the undulatory theory; they do not prove that he believed the emission theory to give the true explanation. Yet, in spite of this, I think that Newton had a clearer view of the undulatory theory than his contemporaries, and saw more fully than they did what the theory could achieve if but the one difficulty were removed. This was Young's belief, who writes: *"A more extensive examination of Newton's various writings has shown me that he was in reality the first who suggested such a theory as I shall endeavour to maintain; that his own opinions varied less from this theory than is now almost universally believed; and that a variety of arguments have been advanced as if to meet him which may be found in a nearly similar form in his own works." I wish to call attention to this statement, and to bring into more prominent view the grounds on which it rests, to place Newton in his true position as one of the founders of the undulatory theory.

The emission theory in Newton's hands was a dynamical theory; he traced the motion of material particles under certain forces, and found their path to coincide with that of a ray of light, and in the "Principia," prop. xcvi., Scholium, he calls attention to the similarity between these particles and light. The particles obey the laws of reflexion and refraction; but to explain why some of the incident light was reflected and some refracted Newton had to invent his hypothesis of fits of easy reflexion and transmission. These are explained in the "Opticks," book iii., props. xi., xii., and xiii. (1,704), thus: "Light is propagated from luminous bodies in time, and spends about seven or eight minutes of an hour in passing from the sun to the earth. Every ray of light in its passage through any refracting surface is put into a certain transient constitution or state, which in the progress of the ray returns at frequent intervals, and disposes the ray at each return to be easily transmitted through the next refracting surface, and between the returns to be easily reflected by it. *Definition.*—The return of the disposition of any ray to be reflected I will call its fit of easy reflexion, and those of the disposition to be transmitted its fits of easy transmission, and the space it passes between every return and the next return the interval of its fits. The reason why the surfaces of all thick transparent bodies reflect part of the light incident on them and refract the rest, is that some rays at their incidence are in their fits of easy reflexion, some in their fits of easy transmission."

Such was Newton's theory. It accounts for some or all of the observed facts, but what causes the fits? Newton, in the "Opticks," states that he does not enquire; he suggests, for those who wish to deal in hypotheses, that the rays of light striking the bodies set up waves in the reflecting or refracting substance which move faster than the rays and overtake them. When a ray is in that part of the vibration which conspires with its motion it easily breaks through the refracting surface—it is in a fit of easy transmission; and, conversely, when the motion of the ray and the wave are opposed, it is in a fit of easy reflection. But he was not always so cautious. At an earlier date (1675) he sent to Oldenburg, for the Royal Society, an "Hypothesis explaining the Properties of Light"; and we find from the journal book that "these observations so well pleased the society that they ordered Mr. Oldenburg to desire Mr. Newton to permit them to be published." Newton agreed, but asked that publication should be deferred till he had completed the account of some other experiments which ought to precede those he had described. This he never did, and the hypothesis was first printed in Birch's "History of the Royal Society," vol. iii., pp. 247, 262, 272, etc.; it is also given in Brewster's "Life of Newton," vol. i., App. II., and in the *Phil. Mag.*, September, 1846, pp. 187-213. "Were I," he writes in this paper, "to assume an hypothesis, it should be this if propounded more generally, so as not to assume what light is further than that it is something or other capable of exciting vibrations of the ether. First, it is to be assumed that there is an ethereal medium, much of the same constitution with air, but far rarer, subtiller, and more strongly elastic. . . . In the second place, it is to be supposed that the ether is a vibrating medium, like air, only the vibrations far more swift and minute; those of air made by a man's ordinary voice succeeding at more than half a foot or a foot distance, but those of ether at a less distance than the hundred-thousandth part of an inch. And as in air the vibrations are some larger than others but yet all equally swift . . . . so I suppose the ethereal vibrations differ in bigness but not in swiftness. . . . In the fourth place, therefore, I suppose that light is neither ether nor its vibrating motion, but something of a different kind propagated from lucid bodies. They that will may suppose it an aggregate of various peripatetic qualities. Others may suppose it multitudes of unimaginable small and swift corpuscles of various sizes springing from shining bodies at great distances one after the other, but yet without any sensible interval of time. . . . To avoid dispute and make this hypothesis general let every man here take his fancy; only, whatever light be, I would suppose it consists of successive rays differing from one another in contingent circumstances, as bigness, force, or vigour, like as the sands on the shore . . . . and, further, I would suppose it diverse from the vibrations of the ether. . . . Fifthly, it is to be supposed that light and ether mutually act upon one another." It is from this action that reflexion and refraction come about; "ethereal vibrations are, therefore," he continues, "the best means by which such a subtile agent as light can shake the gross particles of solid bodies to heat them. And so, supposing that light impinging on a refracting or reflecting ethereal superficies puts it into a vibrating motion, that physical superficies being by the perpetual appulse of rays always kept in a vibrating motion, and the ether therein continually expanded and compressed by turns, if a ray of light impinge on it when it is much compressed, I suppose it is then too dense and stiff to let the ray through, and so reflects it, but the rays that impinge on it at other times, when it is either expanded by the interval between two vibrations or not too much compressed and condensed, go through and are refracted. . . . And now to explain colours. I suppose that as bodies excite sounds of various tones, and consequently vibrations in the air of various bignesses, so when the rays of light, by impinging on the stiff refracting superficies, excite vibrations in the ether, these rays excite vibrations of various bignesses . . . therefore, the ends of the capillaments of the optic nerve which front or face the retina being such refracting superficies, when the rays impinge on them they must there excite these vibrations, which vibrations (like those of sound in a trumpet) will run along the aqueous pores or crystalline pith of the capillaments through the optic nerves into the sensorium (which light itself cannot do), and there, I suppose, affect the sense with various colours, according to their bigness and mixture—the biggest with the strongest colours, reds and yellows; the least with the weakest, blues and violets; the middle with green; and a confusion of all with white." The last idea, the relation of colour to the bigness of wave length, is put even more plainly in the "Opticks," Query 13 (ed. 1704): "Do not several sorts of rays make vibrations of various bignesses, which according to their bignesses excite sensations of various colours . . . and, particularly, do not the most refrangible rays excite the shortest vibrations for making a sensation of deep violet; the least refrangible the largest for making a sensation of deep red?"

The whole is but a development of a reply, written in 1672, to a criticism of Hooke's on his first optical paper, in which Newton says: "It is true that from my theory I argue the corporeity of light, but I do it without any absolute positiveness, as the word perhaps intimates, and make it at most a very plausible consequence of the doctrine and not a fundamental supposition." "Certainly," he continues, "my hypothesis has a much greater affinity with his own (Hooke's) than he seems to be aware of, the vibrations of the ether being as useful and necessary in this as in his." Thus Newton, while in the "Opticks" he avoided declaring himself as to the mechanism by which the fits of easy reflection and transmission were produced, has in his earlier writings developed a theory practically identical in many respects with modern views, though without saying that he accepted it. It was an hypothesis; one difficulty remained, it would not account for the rectilinear propagation, and it must be rejected till it did. Light is neither ether nor its vibrating motion; it is energy which emitted from luminous bodies, is carried by wave motion in rays, and falling on a reflecting surface sets up fresh waves by which it is in part transmitted and in part reflected. Light is not material, but Newton nowhere definitely asserts that it is. He "argues the corporeity of light, but without any absolute positiveness."

* *Phil. Trans.*, November 12, 1801.

the "Principia" writing of his particles, his words are: "Harum attractionum haud multum dissimiles, sunt Lucis reflexiones et refractiones"; and the Scholium concludes with: "Igitur ob analogiam quæ est inter propagationem radiorum lucis et progressum corporum, visum est propositiones sequentes in usus opticos subjungere; interea de natura radiorum utrum sint corpora necne nihil omnino disputans, sed trajectorias corporum trajectoriis radiorum persimiles sollummodo determinans."* No doubt Newton's immediate successors interpreted his words as meaning that he believed in the corpuscular theory, conceived, as Herschel says, by Newton, and called by his illustrious name. Men learnt from the "Principia" how to deal with the motion of small particles under definite forces. The laws of wave motion were obscure, and till the days of Young and Fresnel there was no second Newton to explain them. There is truth in Whewell's words ("Inductive Sciences," ii., chap. x.): "That propositions existed in the 'Principia' which proceeded on this hypothesis was with many ground enough for adopting the doctrine." Young's view, already quoted, appears to me more just; and I see in Newton's hypothesis the first clear indication of the undulatory theory of light, the first statement of its fundamental laws. Three years later (1678), Huygens wrote his "Traité de la Lumière," published in 1690. He failed to meet the main difficulty of the theory, but in other respects he developed its consequences to a most remarkable degree. For more than a century after this there was no progress, until in 1801 the principle of interference was discovered by Young, and again independently a few years later by Fresnel, whose genius triumphed over the difficulties to which his predecessors had succumbed, and by combining the principles of interference and transverse vibrations, established an undulatory theory as a fact, thus making Newton's theory a *vera causa*.

There is, however, a great distinction between the emission theory as Newton left it and Fresnel's undulatory theory. The former was dynamical, though it could explain but little; the particles of light obeyed the laws of motion, like particles of matter. The undulatory theory of Huygens and Fresnel was geometrical or kinematical; the structure of the ether was and is unknown; all that was needed was that light should be due to the rapid periodic changes of some vector property of a medium capable of transmitting transverse waves. Fresnel, it is true, attempted to give a dynamical account of double refraction, and of the reflexion and refraction of polarised light, but the attempt was a failure; and not the least interesting part of Mr. L. Fletcher's recent book on double refraction ("The Optical Indicatrix") is that in which he shows that Fresnel himself in the first instance arrived at his theory by purely geometrical reasoning, and only attempted at a later date to give it its dynamical form. "If we reflect," says Stokes,† "on the state of the subject as Fresnel found it and as he left it, the wonder is, not that he failed to give a rigorous dynamical theory, but that a single mind was capable of effecting so much." Every student of optics should read Fresnel's great memoirs. But the time was coming when the attempt to construct a dynamical theory of light could be made. Navier, in 1821, gave the first mathematical theory of elasticity. He limited himself to isotropic bodies, and worked on Boscovitch's hypothesis as to the constitution of matter. Poisson followed on the same lines, and the next year (1822) Cauchy wrote his first memoir on elasticity. The phenomena of light afforded a means of testing this theory of elasticity, and accordingly the first mechanical conception of the ether was that of Cauchy and Neumann, who conceived it to consist of distinct hard particles acting upon one another with forces in the line joining them, which vary as some function of the distances between the particles. It was now possible to work out a mechanical theory of light which should be a necessary consequence of these hypotheses. Cauchy's and the earlier theories do not represent the facts either in an elastic solid or in the ether. At present we are not concerned with the cause of this; we must recognise it as the first attempt to explain on a mechanical basis the phenomena observed. According to his theory in its final form, there are, in an isotropic medium, two waves which travel with velocities $\sqrt{A/\rho}$ and $\sqrt{B/\rho}$, A and B being constants and ρ the density. Adopting Cauchy's molecular hypothesis, there must be a definite relation between A and B. A truer view of the theory of elasticity is given by Green in his paper read before the Cambridge Philosophical Society in 1837. This theory involves the two constants, but they are independent, and to account for certain optical effects A must either vanish or be infinite. The first supposition was, until a few years since, thought to be inconsistent with stability; the second leads to consequences which in part agree with the results of optical experiment, but which differ fatally from those results on other points. And so the first attempt to construct a mechanical theory of light failed. We have learnt much from it. At the death of Green the subject had advanced far beyond the point at which Fresnel left it. The causes of the failure are known, and the directions in which to look for modifications have been pointed out.

Now, I believe that the effort to throw any theory into mechanical form, to conceive a model which is a concrete representation of the truth, to arrive at that which underlies our mathematical equations wherever possible, is of immense value to every student. Such a course, I am well aware, has its dangers. It may be thought that we ascribe to the reality all the properties of the model, that, in the case of the ether, we look upon it as a collection of gyrostatic molecules and springs, or of pulleys and indiarubber bands, instead of viewing it from the standpoint of Maxwell, who hoped, writing of his own model, "that by such mechanical fictions anyone who understands the provisional and temporary character of his hypothesis will find himself helped rather than hindered in his search after the true interpretation of the phenomena." Prof. Boltzmann, in his most interesting paper on "The Methods of Theoretical Physics,"* has quoted these words, and has expressed far more ably than I can hope to do the idea I wish to convey. The elastic solid theory, then, has failed; but are we therefore without any mechanical theory of light? Are we again reduced to merely writing down our equations, and calling some quantity which appears in them the amplitude of the light vibration and the square of that quantity the intensity of the light? Or can we take a further step? Let us enquire what the properties of the ether must be which will lead us by strict reasoning to those equations which we know represent the laws of the propagation of light. These equations resemble in many respects those of an elastic solid; let us, then, for a moment identify the displacement in a light wave with an actual displacement of a molecule of some medium having properties resembling that of a solid. Then this medium must have rigidity or quasi rigidity in order that it may transmit transverse waves; at the same time it must be incapable of transmitting normal waves, and this involves the supposition that the quantity, A, which appears in Green's equations must vanish or be infinite. To suppose it infinite is to recur to the incompressible solid theory; we will assume, therefore, that it is zero. Reflexion and refraction show us that the ether in a transparent medium, such as glass, differs in properties from that in air. It may differ either (1) in density or effective density† or (2) in rigidity or effective rigidity. The laws of double refraction and the phenomena of the scattering of light by small particles show us that the difference is, in the main, in density or effective density; the rigidity of the ether does not greatly vary in different media. Dispersion, absorption, and anomalous dispersion all tell us that in some cases energy is absorbed from the light vibrations by the matter through which they pass, or, to be more general, by something very intimately connected with the matter. We do not know sufficient to say what that action must be; we can, however, try the consequences of various hypotheses. Guided by the analogy of the motion of a solid in a fluid let us assume that the action is proportional to the acceleration of the ether particles relative to the matter, and, further, that under certain circumstances some of the energy of the ether particles is transferred to the matter, thus setting them in vibration. If such action be assumed, the actual density of the ether may be the same in all media, the mathematical expression for the forces will lead to the same equations as those we obtain by supposing that there is a variation of density, and since it is clearly reasonable to suppose that this action between matter and ether is in a crystal a function of the direction of vibration, the apparent or effective density of the ether in such a body will depend on the direction of displacement.

Now these hypotheses will conduct us by strict mathematical reasoning to laws for the propagation, reflexion, and refraction, double refraction and polarisation, dispersion, absorption, and anomalous dispersion and aberration of light which are in complete accordance with the most accurate experiments. The rotary polarisation of quartz, sugar, and other substances points to a more complicated action between the ether and matter than is contemplated above, and accordingly, other terms have to be introduced into the equations to account for these effects. It will be noted as a defect, and perhaps a fatal one, that the connection between electricity and light is not hinted at, but I hope to return to that point shortly. Such a medium as I have described is afforded us by the labile ether of Lord Kelvin. It is an elastic solid or quasi solid incapable of transmitting normal waves. The quantity, A, is zero, but Lord Kelvin has shown that the medium would still be stable provided its boundaries are fixed, or, which comes to the same thing, provided it extends to infinity. Such a medium would collapse if it were not held fixed at its boundaries but if it be held fixed, and if then all points on any closed spherical surface in the medium receive a small normal displacement, so that the matter within the surface is compressed into a smaller volume, there will be no tendency either to aid or to prevent this compression, the medium in its new state will still be in equilibrium, the stresses in any portion of it which remains unaltered in shape are independent of its volume, and are functions only of the rigidity and implicity of the forces which hold the boundary of the whole medium fixed. A soap film affords in two dimensions an illustration of such a medium; the tension at any point of the film does not depend on the dimensions; we may suppose the film altered in area in any way we please—so long as it remains continuous—without changing the tension. Waves of displacement parallel to the surface of the film would not be

* The reflexions and refractions of light are not very unlike these attractions. Therefore, because of the analogy which exists between the propagation of rays of light and the motion of bodies, it seemed right to add the following propositions for optical purposes, not at all with any view of discussing the nature of rays (whether they are corporeal or not), but only to determine paths of particles which closely resemble the paths of rays.—"Principia," lib. i., sect. xiv., prop. xcvi., Scholium.

† "Report on Double Refraction," British Association Report, 1862, p. 254.

* *Phil. Mag.*, July, 1893.

† The equations of motion for a medium such as is supposed above can be written: ρ × acceleration of ether + ρ' × acceleration of matter = Σ B × function of ether displacements, and their differential coefficients with respect to the co-ordinates + Σ B' × similar function for matter displacements. The quantity ρ may be spoken of as the effective ether density, the quantities B as the effective elasticity or rigidity.

transmitted But such a film in consequence of its tension has an apparent rigidity for displacements normal to its surface: it can transmit transverse waves with a velocity which depends on the tension. Now the labile ether is a medium which has, in three dimensions, characteristics resembling those of the two-dimensional film. Its fundamental property is that the potential energy per unit volume in an isotropic body, so far as it arises from a given strain, is proportional to the square of the resultant twist In an incompressible elastic ether this potential energy depends upon the shearing strain. Given such a medium and there is nothing impossible in its conception the main phenomena of light follow as a necessary consequence. We have a mechanical theory by the aid of which we can explain the phenomena; we can go a few steps behind the symbols we use in our mathematical processes Lord Kelvin, again has shown us how such a medium might be made up of molecules having rotation in such a way that it could not be distinguished from an ordinary fluid in respect to any irrotational motion, it would, however, resist rotational movements with a force proportional to the twist, just the force required; the medium has no real rigidity. but only a quasi rigidity conferred on it by its rotational motion. The actual periodic displacements of such a medium may constitute light. We may claim, then, with some confidence to have a mechanical theory of light. But nowadays the ether has other functions to perform, and there is another theory to consider, which at present holds the field Maxwell's equations of the electromagnetic field are practically identical with those of the quasi-labile ether. The symbols which occur can have an electromagnetic meaning; we speak of permeability and inductive capacity instead of rigidity and density, and take as our variables the electric or magnetic displacements instead of the actual displacement or the rotation. Still, such a theory is not mechanical. Electric force acts on matter charged with electricity and the ratio of the force to the charge can be measured in mechanical units. A fundamental conception in Maxwell's theory is electric displacement, and this is proportional to the electric force Moreover, its convergence measures the quantity of electricity present per unit volume, but we have no certain mechanical conception of electric displacement or quantity of electricity, we have no satisfactory mechanical theory of the electromagnetic field. The first edition of the "Electricity and Magnetism" appeared 20 years ago In it Maxwell says: "It must be carefully borne in mind that we have made only one step in the theory of the action of the medium. We have supposed it to be in a state of stress, but we have not in any way accounted for this stress, or explained how it is maintained This step, however, appears to me to be an important one, as it explains by the action of consecutive parts of the medium phenomena which were formerly supposed to be explicable only by direct action at a distance I have not been able to make the next step namely, to account by mechanical considerations for these stresses in the dielectric." And these words are true still But for all this, I think it may be useful to press the theory of the quasi labile ether as far as it will go, and endeavour to see what the consequences must be. The analogy between the equations of the electromagnetic field and those of an elastic solid has been discussed by many writers. In a most interesting paper on the theory of dimensions, read recently before the Physical Society, Mr Williams has called attention to the fact that two only of these analogies have throughout a simple mechanical interpretation These two have been developed at some length by Mr. Heaviside in his paper in the *Electrician* for January 23rd, 1891 To one of them Lord Kelvin had previously called attention ("Collected Papers," vol. iii., page 450)

Starting with a quasi labile ether, then we may suppose that μ, the magnetic permeability of the medium, is $4\pi\rho$,* where ρ is the density, and that K, the inductive capacity, is $1/4\pi B$, B being the rigidity, or the quasi rigidity conferred by the rotation. The kinetic energy of such a medium is $\frac{1}{2}\rho(\dot{\xi}^2+\dot{\eta}^2+\dot{\zeta}^2)$, where ξ, η, ζ are the components of the displacement. Let us identify this with the electromagnetic energy $(\alpha^2+\beta^2+\gamma^2)/8\pi$, α, β, γ being components of the magnetic force, so that $\alpha=\dot{\xi}$, $\beta=\dot{\eta}$, $\gamma=\dot{\zeta}$. Then the components of the electric displacement, assuming them to be zero initially, are given by

$$f=\frac{1}{4\pi}\left(\frac{d\dot{\zeta}}{dy}-\frac{d\dot{\eta}}{dz}\right), \text{ etc. };$$

that is, the electric displacement, $\mathfrak{D}$, multiplied by 4π is equal to the rotation in the medium. Denote this by Ω. The potential energy due to the strain is

$$\tfrac{1}{2}B\Omega^2, \text{ or } \tfrac{1}{2}16\pi^2 B\mathfrak{D}^2;$$

and on substituting for B this becomes

$$\frac{1}{2}\frac{4\pi}{K}\mathfrak{D}^2,$$

which is Maxwell's expression for the electrostatic energy of the field Thus, so far, but no farther, the analogy is complete, the kinetic energy of the medium measures the magnetic energy, the potential energy measures the electrostatic energy. The stresses in the ether, however, are not those given by Maxwell's theory.

In the other form of the analogy we are to take the inductive capacity as $4\pi\rho$, and the magnetic permeability as $1/4\pi B$. The velocity measures the electric force, and the rotation the magnetic force, so that electrostatic energy is kinetic, and magnetic energy potential. Such an arrangement is not so easy to grasp as the other. Optical experiments, however, show us that in all probability it is ρ, and not B, which varies, while from our electrical measurements we know that K is variable and μ constant; hence this is a reason for adopting the second form. In either case we look upon the field as the seat of energy distributed per unit of volume according to Maxwell's law. The total energy is obtained by integration throughout the field. Now we can transform this integral by Green's theorem to a surface integral over the boundary, together with a volume integral through the space; and the form of these integrals shows us that we may look upon the effects, dealing, for the present, with electrostatics only as due to the attractions and repulsions of a certain imaginary matter distributed according to a definite law over the boundary and throughout the space To this imaginary matter, then, in the ordinary theory we give the name of electricity. Thus an electrified conducting sphere, according to these analogies, is not a body charged with a quantity of something we call electricity, but a surface at which there is a discontinuity in the rotation impressed upon the medium, or in the flow across the surface; for in the conductor a viscous resistance to the motion takes the place of rigidity. No permanent strain can be set up

From this standpoint we consider electrical force as one of the manifestations of some action between ether and matter. There are certain means by which we can strain the ether the friction of two dissimilar materials, the chemical action in a cell are two; and when adopting the first analogy, this straining is of such a nature as to produce a rotational twist in the ether, the bodies round are said to be electrified: the energy of the system is that which would arise from the presence over their surfaces of attracting and repelling matter, attracting or repelling according to the inverse square law. We falsely assign this energy to such attractions instead of to the strains and stresses in the ether. Such a theory has many difficulties. It is far from being proved; perhaps I have erred in trespassing on your time with it in this crude form. The words of the French *savant*, quoted by Poincare, will apply to it: "I can understand all Maxwell except what he means by a charged body." It is not, of course, the only hypothesis which might be formed to explain the facts, perhaps not even the most probable. For many points the vortex sponge theory is its superior. Still I feel confident that in time we shall come to see that the phenomena of the electromagnetic field may be represented by some such mechanism as has been outlined, and that confidence must be my excuse for having ventured to call your attention to the subject.

Address to the Mechanical Science Section.

BY JEREMIAH HEAD, M.INST.C.E., PAST-PRES INST MECH.E., F.C.S., PRESIDENT OF THE SECTION.

This section of the British Association for the Advancement of Science was founded with the object of making more widely known and more generally appreciated, all well ascertained facts and well-established principles having special reference to mechanical science. As president of the section for the year, it becomes my duty to inaugurate the proceedings by addressing you upon some portion of the scientific domain to which I have referred, and in which your presence here indicates that you are all more or less interested.

Mechanical Science.

The founders of the British Association no doubt regarded the field of operations which they awarded to Section G as a not less purely scientific one than those which they allotted to the other sections. And, indeed, mechanical science studied, say, by Watt, was as free from suspicion of commercial bias as chemical science studied, say, by Faraday. But whatever may have been the original idea, the practice of the section has recently been to expend most of its available time in the consideration of more or less beneficial applications of mechanical science, rather than of the first principles thereof. Our section has become more and more one of applied rather than of pure science. None of the other sections is free from this fault, if fault it be (which I do not contend or admit), but Section G seems to me to be beyond all question, and beyond all others, the section of applied science.

The charter of the Institution of Civil Engineers commences by reciting that the object of that society is "the general advancement of mechanical science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a civil engineer, being the art of directing the great sources of power in nature for the use and convenience of man" It seems that in 1828, when the institution was incorporated, the term "mechanical science" had a wider meaning than it is now usually understood to have. For, according to the charter, the art of directing the great sources of power in nature is only a particular species of knowledge which "mechanical science" includes. In 1836, or eight years later, the founders of our section adopted the term without again defining it. Probably they accepted the careful definition of the Great George-street Institution Time has shown the wisdom of that decision. For we civil engineers and other frequenters of Section G in active practice need far more knowledge than mechanical science can teach us in the ordinary or narrow sense of the term. Our art in its multifarious branches requires, if success is to be attained, the acquisition and application of almost all the other sciences which belong to the fields of research relegated to the other sections. For how could the gigantic engineering structures of modern times be designed without recourse to mathematics, or steam and other motors without a know

* If we adopted Mr. Heaviside's rational system of units the 4π would disappear.

or modern metallurgical operations be conducted without chemistry, or mining without geology, or communications by rail, ship, and wire be established and carried on with all parts of the world without attention to geography, or extensive manufacturing enterprises be developed if the laws of economics were neglected?" As to biological studies, they seem at first sight to have but little to do with mechanical science. It might even be thought that the civil engineer could afford altogether to neglect this part of the work of the association. But I trust I shall be able to show you before I finish that any such view is absolutely untenable.

Mechanisms in Nature.

Indeed, I hope, in the course of this address, to satisfy you that mechanical science is largely indebted to mechanisms as they exist in nature, if not for its origin, at all events for much of its progress hitherto, and that nature must still be our guide. Mechanical science has been built up entirely upon observation and experiment, and the natural laws which have been induced therefrom by man. The lower animals in their wild condition work with tools or appliances external to their bodies to but a very slight extent, and man in a primitive or savage state does the same. But many, if not most, animals can be taught to use mechanisms if carefully trained from infancy. Thus, the well known donkey at Carisbrooke Castle draws water from a deep well by a treadmill arrangement just as well as a man could do it. He watches the rope on the barrel till the full pail rises above the parapet of the well, then slacks back a little to allow it to be rested thereon, and only then leaves the drum and retreats to his stable. But, according to his attendant, four years were needed for his education, and unless it had been commenced early it would have been useless. I have seen a canary gradually lift from a little well, situated a foot below its perch, a thimble full of water by pulling up with its beak bit by bit, a little chain attached to it, and securing each length lifted with its foot till it could take another pull. When the thimble reached its perch level the bird took a drink and then let it fall back into the well. Numerous other examples will doubtless occur to you. But though animals can be taught to make use of mechanical appliances provided for them—a fact which shows the existence in their brains of a faculty corresponding in kind, if not in degree, to the mechanical faculty in man—they rarely on their own initiative make use of anything external to their bodies as tools, and still more rarely, if ever, do they make, alter, or adapt such mechanical aids. Mr C. Wood, of Middlesbrough, informs me that certain crows which frequent oyster beds on the coast of India wait until the receding tide covers the oysters, which still remain open for a time. A crow will then put a pebble inside one, and, having thus gagged it and secured his own safety, will proceed to pick it out and eat it at leisure. A monkey will crack a nut between two stones and will hurl missiles at his enemies. But in some countries he is systematically entrapped by tying to a tree a hollow gourd containing rice, and having a hole large enough for his hand, but too small for his clenched fist, to pass through. He climbs the tree and grasps the rice and remains there till taken, being too greedy, and not having sufficient sense, to let go the rice and withdraw his hand. This is on a par with the snuff taking imbecile, described by Hugh Miller,* whom the boys used to tease by giving him a little snuff at the bottom of a deep tin box. The imbecile would try to get at it for hours without the idea ever occurring to him that he might achieve his object by turning the box upside down.

All animals are, however, in their bodily frames, and in the intricate processes and functions which go on continuously therein, mechanisms of so elaborate a kind that we can only look and wonder and strive to imitate them a little here and there. The mechanism of their own bodily frames is that with which the lower animals have to be content, and whilst they are in the prime of life and health, and in their natural environment, it is generally sufficient for all their purposes. Man has a still more perfect, or, rather, a still more versatile bodily mechanism, and one which in a limited environment would be equally sufficient for his needs. But he has also an enterprising and powerful mind which impels him to strive after and enables him to enjoy fields of conquest unknown to, and uncared for, by the relatively brainless lower animals. Urged on by these superior mental powers, man must soon have perceived that by the use of instruments he could more quickly and easily gain his ends, and he would not be long in discovering that certain other animals, such as the ox and the horse, were teachable and his willing slaves, provided only he fed and trained them and treated them kindly. First, in common with other animals, he would find out that stones and sticks were of some use as weapons and tools, then he would go further and utilise skins and thongs for clothing and harness; and by selecting and modifying his stones and sticks he would form them into rough implements, which would enable him to cut down trees and to make rude huts and boats. Animals caught and domesticated would first be taught to haul light logs along the ground, then to move heavier ones on rollers; and later, in order to avoid the necessity for continual replacement of the rollers, the wheel and axle would be gradually developed. The mechanical nomenclature of all languages is largely derived from the bodies of men and other animals. From this it is clear that animals have always been recognised as mechanisms, or as closely related thereto. The names borrowed from them generally indicate a resemblance in form rather than in function, though not invariably so. Thus in our own language we have the "head" of a ship, a river, a lake, a jetty, a bolt, a nail, a screw, a rivet, a flight of stairs, and a column of water; the brow of an incline, the crown of an arch; the toe of a pier, the foot of a wall; the forefoot, heel, ribs, waist, knees, skin, nose, and dead eyes of a ship, also turtle-backs and whale backs; the jaws of a vice; the claws of a clutch; the teeth of wheels; necks, shoulders, eyes, nozzles, legs, ears, mouths, lips, cheeks, elbows, feathers, tongues, throats, and arms; caps, bonnets, collars, sleeves, saddles, gussets, paddles, fins, wings, horns, crabs, donkeys, monkeys, and dogs; flywheels, running nooses, crane necks, grasshopper engines, etc.

Not only has our mechanical nomenclature been largely taken from animals, but many of our principal mechanical devices have pre existed in them. Thus, examples of levers of all three orders are to be found in the bodies of animals. The human foot contains instances of the first and second, and the forearm of the third order of lever. The patella, or kneecap, is practically a part of a pulley. There are several hinges and some ball and socket joints, with perfect lubricating arrangements. Lungs are bellows, and the vocal organs comprise every requisite of a perfect musical instrument. The heart is a combination of four force-pumps acting harmoniously together. The wrist, ankle, and spinal vertebræ form universal joints. The eyes may be regarded as double lens cameras, with power to adjust focal length, and able, by their stereoscopic action, to gauge size, solidity, and distance. The nerves form a complete telegraph system with separate up and down lines and a central exchange. The circulation of the blood is a double line system of canals, in which the canal liquid and canal boats move together, making the complete circuit twice a minute, distributing supplies to wherever required, and taking up return loads wherever ready without stopping. It is also a heat distributing apparatus, carrying heat from wherever it is generated or in excess to wherever it is deficient, and establishing a general average, just as engineers endeavour, but with less success, to do in houses and public buildings. The respiratory system may be looked upon as that whereby the internal ventilation of the bodily structure is maintained. For by it oxygen is separated from the air and imparted to the blood for conveyance and use where needed, whilst at the same time the products of combustion are extracted therefrom and discharged into the atmosphere. Mastication, which is the first process in the alimentary system is, or rather should be, a perfect system of cutting up and grinding, and to assist and save animal, and especially human, mastication is the chief aim and object of all the gigantic milling establishments of modern times. The later alimentary processes are rather chemical than mechanical, but still the successive muscular contractions, whereby the contents of the canal are forced through their intricate course, are distinctly mechanical, and may have suggested the action of various mechanisms which are used in the arts to operate on plastic materials, and cause them to flow into new forms and directions.

The superiority of man to the lower animals can only have become conspicuous and decided when he began to use his inventive faculties and to fashion weapons and implements of a more efficient kind than the sticks and stones which they also occasionally use. But human races and individuals were never equally endowed by nature. Some individuals would have greater inventive powers than others, and these and their posterity would gradually become dominant races. Large masses of mankind are still more or less in the position of primeval man, which, if we accept the conclusions of Darwin, Lubbock, and other modern scientists, we must regard as one of barbarism; for they are still without tools, appliances, and clothes, except of the most elementary kinds, and mechanical science might almost be non existent so far as they are concerned.* It would obviously be impossible for me to treat of or call attention even to an infinitesimal extent to the results of mechanical science which surround us now so profusely, and which make our life so different from that of primeval man; and even if it were possible, it would be quite unnecessary. We have all grown up in a mechanical age. We are so familiarised with artificial aids that we have come to regard them as part of our natural environment, and their occasional absence impresses us far more than their habitual presence. I propose, with your leave, to proceed to the consideration of how far man is, in his natural condition, and has become by aid of mechanical science, able to compete successfully with other and specially endowed animals, each in its own sphere of action.

Bodily Powers of Man and other Animals.

The bodily frame of man is adapted for life and movement only on or near to the surface of the earth. Without mechanical aids he can walk for several hours, at a speed which is ordinarily from three to four miles per hour. Under exceptional circumstances he has accomplished over eight miles† in one hour, and an average of 2¾ miles per hour for 141 hours.‡ In running he has covered about 11½ miles in an hour. In water he has proved himself capable of swimming 100 yards at the rate of three miles per hour, and 22 miles at rather over one mile per hour. He can easily climb the most rugged mountain path and descend the same. He can swarm up a bare pole or a rope, and when of suitable physique and trained from infancy can perform those wonderful feats of strength and agility which we are accustomed to expect from acrobats. He has shown himself able to jump as high as 6ft 2¾in from the ground, and over a horizontal distance of 23ft. 3in., and has thrown a cricket ball as far as 382½ft. before it struck the ground.§ The attitude and action of a man in throwing a

§ *Chambers's Encyclopædia*, "Athletic Sports."

stone or a cricket ball, where he exerts a considerable force at several feet from the ground, to which the reaction has to be transmitted and to which he is in no way fastened, are unequalled in any artificial machine. The similar but contrary action of pulling a rope horizontally, as in "tug of war" competitions, is equally remarkable. So also the power of the living human mechanism to withstand widely diverse and excessive strains is altogether unapproachable in artificial constructions. Thus, although fitted for an external atmospheric pressure of about 15lb. per square inch, he has been able, as exemplified by Messrs. Glaisher and Coxwell in 1862, to ascend to a height of seven miles, and breathe air at a pressure of only 3¼lb. per square inch and still live. And on the other hand, divers have been down into water 80ft. deep, entailing an extra pressure of about 35lb. per square inch, and have returned safely. One has even been to a depth of 150ft., but the resulting pressure of 67lb. per square inch cost him his life.[*]

Recent fasting performances (if the published records are to be trusted) are not less remarkable when we are comparing the human body as a piece of mechanism with those of artificial construction. For what artificial motor could continue its functions 40 days and nights without fuel, or, if the material of which it was constructed were gradually consumed to maintain the flow of energy, could afterwards build itself up again to its original substance? These and other performances are, when considered individually and separately, often largely exceeded by other animals specially adapted to their own limited spheres of activity. The marvel is not, therefore, that the human bodily mechanism is capable of any one kind of action, but that, in its various developments, it can do all or any of them, and also carry a mind endowed with far wider powers than any other animal.

Animals other than man are also adapted for life and movement on or about the surface of the earth. This includes a certain distance below the ground, as in the case of earthworms; under the water, as in the case of fish; on the water, as in the case of swimming birds; and in the air as with flying birds. As far as I know, no animal burrows downwards into the earth to a greater depth than 8ft.,[†] and then only in dry ground. Man is naturally very ill adapted for boring into the earth as the earthworm does. Indeed, without mechanical aids he would be helpless in excavating or in dealing with the accumulations of water which are commonly met with underground. But by aid of the steam engine for pumping, for air compressing, ventilating, hauling, rock boring, electric lighting, and so forth, and by the utilisation of explosives, he has obtained a complete mastery over the crust of the earth and its mineral contents down to the depth where, owing to the increase of temperature, the conditions of existence become difficult to maintain. I have said that on land man, unaided by mechanism, has been able to cover about 11½ miles in one hour. Two miles he has been able to run at the rate of nearly 13 miles per hour, and 100 yards at the rate of over 20 miles per hour.[‡] But the horse, though he cannot walk faster than man, nor exceed him in jumping heights or distances, can certainly beat him altogether when galloping or trotting. A mile has been galloped in 103 seconds, equal to 35 miles per hour, and has been trotted in 124 seconds, equal to 29 miles per hour.[§] There are many other animals, such as ostriches, greyhounds, antelopes, and wolves, which run at great speeds, but reliable records are difficult to obtain, and are scarcely necessary for our present purpose.

Mechanical Aid without Extraneous Motive Power.

Let us now consider how man's position as a competitor with other animals in speed is affected by his use of mechanical aids, but without any extraneous motive power.

Locomotion on Land.—Where there is a stretch of good ice, and he is able to bind skates on his feet, he can thereby largely augment his running speed. This was exemplified by the winner of the match for amateurs at Haarlem last winter, who accomplished the distance of 3·1 miles at the rate of about 21 miles per hour. But the most wonderful increase to the locomotive power of man on land is obtained by the use of the modern cycle. Cycling is easily performed only where roads, wind, and weather are favourable. But similar conditions must also be present to secure the best speed of horses, with which we have been making comparison. One mile has been cycled at the rate of 27·1 miles per hour, 50 at 20,[¶] 100 at 16·6,[¶] 388 at 12·5,[**] and 900 at 12·43 miles per hour. The recent race between German and Austrian cavalry officers on the high road between Vienna and Berlin has afforded an excellent opportunity to judge of the speed and endurance of horses as compared with men over long distances. Count Starhemberg, the winner, performed the distance, about 388 miles, in 71·33 hours, equal to 5·45 miles per hour. He rested only one hour in twelve. His horse, though successful, has since died.[††] Lawrence Fletcher cycled, also along the high roads, from Land's End to John o' Groats' house, 900 miles, in 72·4 hours, equal to 12·43 miles per hour, or more than double the distance that the Count rode, and at above double the speed. To the best of my knowledge he still lives, and is no worse for his effort. The horse in this case would have to carry extra weight equal to one-sixth of his own, and the cyclist equal to a quarter of his own. But the horse carried himself and his rider on his own legs, while the cyclist made his machine bear the weight of itself and rider. Herein was probably the secret of his easy victory. With the very remarkable exception of long-distance cycling, which is of limited application, man relying on his own bodily strength cannot successfully compete with other animals which, like the horse, are specially fitted for rapid land locomotion. His only alternatives are either to utilise the horse and ride or drive him, and so get the benefit of his superior strength and speed, or to use his own inventive faculty and construct appliances altogether apart from animal mechanism. In either case he virtually gives up the contest as a self-moving animal, and to a great extent abandons himself to be carried by others or by inanimate machinery. Nearly 70 years ago mankind came to this conclusion, and the modern railway system is the result. The locomotive will go at least double the speed of the racehorse. It will carry, not only itself, but three or four times its own weight in addition, but will go not two or three, but 100 miles or more without stopping, if only the road ahead be clear. And the iron horse is fed and controlled without even so much exertion as that put forth by a man on a horse of flesh and bone.

Locomotion on Water.—Let us now consider the powers of man relatively to other animals in moving upon and through the great waters with which three-fourths of the earth's surface is covered. Here he is in competition with fishes, aquatic mammals, and swimming birds. I have already stated that, unaided by mechanism, he has shown himself able to swim, for short distances at the rate of three and long distances (22 miles) at the rate of one mile per hour. He has also given instances of being able to remain under water for 4½ minutes.[*] Credible eye witnesses inform me that porpoises easily overtake and keep pace with a steamer going 12½ knots, or, say, over 14 miles per hour, for an indefinite length of time. This is five and fifteen times the maximum swimming speed of a man for short and long distances respectively. No doubt the form and surface of a fish whose main business is swimming offer less resistance, and his muscular power is more concentrated and better applied towards propulsion in water than is the case with man, whose body is also adapted for so many other purposes. I am further informed by Mr. Nelson, of Redcar, a naturalist who has made the experiment, that it is impossible for an ordinary sea boat, rowed by two men and going at five miles per hour, to overtake the aquatic bird called the Great Northern Diver, when endeavouring to make his escape by alternately swimming on the surface and diving below. His speed is therefore nearly double the short and five times the long distance speed of unaided man in water. As regards remaining under water, fishes properly so called have unlimited powers, and even aquatic mammals, such as whales, can remain under for 1½ hours. Using only his own strength, but assisting himself with mechanical devices, man has been able to increase considerably his speed as a swimming animal. Mr. John McCall, of Walthamstow, informs me that in 1868 he constructed and repeatedly used an apparatus which acted like the tail of a fish. It consisted of a piece of whalebone, having a broad yet thin and elastic blade tapering into a shank like the end of an oar. The blade was 15in. wide and 4ft. long, including the shank. To the end of the latter a horizontal cross bar, 15in. long, was fitted, and leather pockets were provided at the ends for the feet. By swimming on his back and striking out alternately with his legs, he was able, with the assistance of this apparatus, to keep up with a sea boat pulled by two men at about four miles per hour. By means of boats, which he propels by oars or sculls, and notwithstanding the increased weight, and therefore displacement, involved by them, man has been able to increase his speed on the surface of the water to a maximum of about 12 miles per hour for about four miles distance, under favourable circumstances. So, by supplementing his bodily powers by means of mechanical aids, such as the diving bell and the diving helmet, dress, and air pump, or by the portable self-acting apparatus used with such good effect in the construction of the Severn tunnel, man has been able to approach very nearly to the natural diving powers of, at all events, aquatic animals, except that he cannot move about in subaqueous regions with anything approaching their ease and celerity. Invariably, on water, as almost invariably on land, man is quite unable to compete in power of locomotion with other specially adapted animals, whether or not he avails himself of mechanical aids, so long as his own bodily strength is the only motive power he employs. He has gradually come to recognise this fact, and to see that he must use his inventive faculties, and find new and powerful motors external to himself if he would really claim to dominate the great waters of the earth. The fastest mechanism of any size, animal or man made, which, as far as I know, has ever cut its way through the waters for any considerable distance, is the torpedo boat "Ariete," made by Messrs. Thornycroft and Son, of London, in 1887. It has a displacement or total weight of about 110 tons, and machinery capable of exerting 1,290 effective horse-power, or 11·7 h.p. per ton of weight or displacement; or, to put it in another form, an effective horse-power is by it obtained from a weight of 191lb., which includes vessel, machinery, fuel, stores, and attendants. The speed accomplished at the trials of this little craft, being the average of six one-mile tests, was 26·18 knots, or 30·16 miles per hour.[†] As might be expected, it resembles a fish, in that its interior is almost exclusively devoted to the machinery and accessories necessary for propulsion. During the trials the water, fuel, stores, and other ponderable substances carried amounted to 17·35 tons. Two similar boats were able to make the voyage to South America by themselves, though at much slower speed and replenishing their fuel on the way. No fish or swimming bird can

match this performance. And inasmuch as 191lb. of dead weight produced 1 h.p., as compared with from 150lb. to 250lb. in certain flying birds, it would seem that with suitable adaptations the "Ariete" might even have been made to navigate the air instead of the water.* But I will revert to this subject later on. Where safety in any weather, and passenger and cargo-carrying powers are aimed at, as well as, or prior to, the utmost attainable speed—and these must ever be the leading features of ocean transit steamers if they are to attain commercial success—there I must refer you to those magnificent examples of naval architecture which are more or less familiar to you all, and of which we, as a maritime nation, are so justly proud. If for example, we turn our attention for a moment to the new Cunard liners, the "Campania" and "Lucania," having each a weight or displacement of 18,000 tons and 24,000 effective horse power, or 1.33 h.p. per ton of displacement, we shall find that with the commercial advantages alluded to they obtain a maximum speed of 22.5 knots, or about 26 miles per hour. If, instead of 1.33 effective horse power per ton of displacement, they were provided with eight times that amount, or 10.64 h.p. per ton, thereby sacrificing passenger and cargo accommodation and making them nearly as full of propelling machinery as the "Ariete" torpedo boat, and if it were then found possible to apply this enormous power effectively, then there is every reason to believe they would accomplish for short distances double the speed, or say, 45 knots, or about 52 statute miles, per hour. By inventing and utilising mechanical contrivances entirely independent of his own bodily strength, man can now pass over the surface of the waters at the rate of over 500 knots per day, and at the same time retain the comforts and conveniences of life as though he were on shore. He has in this way beaten the natural and specially fitted denizens of the deep in their own element as regards speed and continuity of effort. But he is still behind them as to safety. We do not find that fishes or aquatic mammals often perish in numbers, as man does, by collisions in fogs, or by being cast on lee shores and rocks by stress of weather. Shall we ever arrive at the point of making ocean travelling absolutely safe? The Cunard Company is able to boast that from its commencement, 53 years ago, it has never lost a passenger's life or a letter, a statement which gives ground for hope that almost absolute safety is attainable. But, on the other hand, other owners of almost equal repute (not excluding the British Admiralty) are ever and anon losing magnificent vessels on rocks, in collisions, by fire, and even by stress of weather, in a way which makes us doubt whether it is possible for Britannia, or anyone else, really to "rule the waves." In one way the chances of serious disaster have been of late largely diminished, and here, again, nature has been our teacher. The bodies of all animals, except the very lowest, are symmetrically formed on either side of a central longitudinal plane. Each important limb is in duplicate, and if one side is wounded the other can still act. We have at last found out the enormous advantage and increased safety of having the whole of our ship-propelling machinery in duplicate, and our ships made almost unsinkable by one longitudinal and numerous transverse bulkheads.

Locomotion in Air.—I now come to consider what is the position of man as regards locomotion in and through the great atmospheric envelope which surrounds the earth in comparison with animals specially fitted by Nature for such work. Nature seems never to bestow all her gifts on one individual or class of animals, and she never leaves any entirely destitute. For instance, the serpent, having no limbs whatever, would seem at first sight to be terribly handicapped; yet, in the language of the late Prof. Owen, "it can out-climb the monkey, out-swim the fish, out-leap the jerboa, and, suddenly loosing the close coils of its crouching spiral, it can spring into the air and seize the bird on the wing."† Here we have the spiral spring in nature before it was devised by man. Flying animals seem to conform remarkably to this law. Thus we have birds, like the penguin, which dive and swim, but cannot fly; others, like the gannet, which dive, swim, fly, and walk; others, like the ostrich, which run, but can neither fly nor swim; and numberless kinds which can fly well, but have only slight pedestrian powers. Man, unaided by mechanisms, can, as we have seen, walk, run, swim, dive, and jump, and perform many remarkable feats; but for flying in the air he is absolutely unfitted. All his attempts (and there have been many) have up to the present been unsuccessful, whether or not he has availed himself of mechanical aids to his own bodily powers. It is said that a certain man fitted himself with apparatus in the time of James VI. of Scotland, and actually precipitated himself from the cliff below Stirling Castle, in sight of the king and his courtiers; but the apparatus collapsed, and he broke his leg, and that was the end of the experiment. But why should not man fly? It is not that he does not desire to do so. For every denizen of our precarious British climate, when he has noticed the ease with which swallows and other migratory birds fly off on the approach of winter, hundreds and even thousands of miles to the sunny south, must have wished he could do the same. One reason why we cannot fly, even with artificial aids, such as wings, is that, as in the case of the penguin or the ostrich, our bodily mechanism is specialised and our muscular power diffused in other directions, so that we could not actuate wings of sufficient area to carry us even if we had them. M. de Lucy, a French naturalist, has shown that the wing-area of flying animals varies from about 49 square feet per pound of weight in the gnat, and five square feet in the swallow, to half a square foot per pound of weight in the Australian crane, which weighs 21lb., and yet flies well. If he were to adopt the last or smallest proportion, a man weighing 12 stone would require a pair of wings each of them 14ft. long by 3ft. broad, or double the area of an ordinary room door, to carry him, without taking into account the weight of the wings themselves. In flying birds there is a strong tripod arrangement to secure firm points of attachment for the wings, and a deep keel in the breast bone, to which the large pectoral muscles are secured. Think of the wings I have described and the absence of pivots, keel, and muscles in man, and it will be tolerably obvious why he cannot fly, even with artificial wings. But it might be contended that a man's strength is in his legs rather than in his arms, and that it is conceivable that a successful flying apparatus might be made if adapted for the most, instead of the least, favourable application of his bodily strength. According to D. K. Clark,* a labourer working all day exerts on an average .13 h.p. The maximum power of a very strong man for a very short time is .46 h.p. According to Dr. Haughton,† the oarsmen in a boatrace of one mile, rowed in seven minutes, exerted each .26 h.p. Suppose we take the rowing case as the maximum maintainable for, say, seven minutes, by a man weighing 168lb. Then in flight he would have to sustain a weight of

$$\frac{168}{.26}=646\text{lb.}$$

per horse power exerted, besides the weight of the apparatus.

Now, we shall find later that no birds support even half that weight per horse power which they have the power to exert, and that recent aeroplane experiments prove its impossibility. On the ground, therefore, that he is too heavy in proportion to his strength, it is clear that man is unfitted for flight, as well as because his limbs are not adapted for it. It does not follow, however, that by aid of mechanisms apart from his own body, and worked by power independent of his own strength, man may not imitate, compete with, and even outdo the fowls of the air. Let us consider a few facts showing what birds can do. A gannet hovers in the air above the sea. Suddenly he nearly closes his wings, swoops down, and with a splash disappears below the surface. Shortly after he reappears with a fish in his mouth, which he swallows in a few gulps; then, after swimming on the surface a little, he reascends into the air to repeat the operation. The swallow rises into the air with a few rapid movements of the wings, then slides down as though on an aerial switchback, and then up again till he nearly reaches his original height, or he circles round by raising one wing, like a runner rounding a curve. The condor vulture, which measures sometimes 15ft. across the wings, will fly upwards till quite out of sight. A flock of cranes have been seen migrating at a height of three miles, and proceeding apparently without any movement of the wings. The peregrine falcon will swoop down upon a partridge, and, missing it by a doubling movement of the latter, will slide upwards, thus converting his kinetic into new potential energy. He will then turn and descend again, this time securing his prey. Mr. J. E. Harting, one of the principal British ornithological authorities, has, after careful investigation, arrived at the conclusion that the speed of falcons in full flight is about 60 miles per hour.‡ Mr. W. B. Tegetmeier, another well-known authority, gives the results of a number of experiments on the speed of homing pigeons, made under the auspices of the United Counties Flying Club in 1883. The average speed of the winner in 18 races was 36 miles, and the maximum 55 miles per hour. The greatest distance flown was 309 miles. The albatross, the largest web-footed bird, measuring sometimes 17ft. from tip to tip of wing, and weighing up to 20lb., frequently accompanies ocean steamers from the Cape to Melbourne, a distance of 5,500 knots, without being seen to rest on the way. An American naturalist, Mr. J. Lancaster, who spent no less than five years on the west coast of Florida, in order to study the habits of aquatic and other birds which frequent those shores, arrived at the following conclusions, viz.:§ Though all birds move their wings sometimes, many can remain indefinitely in the air, with wings extended and motionless, and either with or without forward movement. This he calls "soaring." The wing area of soaring birds varies from one to above two square feet per pound of weight. The larger the wings per pound of weight, the greater the power to soar. The heavier the bird, the steadier his movements. Soaring birds always face the wind, which, if they do not move forward or downward, must not blow at a less speed than two to five miles per hour. Mr. Lancaster specially watched a flock of buzzards about 30ft. above his head, waiting for him to leave the body of a dead porpoise. Their wings were about 5ft. from tip to tip, and their average weight about 6lb. During three hours at midday, when the wind which they faced was very strong, they flapped their wings about 20 times each. Later, during two hours, when the wind had subsided, they never moved them at all. Mr. Lancaster timed frigate birds, and found them able to go at the rate of 100 miles per hour, and that on fixed wings; he is of opinion that at all events up to that speed they can fly just as fast as they please. He says further that the same birds can live in the air a week at a time, night and day, without touching a roost, and that buzzards, cranes, and gannets can do the same for several hours at a time. The observed facts relating to the phenomena of flight

* M. Normand, of Havre, is building for the French Government two torpedo boats, each having a displacement of 125 tons and 2,717 effective horse power, or 21.7 h.p. per ton of displacement. This is equivalent to 1 h.p. per 103lb., and is still within the limits of weight permissible for aerial flight.—See *Times*, *June 10, 1893.*

are still but very imperfectly understood. That a bird should be able to maintain a downward pressure on the air sufficient to counteract the effect of its own weight, and a backward pressure sufficient to force itself forward at such speeds as I have named, seems wonderful enough when it is known that it continuously operates its wings; but that it should be able to do the same without any muscular movement at all is almost incomprehensible. It seems to be an instance of the suspension of the laws of gravity and of the existence of cause without effect, and of effect without cause. It is not a case of flotation like a balloon, for any bird falls to the earth like a stone when shot. Mr Lancaster suggests that the bird's own weight is the force which enables him to counteract the effect thereof, but this explanation is, I confess, beyond my comprehension. It seems to me that for every pound of his weight pressing downwards there must be an equivalent force pressing upwards. This can be produced only by his giving downward motion to the air previously at rest, or by his arresting previous motion of air in an upward direction. The latter alternative involves the supposition that the air currents which soaring birds face are not, as Mr. Lancaster believes, always horizontal, but must have, to some extent, an upward direction. If a parachute were falling in a current of air which was moving upwards at the same rate as the parachute fell, it would obviously retain its level, yet gravity would be acting. So, if a bird with extended wings were sliding down a stream of air which was tending upwards at the same angle and same velocity, the phenomenon of soaring would be produced.

(To be continued.)

BUSINESS NOTES.

Commercial Cable Company.—A quarterly dividend of 1¼ per cent. is announced, payable on the 2nd prox.

Western and Brazilian Telegraph Company.—The receipts for the week ended September 8 were £1,919.

Bowness.—The surveyor, in his monthly report to the Local Board, states that all the street lamps are now supplied with the electric light.

The British Association. The Town Council of Ipswich have resolved to invite the British Association to hold its meeting for 1895 at Ipswich.

Wolverhampton.—The Town Council have received formal sanction to borrow £1,928 for the purchase of land for the purposes of electric lighting.

Taunton.—The Taunton Corporation are now prepared to receive applications for electric lighting, and they will be ready to supply electricity after the 30th inst.

Stonehouse.—Mr. Bone suggested, at a meeting of the Local Board on Tuesday, that as they were going to light the Town Hall by electricity, the lamp at the entrance should be similarly illuminated.

Appointment.—It is stated that one of the electricians trained under Mr. W. Chew, M.I.E.E., at the old Blackpool Corporation Electricity Works, has been offered a post of electrical engineer to an installation in a Lancashire town.

Resignation.—We are informed that Mr. R. Turnbull has resigned his position with the New Zealand Electrical Syndicate, Limited, and the Gulcher Company, and that his address in future will be Custom House Quay, Wellington, New Zealand.

Worcester. The Highways and Bridges Committee of the Worcester County Council have granted the application made by the Corporation of Worcester for permission to break up the Malvern and Worcester road for the laying of electric light mains.

Zambesia.—A contract was to be signed yesterday between the Portuguese Government and the Zambesi Company for the laying of a submarine cable to establish telegraphic communication with Zambesia, and for the construction of land telegraph lines in that region.

Winchcombe.—The ratepayers have voted that the lighting inspectors should make a trial of oil illumination for the streets instead of gas, about which some dispute has arisen with the gas company. Electric lighting does not appear to have been considered.

Bangor.—At a meeting of the City Council last week, the accountant reported that the estimated cost of painting parts of the reading room and fixing electric communication between the reading room and house, etc., would be about £12. It was resolved that the work be done.

Bradford.—The Corporation are inviting tenders, to be sent in by Tuesday next, for the supply of switchboards. Plans and specifications may be seen at the office of the electrical engineer at the Town Hall, Bradford, or copies may be obtained on payment of one guinea.

City and South London Railway Company. The receipts for the week ending September 10 were £751, against £768 for the same period last year, or a decrease of £17. The total receipts for the second half year of 1893 show an increase of £429 over those for the corresponding period of 1892.

Tenders for Cables.—The Secretary of State for Foreign Affairs has received from her Majesty's Ambassador at Madrid a copy of a Spanish Royal Order, setting forth the conditions for the construction and laying of submarine telegraph cables uniting the islands of Luzon and Las Visayas, tenders for which are invited. The order can be seen on personal application at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Burnley.—It was suggested by Councillor Harker at a meeting last week of the Town Council, that the two arc lamps in the centre of the town should be placed higher. Alderman Lancaster said they had not decided to light all the streets with electricity, but to supply it to the tradesmen, but Councillor Altham thought that the Council could surely see their way to placing arc lamps at the principal points in the centre of the town.

Portsmouth. The Electric Lighting Committee of the Town Council submitted on the 5th inst. certificates from Messrs. Waller and Manville for payment to the contractor for the erection of the electric lighting station in Gunwharf-road of the sum of £500, and to the contractors for the boilers, engines, and electrical plant of the sum of £2,500 on account of the work executed, and recommended that such amounts be paid. This was agreed to.

Bolton. A special meeting of the Bolton Town Council was held on Wednesday to approve of the proceedings of the Gas and Lighting Committee, which has let contracts in connection with an extensive scheme of electric lighting which the Corporation are about to embark upon. Borrowing powers to the extent of £40,000 have been applied for to the Local Government Board, and an extensive system of mains will very shortly be laid in the principal thoroughfares.

Bath. When the Surveying Committee of the Town Council met last week, Mr. Sturges mentioned, in reply to a question raised by Mr. Taylor at the previous meeting, that the testing of the electric light for the public lamps by Mr. Gatehouse was carried out at the works; for private lighting the testing was done at his own office. He mentioned that the men at the works were determined to get more pay, and in consequence the company could not get the men to attend to their duty quite as well as they wished they could. However, that trouble was over now.

Telegraph Accounts. An estimate of the revenue and expenditure of the Post Office Telegraphs for the year ending March 31, 1893, has been issued from the Treasury as a parliamentary paper. The total revenue is estimated at £2,528,423 and the total expenditure at £2,683,789. The percentage of total expenditure to total revenue is 106.14, and there is estimated a deficit in the net revenue of £155,366. The percentage of salaries, etc., to total revenue is 67.95. The estimated cost of telegraphic extension is £96,989, the actual cost for the year 1891-92 having been £156,383.

Dorman and Smith.—Owing to the increasing demands for their manufactures, and recognising the desirability of personally consulting their friends both in London and the provinces as to particulars of their requirements, Messrs. Dorman and Smith, on the termination of their agreement with Mr. H. R. Wood, have placed this department under the control of Mr. A. H. Dorman. Although occupying the present London offices, Mr. Dorman will make periodical visits to the chief centres of the electrical industry, and also be in constant communication with their head office and works in Manchester.

Blackburn. The Town Council on the 7th inst. adopted the following minutes of the Gas Committee: "That in the event of the Town Council authorising this committee to proceed with the extension of the gasworks, a portion of the No. 1 gasworks be used as a temporary site for the electric lighting installation, and that it be an instruction to the town clerk to issue advertisements in accordance with the plans and specifications which have been approved by this committee for the necessary electric lighting machinery; the necessary building and alteration of the gasworks to be carried out by the Corporation's own workmen."

Harrogate. At the quarterly meeting on Monday of the Town Council the sub-committee reported that they had conferred with Mr. Wilkinson with reference to his appointment as electrical engineer to the Corporation, and had agreed with him as to terms on which he should prepare and carry out the installation in accordance with his report previously made. It was decided to approve the report of the sub-committee, and to enter into an agreement with Mr. Wilkinson accordingly, the design and construction of the necessary building to be carried out by the borough surveyor, and the works of the engineering department by Mr. Wilkinson.

Scarborough.—At a meeting of the special sub-committee of the Town Council as to the proposed telegraph wire to the South Cliff Post Office, the town clerk had submitted a draft of a proposed letter to the Postmaster-General calling his attention to the injurious effect which the proposed line of telegraph would have upon the houses adjoining the back streets if the telegraph wires were carried overhead, and suggesting that the matter had better be referred to the county court judge, as provided by the Telegraph Act, 1878. It was resolved that the letter as drafted be forwarded to the Postmaster-General and this recommendation has been adopted by the Town Council.

Cardiff.—Alderman Carey read on Monday, at a meeting of the County Council, a letter which had appeared in the *Times* protesting against the agreement about to be entered into between the Post Office authorities and the National Telephone Company, which, it was alleged, would prove injurious to the public in years to come. He pointed out that Manchester, Liverpool, and other large centres had consulted the members of Parliament in the matter, and seeing that it affected them in the matter of tearing up their streets and roads, he moved that the town clerk should communicate with other municipalities with a view to their taking common action in the matter. A resolution to this effect was adopted.

International Electric Syndicate.—This Company was formed in April, 1891, to acquire patents and improvements in the construction of accumulators, and generally to carry on the business

of electrical machinery manufacturers. The nominal capital was £12,000, divided into £10 shares, but only 807 were allotted, and of that number 800 were issued to the vendors as fully paid. No statement of affairs has yet been filed, because, it is said, the only officers of the company who appear to be able to file the same have left the country. Meetings of creditors and shareholders were held on Wednesday, and the company was left in the hands of the official receiver to be wound up in the usual manner.

Lincoln.—The Town Council on the 7th inst. considered a notice from the London and Brush Provincial Electric Lighting Company, Limited, stating their intention to apply to the Board of Trade for a provisional order to authorise the supply of electricity within the city of Lincoln and certain adjacent parishes, and a letter from Messrs. Andrew and Trotter asking the Corporation to consent to the application. It was decided to refuse the request inasmuch as the Corporation themselves possess special facilities for lighting the city with electricity, and are quite prepared to undertake the work as soon as they are satisfied that the true interests and advantages of the inhabitants demand the supply of such a mode of lighting in the city and adjacent parishes.

Halifax.—A meeting of the Halifax Town Council in committee was held on Tuesday. A question having arisen through the proposal of a company to lay an overhead electric trolley system, with the permission of the authorities, Councillor H. E. Greenwood moved that the question be adjourned *sine die*. Councillor Maude seconded the motion. Alderman Tattersall submitted an amendment to the effect that in the opinion of the Council the construction of an efficient tramway system was desirable as soon as the finances of the borough would admit of one being laid, but it should be under the control of the Corporation. Councillor Lister seconded this. The amendment was lost by a large majority, only five voting for it. The original proposition was then carried unanimously.

Lighting at Blackpool.—The questions of electric lighting and gas and tramways were discussed last week by the Town Council. It was anticipated that the arc lighting would be ready before October. Mr. Councillor Pearson said that if they could make a good display, amounting to an illumination worthy of thousands of visitors coming down to see it, it would be worthy of the effort. The pillars were fixed in position, the lamps were going through some tests, and it was intended that they should be perfect before being fixed on the promenade. Mr. Alderman Parkinson, in moving the adoption of the minutes of the Markets and Gas Committee, said that the members of the committee felt that there was room for electricity and gas, and they hoped that electricity would prove a success. They did not think the demand for gas had reached the maximum yet.

Montrose.—A report from Mr. Wm. A. Bryson, electrical engineer, Glasgow, in reference to the suggestion that the electric light should be introduced into Montrose was read at a meeting of the Town Council on Monday. In the course of his report, Mr. Bryson stated that he was of opinion that it would be neither satisfactory nor economical to adopt water as the motive power. He therefore suggested the laying down of a small central lighting station with steam engines and boilers, or preferably gas engines and producers, the total cost of which he estimated would be £6,000, or if a large battery of accumulators was added the cost would be increased to £8,000. Details were also given as to the annual cost of maintenance, and Mr. Bryson works out a credit balance to the town of £352, and the price he estimates at 6d. per unit, equivalent to gas at 5s. per 1,000ft. It was agreed to let the report lie over until a future meeting.

Dawlish.—The Local Board, at a meeting last week, had under consideration a letter from Messrs. Rose and Co., of Manchester, stating that they had noticed that the Board had resolved to erect a fire alarm in the town, and offering to provide a double bell with fittings for £11. 15s. The National Telephone Company wrote offering to fix and maintain six electric bells at the addresses pointed out by the committee for the sum of £5 per annum for five years; otherwise, they would erect and maintain four electric bells and three telephones for the sum of £6 per annum for five years. Mr. H. James, of St. Thomas, Exeter, wrote offering to fit electric fire bells in the houses of 11 members of the fire brigade, the bells to be rung from any suitable place that may be decided on. He would also fix all necessary wires, bells, etc., and maintain same in a working order for the sum of £6. 15s. Or he would fix bells to six of the nearest firemen to the call station and maintain same at an annual rental of £3. These prices would include the use of a street fire alarm. Mr. Bayldon proposed that Mr. James's offer be accepted. Mr. Hearn supported, and the motion was carried.

Lighting at Blackburn.—We are informed that the Wray Electrical Engineering Company, of Soho Works, Thornton road, Bradford, have secured the contract for the erection of a complete electric light plant at the extensive cotton mills of Messrs. E. Heyworth and Sons, Audley Hall Mills, Blackburn. The installation will consist of about 750 lamps of 16 c.p., with separate slow speed vertical engine, supplied by Messrs. Robey and Co., of Lincoln, and specially designed for this installation in combination with a direct-driven dynamo. The firm are also engaged on the wiring and fitting up of the Mersey Rice and Flour Mill, Liverpool, owned by Mr. Edward Hutchinson. This will be one of the largest electric light installations in corn mills in the North, and will consist of two 400-light dynamos and storage for 400 lights, together with a separate engine and dynamo for lighting the mill in the daytime. The Wray Electrical Engineering Company have recently completed a similar installation at Messrs. H. Leetham and Sons, Hungate Flour Mills, York. The company are very busy, being engaged on the following installations: Messrs. Pattinson and Winter, corn millers, Whitehaven; Messrs. Nicholson and Birkett, Kirton Lindsey, Gainsborough; Messrs. Goodall's Drug Company, Morley; Messrs. Robinson Bros., Town Corn Mills, Rotherham; and Messrs. J. Wigfull and Sons, Star Corn Mills, Sheffield.

Lighting at Morley.—We give the following information supplementary to that published in our last issue. The Electric Lighting Committee of the Town Council resolved on August 10 that schemes should be invited to be submitted for the electric lighting of the Town Hall and the borough generally, separately, and to pay £100 to the successful competitor. Alderman Schofield, in moving the adoption of the committee's resolution at a meeting of the Town Council last week, said the committee had taken no definite action. Councillor Rhodes seconded the motion. Alderman Dixon thought that spending £100 in that way was a waste of money. If they advertised for competitors to offer schemes, he believed they would get 50 people who would be willing to give them their advice and show them schemes that would be equally as good as those they offered to pay for. He found no other towns in England where they talked about having the electric light giving £100 for a scheme. He was not opposed to the electric light—it might be advantageously applied; but to give £100 for a scheme was monstrous. He proposed an amendment that the minutes be confirmed with the exception of the giving of a premium of £100 to the successful competitor. Alderman Rhodes seconded the amendment, and said there were parties who would be glad to supply all the information they required without being paid for it. On being put to the meeting, the amendment was lost and the minutes confirmed in their entirety.

Edinburgh.—On Monday evening a number of prominent citizens joined the magistrates and Council of Edinburgh in an inspection of the new refuse disposal works at Powderhall. The destructor has now been in operation for some three or four weeks, and the results, it appears, have been in every way satisfactory. With the aid of the electric light, with which the works are fitted, the company had an excellent opportunity of seeing what could be done in the disposal of city refuse by artificial means. At the close of the inspection, Lord Provost Russel delivered a short address. He recalled both the circumstances which led up to the erection of the works—the main difficulty felt by the authorities being that of getting rid latterly of the town refuse—and the character of the opposition originally entertained towards the destructor. Eventually, however, the Corporation saw that the problem had to be solved, and that had been done largely owing to the exertions of Councillor Sloan. His lordship pointed generally to the facilities now afforded for the disposal of refuse, and touched on the question of the utilisation of the surplus power in providing electric light in the immediate neighbourhood of the works. This, however, was a matter that might be further considered when the destructor scheme was further developed, as it would no doubt have to be by and by. Councillor Sloan suggested that the surplus power might be used in supplying electric light to public baths and washhouses in the neighbourhood of a destructor, or in forming an installation for other public purposes.

Electric Lighting in Dundee.—At a meeting of the Lighting Committee of the Dundee Police Commission on the 5th inst., the minute of the sub-committee of the Lighting Committee concerning the lighting of the streets by electricity was submitted. It recommended the erection of the following lamp standards: In Nethergate, 10; Murraygate, five; Reform street, four; Commercial-street, eight; Castle street, three; Whitehall street, three; and Union street, three; in all, 36. The convener explained that in these thoroughfares 123 gas lamps could be dispensed with. He also reported that the expense of erecting the lamps and lighting the thoroughfares mentioned would be, for supplying and erecting 36 lamp standards, £550, supplying light thereto at £20 each, £720. Deducting from this 123 gas lamps at £1. 12s. 6d. each, amounting in the aggregate to £200, there was a balance left of £1,070. He further recommended that the first cost of the lamp standards and their erection should be spread over a period of three years, thus making an annual charge against the scheme for the first three years as follows: One third cost of supplying and erecting lamp standards, £183. 6s. 8d.; expense of supplying light, £720; total £903. 6s. 8d. After taking from that 123 gas lamps, equal to £200, they were left with £703 as the expenditure for the first three years for supplying lamp standards and lighting. The sub-committee recommended that the Commissioners erect the lamps provided the Gas Commissioners supply light at a rate of £20 each. The minute was approved of, and it was remitted to the sub-committee to carry the arrangements into effect. They also resolved to include an addition of 14 lamps to the east and west stations.

Lighting at Glasgow.—Mr. Mitchell, moving the approval of the accounts of the Gas Trust at a meeting of the Town Council last week, referred to the year's operations of the Gas and Electric Lighting Committee. In the electrical department the committee were able to see progress and reasonable prosperity, for a small loss of £1,773 on the first year's operations of such a concern, and the explanations in the report, seemed to point to success at no distant date. The Waterloo street works were now practically fully occupied, and two additional engines and dynamos had been ordered to meet the extra enquiries for the coming winter, so that with steadily increasing business they might hope the electric lighting department would soon be profitable, and advantageous alike to suppliers and consumers in future years. In conclusion, the Gas and Electric Lighting Committee proposed formally to ask the Council to fix the price of gas at 2s. 6d. per 1,000 cubic feet from date of last survey, being a reduction of 3d. from last

year's price, and to continue the price of electric current at 7d per unit, the same as last year. In doing so they wished to express their sense of the valuable work done by the engineer, Mr Foulis, and the works managers; Mr. Fleming, treasurer; Mr. Arnot, electrical engineer, and all other officials, to whom much of this favourable result was due. It might be that in years to come the light of the future might become the light of the present, and the coalmaster and gas lighting things of the past; but however that might be, the committee trusted the Council would ever interest themselves deeply in this great manufacturing department, to which they devoted much time and attention, and in whose continued prosperity and success they would find ample reward. Mr. Fife seconded the motion, which was agreed to.

Whitehaven.—The Town and Harbour Trust last week considered the following minutes of the Electric Lighting Committee: "8th August. The surveyor was directed to order 20 electric meters from Messrs. Ferranti and Co. 14th August. The engineer was authorised to make arrangements with Dr. Hopkinson in regard to the staff required at the electric generating station. Read letter, dated July 12th, from the Furness Railway Company in respect of an easement rent for the electrical cables crossing the Furness Railway at Coach road level crossing, and the surveyor was instructed to reply that no easement charge was due in respect of this. Read letter, dated 10th July, 1893, from Mr Dees, in respect of an easement rent for crossing the arch of a cellar near the Castle Hotel, Corkickle, the property of Lord Lonsdale. Recommended that the terms and conditions as set forth in the letter be accepted. 21st August.—The surveyor submitted an account which he had received from the Whitehaven United Gas Company, Limited, for repairing damage to gas mains alleged to have been caused by trenching for the electric light cables. The surveyor was instructed to return the account, as the committee do not admit any liability." The Chairman moved the confirmation of these minutes. He did not think there was anything in the minutes that called for observation. They were all aware that the light was turned on on Saturday evening, in the public lamps, and he thought with success. The light was in every way a success, and it was very well they had got it going. Mr. Pattinson seconded the motion, which was carried unanimously. The Chairman said that the next business was to provide money for electric lighting. He proposed that the seal of the Board be affixed to four bonds, in favour of the Cumberland Union Bank, of £700 each, making a total of £2,800 that will be required before the end of the month to meet the expenses of balances of contract; but they are drawn in £700 bonds so that the money need only be drawn when it is wanted to hand over to the contractor. Mr. Hastwell seconded the motion, which was agreed to.

Lighting at Bury.—On the 7th inst. the minutes of the Electric Lighting Committee, bearing the date of 17th ult., were presented at a meeting of the Town Council. The minutes comprised the following report of the borough engineer: "In accordance with your instructions, tenders for the supply of electric light plant have been duly advertised for in various engineering and electrical journals, in accordance with the conditions and particulars approved by you, a copy of which, together with the necessary plans of the compulsory area and site of central station, have been issued to each contractor who has made application. Twenty-four copies of conditions, etc., were originally applied for and issued. Of these seven have been returned, as the parties applying were not able to comply with the terms of the specification, being only part makers of electric light plant, and five firms have kept the conditions, but have not sent in any tender. The following 12 firms, which, with one exception, includes the principal contractors for electric plant, have sent in tenders—viz., Mather and Platt, Limited, Manchester; Laing, Wharton, and Down, London; C. A. Parsons and Co., Newcastle-on-Tyne; Manchester Edison-Swan Company, Manchester; Johnson and Phillips, Kent; Siemens Bros. and Co., Limited, London; the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, London and Silvertown; Woodhouse and Rawson, Limited, Manchester; Crompton and Co., Limited, London; Brush Electrical Engineering Company, Limited, London; J. H. Holmes and Co., Newcastle-on-Tyne; John Fowler and Co., Limited, Leeds. These tenders are now before you. It will be in the remembrance of the committee that the conditions left it optional with the various contractors whether they should tender for 'continuous' or 'alternating' currents, as also the kind of engines and dynamos to be employed, giving the reasons for the adoption of the 'system' and type of machinery which they recommended. This leaves the reports and tenders so wide that it will be necessary for a careful analysis of the tenders to be made before any comparisons can be made as to the initial cost of the working expenses hereafter. This is a matter not only requiring so much care and time, and also so thorough a knowledge of the subject, that it can only be done by one trained as an electrical engineer, and it remains with the committee to determine what course shall be adopted, whether (1) they will call in an expert to analyse the reports and tenders and report to them as to the one most applicable to the borough (paying a fee for such examination and report; or (2) whether they will at once appoint a permanent electrical engineer, who shall, in conjunction with myself, carefully examine the tenders and report (the committee, on receipt of such report, if thought necessary, to pay a fee to an expert to confirm, or otherwise, the report to them); or (3) whether they will appoint a consulting engineer, on commission, to whom the whole of the plans, reports, specifications, and tenders shall be handed to report upon, and who shall have full charge of the works from the commencement to the completion." It was resolved that an electrical engineer be advertised for at a salary of £200 per annum.

Telephony at Glasgow.—At a meeting of the Town Council on 7th inst., Councillor Starke moved the adoption of the minutes of the Special Committee on Telephone Service. The minutes detailed the steps taken to procure a telephone license from the Postmaster-General, and also alluded to the consideration of the question of selecting an engineer who could be consulted by the Corporation with reference to the proposed telephone service. Bailie Primrose moved as an amendment that the application to the Postmaster be approved, but that the other portions of the minutes be remitted back to the committee. He contended that all the committee was instructed to do was to make the application to the Postmaster-General. Bailie Graham seconded the amendment, holding that the committee had exceeded its powers. The Council had not committed itself to the principle of whether or not they should go in for a municipal telephone system. Councillor Colquhoun said he could not understand what Bailie Graham meant when he said that the Town Council had not agreed to the principle of facing a municipal telephone system, because if there was one thing clearer than another the step which the Town Council took in authorising the committee to apply for a license was a distinct affirmation of the principle that the telephone in Glasgow might very well be municipalised. Those who supported that agreed that the telephones ought to be in the hands of the Government. They quite recognised that the telephone system was not a purely municipal matter; but that was not the question they were face to face with to-day. The position of the matter was, briefly, that the Postmaster-General had given a license to the National Telephone Company to carry on a telephonic system in Glasgow until the year 1911. At the time when that license was granted licenses were being granted freely to everybody who applied for them, and as a matter of fact there was another licensee in Glasgow, and if he had stuck to his license and carried on his business, the rents would not have been anything like what they were to-day. As a matter of fact, he had a telephone from the other licensee, and he was enabled on that account to make terms which were £7 or £8 cheaper than anybody else connected with the telephone company. That being so, they, as a municipality, would be foolish if they did not, in the exercise of their rights, go to the Postmaster-General and say, "Give us a license; we have as much right to a license as this telephone company." If they got it, they should adopt the best system. They should lay their telephone system for the city on the twin wire system, and when people had had experience of this they would have nothing to do with the existing system, which, as at present used, resulted in the user hearing everybody's message but the one that he wanted to hear. Whether Glasgow got a license or not, the Government would not be prevented from taking over the system in 1911 if they so decided; and, indeed, a municipality would be more easily dealt with than a private company. The Town Council would simply stultify itself by adopting the amendment. They were under a deep debt of gratitude to Councillor Starke for the immense labour he had taken in this matter, and for the pressure he had brought to bear on the Government. The Postmaster-General dared not now refuse Glasgow a telephone license. After further discussion, the minutes were amended so as to read that no engineer should be engaged till the answer of the Government to the application should have been received and a solution thereupon have been come to.

Barrow Lighting.—The subject of electric lighting came up again for consideration at the monthly meeting of the County Council on the 4th inst. In accordance with notice, Councillor Smith moved, "That in order to ascertain whether there is any demand for the electric light a circular be sent to each householder in the centre of the town asking them to state whether they would be prepared to take a supply, and, if so, to what extent." He said after the considerable length of time he had occupied the Council on the two previous occasions in which he had brought the electric light question forward, it was not now necessary for him to take more than one moment in proposing his motion. So far as the discussion went on the two previous occasions, and so far as he had had the opportunity of getting the opinions of members outside, there seemed to be a great unanimity of opinion as to the many advantages obtainable over other sorts of illumination. He would only point out that the issue seemed to be as to whether the present was an opportune time or not. The chief objection before to the scheme proposed was, that although it had been successful in other towns, Barrow was in a different position to other towns, and if it was established here there would be no demand for it. That was the chief objection, and he was now asking the Council to issue circulars to test as to whether his notion that there would be a demand was a correct one or not. Councillor Wansbrough seconded. Alderman Strongitharm said it seemed to him that Councillor Smith had rather put the cart before the horse. At the last meeting of the Council this question of electric lighting was thoroughly discussed, and the Council had a report from the Gas and Water Committee submitted to them dealing with the question. At that time Councillor Smith moved that the Electric Lighting Sub-Committee be authorised to provide a provisional order. The motion, however, was lost by 16 votes to seven, and an amendment by Councillor Wansbrough that the matter be referred to the borough engineer for a report thereon was lost by 17 votes to six. He submitted now that there was no necessity for going on with the matter. At the last meeting he moved the amendment that a provisional order for electric light be not sought, because there was absolutely

demand whatever for it in the town. That seemed to be the view taken by the Council, judging by the large number who voted for the amendment. They had done this previously—24th October, 1890—and circumstances had not changed since then. In that year circulars were issued with the following: "Would you be disposed to take the electric light in the event of its being supplied in accordance with the terms of the annexed letter." Out of 805 circulars issued to householders, and to show the little amount of interest taken in it, 350 were returned with no answer. Only 25, or 3 per cent., replied that they were willing to take the electric light if supplied, 421 stating emphatically "No" (thus 50 per cent. refused to take it), and 350 persons never replied to the circular. He thought that proved pretty conclusively that there was no desire at that time to go in for the electric light. As he pointed out upon the last occasion, it seemed to him that it was very desirable to let the matter rest where it was. It had been already stated that, considering the present position of the town, they should not incur any expenditure further upon current capital account, they having spent £30,000 or £40,000, and practically the whole of which was unremunerative. Already the Electric Lighting Sub-Committee had spent between £40 and £50 in getting information relative to the electric light. He did not think they should go in for it at present, as there was really no legitimate demand for it. If there was a demand it should be made spontaneously by the people of the town. They should memorialise the Corporation if they desired to have the electric light, and the Corporation would take any request into consideration. He should oppose the proposition. After further discussion the motion was adopted.

Electricity and Sewage Disposal. This question was referred to in our last issue in connection with the meeting of the Monmouth Town Council, and we now give the following additional information. Mr. W. Honeyfield (the mayor) said that when last they had the question of drainage before them it was to receive the schemes sent in, in answer to advertisement. In all the schemes sent in they were asked to supply a motive power—either steam, oil, or gas. They had, he thought, sufficient water power running through the town, and he did not know why it could not be utilised, thereby reducing the yearly cost of purification. The only objection he could see to the water being used as a motive power would be by the Board of Conservators. They (the Council) would take the water out at one point and put it in at another, and therefore the Conservators would have no reason to interfere. All the sewage would gravitate to a spot between the Mayhill viaduct and the Redbrook road, and would be there lifted by hydraulic power to just below the Hill Farm, on a piece of land near the viaduct. By selecting that site for the purification works, it was out of sight of the town. They were called upon to provide motive power for the removal of the sewage. If they could get sufficient water power they might try an electrical installation. He was aware that in mentioning electricity he was putting his head into a hornet's nest, but the figures he should roughly put before them would, he believed, justify him in doing so. They had to consider the public good. If they could see their way clear to reducing the public expenditure, it was their duty to do so. He knew that water could be utilised, but he found that the electrical installation for 100 public lamps could not be done so economically as a larger one. The question was, had they sufficient power available to drive an electrical installation of 100 public lamps and 500 private ones? He had been in communication with electrical and hydraulic engineers upon that point, and he thought that from the figures he should place before them (the Council) it would justify him in asking them to appoint a committee to go deeper into the question. As far as he could ascertain, the cost of installation for 600 lamps would be about £2,500; that figure was taken from an installation of 2,000. Consequently it might work out in actual practice higher than it was there. The permanent yearly expenses would be about £382. By combining the electrical station with the purification works, part of the labour would be available to attend to the sewage. The Council paid the gas company something like £320 per year for gas. The income from 500 private lamps at 15s. each would be £375; the total income would be £693. The yearly expenses would be £382, and the repayment of the loan in 30 years by equal annual instalments would be £136, leaving a balance of £175 to the good. The yearly cost of the sewage purification was put at £150. That included the expenses of two men and a boy. By combining the two schemes his opinion was that they could do with one man less for the electrical station, thereby bringing down the expenses to £100 per year. Those figures were not his own, but those of a practical electrician, and the figures with reference to the sewage were by an engineer. His (the Mayor's) opinion at the present time was that if they combined the two schemes the profit of the one would pay the expenses of the other; even when they were repaying the loan. Then, again, if the private installation exceeded 500 lamps, every lamp they could get out would add to the annual income. He did not ask them to decide upon the sewage or electrical part of the scheme that day, but he thought after giving them those figures he would be justified in asking the Council to form a small committee, not exceeding five members, with authority to spend upon the electrical portion of the scheme, say, £10, for which sum they could get both the opinion of electrical and hydraulic engineers. They would examine the ground, prepare plans, and give an estimate of the cost. They (the Council) could then see if it was practicable, and if so, they would have reliable figures before them, and they could then make up their minds whether they would have it or not. On the proposition of Alderman Hyam, the Mayor was requested to appoint his own committee, and the sum of £10 was voted to them for the purpose mentioned.

PROVISIONAL PATENTS, 1893.

SEPTEMBER 4.

16571. **Improvements in signal, telegraph, or other posts.** Illius Augustus Timmis, 2, Great George-street, Westminster, London.

16594. **Improvements in electrical means of advertising.** Alfred Rene Upward, 150, Holland road, Kensington, London.

16597. **Improved inspissated oil for electrical insulating purposes, and method of producing same.** Adolf Gentzsch, 55, Chancery lane, London.

16630. **Improvements in obtaining zinc from solutions by electro deposition.** Benedict Kitto and William Muir, 30, St. Swithin's-lane, London.

SEPTEMBER 5.

16699. **Improvements in electric cranes.** Walter Pitt, 24, Southampton buildings, Chancery lane, London.

16702. **Improvements in electro-coils for the administration of electricity to human beings, for medical purposes or others.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 43, Cornwall gardens, London.

SEPTEMBER 6.

16746. **Improvements in the design and manufacture of polarisation plates for electric apparatus, and frames or holders for same.** George James Davis Overton, Ormeley road, Balham, London.

16770. **Improvements in electrical connections to floating vessels, balloons, buoys, and the like.** George Morison Hamlyn, 28, Southampton-buildings, Chancery-lane, London.

SEPTEMBER 7.

16836. **Improvements in or appertaining to incandescent electric lamps.** William Phillips Thompson, 6, Lord-street, Liverpool. (Otto Berndt, Germany.)

16851. **Improved insulating material for electrical purposes and method of producing same.** Adolf Gentzsch, 55, Chancery lane, London.

16880. **Improvements relating to the coating of plates, wire, and other metal articles by electro-deposition to protect the same from corrosion, and apparatus therefor.** Sherard Osborn Cowper Coles, 45, Southampton buildings, Chancery lane, London.

SEPTEMBER 8.

16912. **Improvements in electric current meters.** Michael Birt Field, Claremont, Woodberry Down, London.

16923. **Improvements in or relating to means or apparatus for preventing unauthorised persons overhearing private conversations by or through the telephone.** Charles Edward Peniston, 323, High Holborn, London.

SPECIFICATIONS PUBLISHED.

1892.

14533. **Converting alternating currents of electricity into direct currents.** Lucas and New.

15197. **Electrolytic apparatus.** Andreoli.

17423. **Supplying electricity to vehicles.** Chabeault.

18666. **Electrolytic decomposition of compounds of metals and sulphur.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

19242. **Cases for electric batteries, etc.** Oblasser and Théryc.

1893.

4910. **Electric switches.** Joseph.

4911. **Electric lampholders.** Joseph.

4912. **Electric lamps.** Joseph.

9290. **Electrolysis of salt.** Craney.

9965. **Electrically working and welding metals.** Longsdon. (Krupp.)

11579. **Electrically welding metal.** Thompson. (Coffin.)

13489. **Electric bell.** Zeitschel.

NOTES.

Church - Lighting. — The church of St. Botolph, Bishopsgate, is now lighted by electricity.

Tunnel - Lighting.—The recent railway accident in the Box Tunnel suggests the idea of lighting long tunnels by electricity.

The Wembley Tower.—An electric arc lamp or search-light of enormous candle-power is to be erected at the top of this tower.

British Association.—The meeting next year will take place at Ipswich, and the Marquis of Salisbury has been chosen president.

Brighton.—The sea-front was lighted by electricity for the first time on Saturday evening. There are 40 arc lamps of 1,000 c.p. placed at distances of about 40 yards apart.

Italian Electric Tramways.—A company has been formed for the purpose of constructing an electric tramway in Varese, and a similar line is projected between Argegno and Lanzo d'Intelvi.

German Central Station.—The central station at Stettin has a total length of supply mains of about 28 miles wholly composed of Siemens cable, lead covered and wound with iron tape.

The Post Office and the Telephone.—It is stated that the agreement between the Postmaster-General and the telephone company will not be laid on the table of the House of Commons until the autumn sitting.

Travelling Torpedo.—Some experiments with a travelling torpedo have just been carried out at the torpedo station established near Fort Mingam, at Brest. The trial of the new torpedo is said to have been a success.

Railway "Fogging."—The agitation now proceeding among the "foggers" in the Metropolis should tend to induce the railway companies to introduce either a mechanical or electrical system of placing the detonators on the metals.

Conduits.—The catalogue issued by Messrs. Ropkins and Co., Limited, of Wisbech, contains designs of sections of electric cable conduits and examples of mouldings and skirtings worked for electric and telephone wire casings and covers.

Exhibition at Madrid.—A universal exhibition is to be held at Madrid from April to October of next year, one section being devoted to electricity. The English agents for the exhibition are at 21, Great Newport-street, St. Martin's-lane, W.C.

Exhibition at Newcastle.—It is proposed to hold from November 6 to December 2 next, in the St. George's Drill-hall, an industrial, electrical, and general trade manufacturers' exhibition, illustrative of engineering inventions—mining, electrical, etc.

Skeleton Keys Doomed.—An ingenious Frenchman, named Langlassé, has devised a simple arrangement of electrical contacts for door locks which, during the hours when no watch is kept, will give notice by ringing a bell of any attempt at opening the door by means of false keys or pick locks.

Electro-Harmonic Society.—A smoking concert will take place next Friday, the 29th inst., at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., commencing at 8 p.m. There is a strong and attractive programme, and members are invited to turn up in good numbers.

Edinburgh Tramways.—The Corporation are inviting offers for the lease of the tramways, and Mr. Wm. White Millar, of 8, George street, Edinburgh, will supply particulars. We wonder whether there is any chance for electric traction. At any rate, proposals must reach the town clerk on or before the 29th inst.

Cheap Incandescent Lamps.—We are informed that the Edison and Swan United Electric Light Company, Limited, have, from yesterday, reduced the prices of incandescent lamps of standard sizes from 3s. 9d. to 1s. 9d. The excellence of the quality of the lamps will be maintained, and no inferior lamps will be placed on the market by the company.

Search lights.—Some interesting experiments have been made at Lydd in shell firing at night at an object representing a ship rapidly moving across the ranges. The shells were supposed to be fired from a land fort at an enemy's ship at night. For the purpose of discovering the object electric search-lights were used, for which an installation was temporarily put down at the camp.

New Portable Lamp.—At a meeting of the North Staffordshire Mining Institute at Stoke on Monday, Mr. Doubleday read a paper on a portable electric lamp devised by Mr. Sax Sussman. The lamp is 2¾in. square and 8in. high, and its total weight is 3½lb. It gives a steady, clear light, of a power, it is said, superior to the best modern safety oil lamp. It gives a light for 16 hours.

Installation Work.—Before the London Association of Foremen Engineers and Draughtsmen, Mr. W. P. Heath recently read a paper on "Electrical Installation, Wiring, and Fitting." Among other matters, he mentioned that in new buildings intended to be lighted by electricity, architects were now making provision for the wires to be carried down chases in the walls, just as they made provision for drain and other pipes.

Laundry Exhibition.—At the Laundry Exhibition, which closes at the Agricultural Hall to-morrow, Messrs. Crossley Bros. show an "Otto" gas-engine which drives a Crompton dynamo energising four arc lamps. Messrs. Ullathorne and Edmondson, of Bradford, exhibit a dynamo lighting arc and incandescent lamps, and an electric ironing apparatus, the roller being heated by the electric current. Messrs. Glover and Hobson, of St. James's-road, S.E., have on view a new engine, termed the "Williams," and which is described in another column.

Treatment of Sewage.—A new system of treating town sewage is being tested in London, specially with a view of dealing with the drainage of seaside towns. The idea is that of electrically treating sea-water, and thereby effecting such chemical changes as to render it a powerful disinfecting solution. A portable engine is used, the dynamo for supplying the current being bolted to its carriage, and the new disinfectant is pumped into the sewers by the same engine, a hydraulic sewer-flushing apparatus being employed so as to obtain the greatest effect.

Zambesia.—The Portuguese Government has formally confirmed the contract of March 28 last with the Portuguese Companhia Zambesia, conferring upon it exclusive rights for the construction of a network of telegraphs between the Zambesi Tête, Quilimane, Chinde, and other localities. Besides the cable connecting Quilimane and Mozambique, pursuant to Article 11 of the Anglo-Portuguese treaty, the Government is empowered to compel the company to make telegraphic connections across Portuguese territory between the opposite frontiers, reaching the latter from British territory.

Speed of Vessels.—Mr. Edison's latest suggestion concerns the amount of speed lost in a vessel owing to the friction of the water upon her sides. He claims that by

producing hydrogen by electricity along the sides of the ship, which he has tested by a model in a tank to be practicable, he can reduce the friction of the water to a minimum. Unfortunately, when he tried the same experiment in genuine salt water at Sandy Hook the results were not so satisfactory. Another scheme is to force oil of an inferior quality through the pores of the underwater-line plates of a vessel.

Discharging Point of Lightning Protectors.—According to an article written by M. Precht for *Wiedemann's Annalen*, a discharge from lightning protectors is only produced when the potential exceeds 15,000 volts. Extremely fine terminal points have even been charged up to 25,000 volts without obtaining a regular discharge. The presence of dust in large quantities, or of gas round the discharging points, makes the discharge apparently less easy, whilst the concentration of ultra-violet light upon them facilitates it. A group of points can be charged to a higher potential than a single one.

Prize for New Battery.—Sometime ago, *L'Elettricità*—an Italian technical paper published in Milan—offered a prize of 2,000 lira (= £80) for a new electric battery which should fulfil certain conditions. The time during which the competition remained open was twice extended, but definitely closed at the end of last year. It is now announced that the result of the competition has not been in any respect equal to what was hoped: none of the batteries entered for the prize fulfilled all the necessary conditions, and only one—viz., that devised by Prof. R. Rosati, of Florence—comes within the range of honourable mention.

Fire Alarm.—The attention of the Paris Academy of Science has been directed by MM. Delahaye and Boutille to an ingenious application of electricity as a fire alarm. A small ball of aluminium is supported at one end of an arm, with a counterpoise at the other, the apparatus being in equilibrium at any ordinary pressure and temperature of the air. If, however, the specific gravity of the atmosphere of a room is considerably diminished either by a rise of temperature or an admixture of coal gas in sufficient amount to become explosive, the balance is destroyed, and the ball in falling completes an electric circuit by which an alarm bell is set ringing until the normal state of affairs is re-established.

Glasgow and West of Scotland Technical College.—The main objects of this college, the calendar of which for 1893-94 has just been published, are to provide a suitable education for those desiring to qualify for an industrial profession or trade, and to train teachers for technical schools. There are both day and evening classes. In the case of the former, regular courses have been arranged in, among others, civil engineering, mechanical and electrical engineering, naval architecture, mining engineering, mathematics and physics, and chemistry. Similar courses have been organised in the evening classes. The details of each course are contained in the calendar, and any further information may be obtained at the office of the secretary, 38, Bath street, Glasgow.

Institution of Electrical Engineers.—The Council believe that a time must arrive when a benevolent fund in connection with the Institution will be found desirable for the assistance of necessitous members and their families, or the families of deceased members, and they have therefore established such a fund, termed the "Benevolent Fund of the Institution of Electrical Engineers." The fund will be managed and administered on lines similar to those which govern the benevolent fund of the Institution of Civil Engineers. The Council trust that all members will assist the fund personally, and also by using their influence to obtain subscriptions and donations from friends interested in the profession. The secretary of the Institution will be happy to receive subscriptions or donations.

Feed-Water Heaters.—We have received a copy of the new price list issued by Wright's Patent Heater Condenser Company, of 16, Great George-street, Westminster. It is to be noted that the improved Berryman feed-water heater, which is made by the company, has been adopted with satisfactory results by, among others, two or three electric supply companies in the metropolis and by various prominent electrical contractors. By the use of Wright's injector surface condenser and steam-water refrigerator it is claimed that a saving in coal is effected of from 20 to 60 per cent., and in water of from 80 to 90 per cent. A description is given of Wright's compound-cylinder release engine, which is shown coupled direct to a dynamo. The list will be of interest to steam users generally.

German Electrical Engineers.—The Union of German Electrical Engineers, recently formed in Berlin for the purpose of dealing with both commercial and technical matters relating to electrical engineering, will hold their first annual meeting at Cologne between the 27th and the 30th inst. Papers on the following subjects will be read: "Impressions of the Chicago Exhibition and the Electrical Congress," by Dr. Budde; "On a System of Measurements for Central Electric Stations," by Dr. Kallmann; "Charging Accumulators by means of Alternating-Current Machines," by Mr. Pollak; "On the Development of House and Private Telegraphs and Telephones in Connection with the Imperial Post," by Dr. Sack; and "On a New Insulation Testing Set, and an Incandescent Lamp Resistance," by Dr. Heim.

The Glasgow and Belfast Telephone.—Some four months ago, at a cost of about £20,000, the Post Office laid down a telephone between Glasgow and Belfast. The tariff, however, was so high—namely, 5s. for three minutes' conversation—that for two months no business was transacted. The price was then reduced to 3s., or 1s. a minute, and since this reduction, which took place on July 28, there have been six conversations across the wire. One of these extended to nine minutes, thus costing the caller-up 9s. By an arrangement just entered into with the National Telephone Company there are to be increased facilities for telephonic communication between the two commercial capitals, which should lead to extended business. Subscribers can now get switched on to Belfast from their places of business.

Controlling Clocks by Electricity.—Mention was made in a previous issue of a system of controlling clocks by electricity, devised by Herr von Hefner-Alteneck. It consists in simply incorporating the control system with the electric light or power installation already existing by means of a particular form of clock which is placed in circuit like an ordinary incandescent lamp. It is kept wound up by the current at an annual cost not exceeding 9d. for 24 hours, and in the case of interruption of the circuit the clock will, it is said, go for about 12 hours independently of the circuit. The control is effected once a day by a momentary drop of the circuit potential by about from six to ten volts at 5 a.m., which has the effect of setting all the clocks in the circuit at five. The effect on the lamps is inappreciable, and the control can be performed by hand in the dynamo-room or automatically.

Science and Art.—The latest edition of the "Science and Art Directory," just issued by the South Kensington authorities, contains some interesting figures on the progress that is being made in the teaching of science and art. Last

year there were 180,410 pupils under instruction in science, 108,858 of whom were examined, the number of papers worked by them being 203,347, out of which 136,778 were accounted worthy of the "pass," while 35,932 were placed in the first class. These figures show a marked advance on the previous year, the grant from South Kensington being £123,647, in addition to sums granted out of the Imperial subvention of £750,000 under the Local Taxation Act, a large portion of which is now devoted to science and art teaching. Last year South Kensington granted £133,008 to elementary schools in aid of the teaching of drawing, while £56,317 was paid to schools of art. The total expenditure of the Science and Art Department was £635,470, out of which £37,260 was for administrative purposes.

Ocean Telephony.—A paper on this subject was presented by Prof. S. P. Thompson at the recent electrical congress at Chicago. At present, ocean telephony over any considerable distance is impracticable owing to the retardation of the signals, and even rapid automatic sending is out of the question. This retardation of the signals is due to the electrostatic capacity of the cable, which is distributed uniformly along the whole length of the line, and cannot be corrected by compensating devices fitted at the ends of the cable. A distributed remedy is wanted, and this Prof. Thompson proposes to obtain by using electromagnetic induction to correct the retarding effects of the electrostatic capacity of the cable. This he does by constructing the cable on a three-wire system, two of which are to form the complete circuit, whilst the third constitutes an inductive shunt connecting these two wires at intervals. Such a cable would cost considerably more to construct than an ordinary cable, but Prof. Thompson claims that it would do 10 times as much work.

Decimal Weights and Measures.—At the Engineering Congress held at Chicago on August 1, and which was attended by leading members of the profession from many countries, a paper on the fundamental units of measure was read by Mr. T. C. Mendenhall, superintendent of the United States Coast and Geodetic Survey, as well as superintendent of the standard weights and measures at Washington. Mr. Mendenhall stated, *inter alia*, that the office of weights and measures at Washington, with the approval of the Secretary of the Treasury, would in the future regard the international prototype metre and kilogram as fundamental standards; and the customary units, the yard and the pound, would, as from April 5, 1893, be treated as derived therefrom. This amounts to an official notification that the United States have formally adopted the metre as the standard of measurement. In future the yard will be represented as a fraction of the metre, and the pound as a fraction of the kilogram, in the Washington Office of Weights and Measures. This is a great step towards the introduction of the metric system in the United States.

Electricity in Military Operations.—An interesting night attack, devised by and carried out under the superintendence of Major-General Geary, R.A., was made at Portsmouth on Wednesday evening. Besides the primary object, which was to determine how far the electric light of shore defences is efficient for the lighting up of vessels attempting to approach the harbour, the affair had something of the nature of a surprise, and was intended to test the mobilisation scheme for the defence of the eastern entrance to Spithead. The field of operation extended on the north from the Warner light-vessel to Fort Cumberland, and thence along the coast to Fort Gilkicker, and on the south from the Warner along the shore of the Isle of Wight as far as Ryde. The operations were appointed to take place at about eight o'clock, but it was not until close upon nine that the firing of a rocket announced the beginning of the attack. The fight continued until ten o'clock, when the flashing of the search-lights skyward conveyed the order to the troops to return to barracks. As far as observation went, remarks a correspondent, the electric lights appeared too feeble for the purposes contemplated.

Gas and Electric Light.—Mr. E. C. Riley, president of the South West of England District Association of Gas Managers, remarked last week, at a meeting of the society at Exmouth, that the two great rivals recognised by them were first petroleum, and, secondly, the electric light. He illustrated this, in the case of electricity, by stating that a large company having a private works for their own gas supply obtained a fine installation of the electric light; with the result that the quantity of gas required from their own works was reduced by from one-third to one-half. But since the completion of the installation, from various sources—such as the extended use of gas for special industrial processes, and to avoid the cost of the provision of day current, when the work on the dynamos would be so unprofitably light—the consumption of gas had quietly and steadily grown, so as to have nearly attained the same figure as before the electric light was introduced. It appeared to him that the moral of this illustration was that gas managers should take every opportunity of showing the real value and usefulness of gas, and that special efforts should be made to adapt its use to special purposes. This view of the matter is certainly very sensible.

Poor Light.—The hotel proprietors and restaurant keepers of Avignon, says *Electricité*, have sent in a petition to the Municipal Council of that city, wherein they allege a serious falling off in the candle power of their electric lights, and ask that the authorities shall intervene in order to ascertain whether the lighting power given by the lamps furnished by the electric lighting company is in accordance with the undertaking entered into with each subscriber. It is more than doubtful whether the authorities will take any action in the matter, as they practically are unable to do so; they have merely given to the company a right of way, and that is all. The lesson to be learnt from such a dispute is that contracts to supply so many lights at a fixed rate for a given candle-power are most unsatisfactory in daily work, and no system of this kind can supersede in excellence or be fairer than the use of meters. In regard to defective pressure, it would seem, however, to be essentially the part of public authorities who have rights to give electric lighting companies to secure a reasonable service from the latter, and any excessive variation of pressure in the public supply ought, as a primary condition, to be forbidden. The local newspaper press claims, however, that the town-lighting leaves nothing to be desired.

Ediswan Portable Batteries.—A large variety of portable secondary batteries for different purposes is being manufactured by the Edison and Swan United Electric Light Company, Limited. The batteries are made in various sizes to suit particular requirements. For instance, the A type is the smallest size made, comprising two cells suitable for placing in the pocket to energise lamps arranged in scarf pins, head dresses, jewellery, flowers, etc., and intended specially for theatrical and music-hall use, and for surgical and dental work. A light of from two and a half to three hours per charge can be obtained with these batteries by the use of lamps of about 3·7 volts. The B type of battery is intended for similar purposes; it is larger and yields per charge a light for five hours. For the illumination of railway carriages and tramcars the C type has been designed, and by combining two, three, or more, batteries of any re-

quired power may be obtained. Batteries of this kind are also made to meet the requirements of medical men. A convenient form of hand lamp capable of extensive employment is provided by the D type of battery and lamp. It weighs 7lb., and gives a light of 1 c.p. for 10 hours. Full particulars and illustrations of these batteries are given in the company's new catalogue, Section 6, which has just been issued. In addition, the list contains instructions for the charging of the batteries, etc., together with prices.

Alternating Currents of Constant Frequency. A recent issue of the *American Journal of Science* contains a paper by M. J. Pupin, describing a method of obtaining alternating currents of constant and easily-determined frequency. For this purpose he uses a small transformer whose primary circuit contains an interrupter of peculiar design. This consists of a stiff brass wire, stretched between the pole-pieces of two permanent horseshoe magnets, and carrying at its middle point a short amalgamated copper wire. At every vibration this copper wire dips into a mercury-cup and closes the circuit of a battery; the repulsion between the current in the wire and the magnets serving to keep up the vibrations. The tension, which can be adjusted without stopping the vibrations, is altered until the wire is in unison with a tuning-fork of known pitch. In order to diminish the intensity of the harmonics which are present when the current is interrupted in this way, the primary of the transformer is joined in series with another coil having a movable iron core, and in parallel with a condenser of variable capacity. The capacity and self-induction of the circuit are by these means altered till the natural period of the circuit corresponds with the fundamental of the wire. The attainment of this condition is shown by the sparking at the break being a minimum. Under these circumstances the circuits acts as a resonator, and selects from the complex E.M.F. that harmonic with which it is in resonance, and strengthens it.

Electric Light Letters for Advertising.—An important advertising novelty is now being introduced in London in the shape of electric letters formed of bright plated metal backing, of hollow section, mounted on a board to any possible design. Into these backings glass tubes of uniform diameter and various lengths, enclosing a filament, are fitted. The tubes are joined in circuit, without any artificial resistance being used, so that the electric light letters are joined direct to the lighting-main as if they were ordinary incandescent lamps. The appearance of the electric light advertisements or signs, etc., formed of these letters, which are of particularly attractive and tasteful design, is of so unusual and striking a character that they form a most powerful means of arresting and sustaining the attention of the public. These electric light advertisements can be arranged to switch themselves on at dusk and off at daylight. The letters and signs, which are made complete, and are mounted ready for erection, by the Edison and Swan United Electric Light Company, Limited, at their Ponder's End works, are specially suited for theatres, railway stations, exhibitions, restaurants, hotels, shops, for advertisements in tunnels, underground railways, and every other place where an ordinary advertisement would be useless. Attention is particularly drawn to one out of numberless effective applications to which these signs can be adapted—namely, for shop fronts, the name of the proprietor being formed by these electric light letters mounted on a skeleton frame suspended in the window, affording a brilliant advertisement and a brilliant light, thus rendering any other form of window-lighting unnecessary. We understand that the Electrical Advertising Syndicate, Limited, are the proprietors of the invention, and are already erecting these signs in London The sign "Partington," shown in Charing Cross underground railway station, is an example of the most recent type of letter. The letters in question have been designed by Mr. Réné Upward, who is consulting engineer to the syndicate

High-Frequency Discharges.—We have received a copy of a reprint of an article in the September issue of the *Philosophical Magazine* on "Experiments with High-Frequency Discharges," by Mr. A. A. C. Swinton. The author, by employing the apparatus described in that magazine for February, 1893, for producing electric discharges of high potential and high frequency, has obtained several curious effects. A flat tin dish filled to a depth of about ½in. with rosin oil was electrically connected to one terminal of the high-frequency coil, and a wire connected to the other terminal of the coil was suspended with its extremity about 3in. or 4in. above the surface of the oil in the dish. On putting the coil in action, the oil was immediately thrown into a state of violent agitation, the whole surface bubbling and foaming, while the oil gradually crept up the inclined sides of the dish in a well-defined wave, and finally overflowed. The effect appears to be due in great measure to the violent repulsion of the particles of air from the suspended wire into the oil. A similar result was obtained when alcohol was substituted for oil in the dish, but the alcohol immediately caught fire. With ordinary paraffin oil the effect was the same and the oil caught fire, but only continued to burn so long as the electric discharge which supplied the additional heat necessary to keep the oil burning was maintained. Distilled water was next tried, but with this no agitation of the surface or creeping-up of the liquid ensued. When, however, the suspended wire was lowered so as to touch the surface of the water, an octopus-like figure of bright sparks, about 2in. to 3in. in diameter, was formed on the surface of the water, and even when the wire was further lowered so as to dip three-eighths of an inch into the water, so that the point of the wire was within one-eighth of an inch of the tin dish, the sparks still spread out, leaving the wire at its intersection with the surface of the water, and not at the point of the wire, which, as already mentioned, was within one-eighth of an inch of the tin dish. In fact, it was not until the point of the wire and the dish were brought very nearly into contact that the discharge took place through the water, which it then did with very white sparks producing small explosions, and the sparks on the surface ceased.

The Government and Telephony.—On the resolution for the post office and telegraph service on Tuesday evening, Mr. Henniker Heaton said that a grosser blunder had never been committed than for the Post Office to keep in their own hands the unproductive trunk telephone lines while they have left the paying local lines in the hands of the private companies. Sir A. Rollit spoke of the great interest which the municipalities had shown in the telephone, and considered that what was now proposed was not a restriction upon municipal action. It was not correct to say that the charge for the telephone was £20. When all the circumstances were taken into account he found that the average charge in London was £15, and in the provinces £8. 16s. He would not express an opinion as to whether a lower price would pay. His view was that the work should be done in the best form, in the belief that really good public service would in the end be most remunerative. The administration of the Department in this matter, both by the Postmaster-General and by his predecessor, had been such as to lead the company to desire nothing that was not fair and reasonable. Their desire was to consult the public

interests, and he could assure the right hon. gentleman that in the negotiations in regard to the agreement they would do their best with him to arrive at a right and fair conclusion. Mr. A. C. Morton said, in his view the telephone companies wanted what was unfair and unreasonable. Their object was to secure by the aid of the Government a permanent monopoly. All he wished to say now was that the Act of last year was rushed through the House in a great hurry. He did not object to the Government purchasing the main lines, but he trusted that the Postmaster General would do nothing to assist a monopoly. Mr. A. Morley, in reply, said he did not think he could be fairly called upon to make a declaration at the present time as to the policy of the Government with respect to the telephones. New developments which had recently come to the front would have to be carefully considered. One of the most important recommendations of the Joint Committee was that telephone companies licensed by the Post Office should have statutory powers for obtaining way-leaves and underground means for laying their wires. He thought, however, that those powers ought to be subject, as they were now, to the assent of the local authorities, which had control over the thoroughfares of our great towns and municipal areas. With regard to the agreement between the Post Office and the National Telephone Company, the heads of which were drawn up by the late Government, he remarked that a very strong case would have to be made out that would justify the House in departing from the terms of the agreement.

Death by Lightning in France.—According to statistics, the average number of deaths caused by lightning in France between 1835 and 1883 amounted to 100 annually. From one year to another, however, the number of victims is very variable. The number of those struck, but not fatally, is about five times greater on an average than those killed outright. The year 1890 was exceptional for the frequency and violence of its thunderstorms, and the number of persons struck, as well as of persons killed, shows a like increase. The effects of the "thunderbolt," as it is popularly called, are variable, according as the person is struck directly or by *contre-coup*. The lesions *en évidence*, remarks the *Lancet*, take the form of burns or lacerations, insufficient by themselves to account for death, which is sometimes instantaneous, and is sometimes preceded by an agony more or less prolonged. Pathology has not said the last word as to how death is caused. Some French physicians ascribe it to "cerebral perturbation which paralyses the bulb"; others to "electrolytic decomposition of the tissues and the liquids"; and others, again, to the "evolution of a gas in the vessels of the circulation." The bodies of persons struck by lightning present phenomena quite fantastic, in their form especially. On some, the scorching assumes an almost artistic configuration, insomuch that more than one observer has traced these "designs" or "lightning drawings" not to chance, but to the "outlines of objects that happen to be in the immediate neighbourhood of the victim when struck by the thunderbolt"—the phenomenon being one of "reproduction or transference." Sometimes these figurings assume arborescent or tree-like forms. If death is not instantaneous the effects are very variable, according to the constitution or state of health of the individual, or according to the circumstances in which the visitation occurs. Dr Nothnagel, professor of clinical medicine in the Vienna School, has made a special study of "stroke by lightning," and has reproduced the phenomenon in question on rabbits by means of a Leyden jar. In a recent lecture he described the non-characteristic of the external manifestations of the person struck and also the first steps that should be taken for his recovery. His observations have special interest as regards the effect of the "stroke" on the brain, on the spinal marrow, and on the peripheral nerves, particularly as to loss of consciousness, cerebral disturbances, and ataxic complications. Shock to the visual organs and partial paralysis of the tongue—this latter being sometimes peculiarly unresponsive to treatment—were amongst the symptoms more distinctively characteristic of the lesion; others, again, bore an affinity to the nervous perturbations induced by railway collisions or by accidents which affect violently and suddenly the mental or emotional faculties.

The Fatal Accident.—The enquiry held on the 15th inst. with reference to the death of Mr. W. Ball at the Blackfriars transformer station, and which was dealt with in our last issue, has been adjourned for three weeks to allow of the attendance of the assistant Meech, who was injured at the same time. Mr. A. C. Langham, deputy coroner for Southwark, conducted the enquiry, and Major P. Cardew represented the Board of Trade. Philip Hunt stated that on Tuesday evening, about half past six o'clock, he was called into the provider-house of the London Electric Supply Corporation, where he found the deceased lying on the floor between two converters and a stool. He appeared to be dead. A young man named Meech was at the door, very badly burned. The witness at once telephoned to one of the other stations for assistance. Meech, when he saw witness, said that whilst he was dusting down they had turned the main on, but witness found that that was not the case, as on looking up he found that the switch gear was down. Witness was not employed by the corporation, but he worked on the same premises. He thought that if they had turned on the switch they would have first telephoned through from Deptford. J. G. Freeman, the engineer in charge of the London Electric Supply Corporation's station at Blackfriars, stated that on receiving the telephone message for help he at once took a cab, and arrived at the Blackfriars station shortly after 7 o'clock. Meech, the assistant lineman, was sitting on a stool, whilst Ball was lying on the ground dead, with outstretched arms, near to transformer 42. Looking round to discover how the deceased might have received a shock, he found a duster lying on the terminal of the transformer. Witness was of opinion that the deceased had received the shock from the omnibus bar whilst engaged in dusting. The deceased had been in the Corporation's employment for a number of years. He was always a very careful man, and must have been aware of the danger he incurred when dusting with the plug in the omnibus bar. The deceased was the only person to blame in the matter. Mr. P. W. D'Alton, engineer-in-chief to the London Electric Supply Corporation, said the deceased had the reputation of being an exceptionally careful, trustworthy man, and that he knew every bolt in the building. It had been a piece of lamentable forgetfulness on his part not to have removed the plug before commencing to dust. Meech's duty required no previous knowledge of electricity. Notices with "Dangerous" on them were posted over the machinery. Dr. Hamilton, house surgeon at Guy's Hospital, said he saw the deceased between seven and eight on the Tuesday evening. There was a ragged wound on the back of his right wrist and hand, and the flesh was charred and smelt of burning. There was also a smaller wound on the back of the left wrist, and the injuries had the appearance of having been caused through contact with electricity. Other evid[illegible] showed that Meech had been badly burn[illegible] enquiry was adjourned, as mentione[illegible] attendance.

ELECTRIC SUPPLY COMPANIES.—I.

The world electrical moves fast, not so fast in some directions as electrical engineers and the world in general would doubtless like, for electric traction still lags, and the telephone, though with us, is not yet for us in the way we would desire. Nevertheless, it moves, this world of matters electrical, and those in it and of it, while pushing their hardest at the great fly wheel of applied science, sometimes see only the increased activity in their own corner, and wonder how matters are really progressing among their fellow-compeers. Another season is upon us, and after the outward movement of individuals on their holidays, abroad, or even to Chicago, the reconcentration will commence upon the serious work of the season, plans are laid for future extensions, papers will be read, new developments, new inventions brought forward and discussed, and so the progress of electrical engineering goes on. How has it gone during the last year or two amongst the large concerns—electric lighting companies and their stations especially? This is a question many will be asking, and a question we shall attempt, in some sort, to answer. From the period of tentative, of trial, sometimes of surprise, has succeeded a period of certainty and of knowledge of results. Station engineers, consulting engineers, contracting engineers, upon whom the chief work of organising and running enterprises of great pith and moment depends, now know where they stand and in what direction to look. It will therefore be interesting to glance around and make an up-to-date report upon the stations now supplying the Metropolis and other large towns in Great Britain, to see exactly in what position they now stand, their progress, their results, their hopes and fears. Useful, too, in a way every practical man will understand, will be to see exactly how their organisation, their machinery are working—what are found good, and in what directions modifications are or might be made; what details have stood the test of time, or what have been discarded. And the great question of cost of generation—how is this supervised and dealt with on a commercial basis, what results are achieved, and what may be looked for in the future? In giving a description of the present status of the great electric light companies now at work from this point of view we shall, we think, be giving not only a useful comparison of work accomplished, but an interesting summary, profitable alike to practising engineers, to students, and to intending customers—be they private or public corporations.

Our purpose is briefly to deal with the history during the last year or two of these undertakings, to describe with some technical detail the plant and working of the stations, and to deal in general with the cost of generation and distribution of electrical current to the public. We shall begin with the Westminster Electric Supply Corporation, a company interesting and important alike for the central position it occupies, for the fact that it supplies our Houses of Parliament, and for the care with which every detail of working and management has been thought out under the guidance of their able chief engineer, Prof. Alexander B. W. Kennedy, F.R.S., whose devotion to the cause of electrical engineering is indefatigable.

THE WESTMINSTER COMPANY—GENERAL.

The Westminster Electric Supply Corporation, Limited, was registered on 30th June, 1888, with a capital of £100,000 in 20,000 £5 shares. This has been subsequently increased to £300,000 in 60,000 £5 shares, which are all fully paid up. These shares are now officially quoted at 5¾, but are held tightly, and any transfers that are made at this moment are made at but little under 6, which sufficiently indicates the status of the company at the present date. In addition to the ordinary share capital the company have issued debentures to the extent of £29,400 at 5 per cent., and owing to the advance of the company the next issue of £40,600 of debentures was made at 4½ per cent. (making a total of £70,000), and it is quite expected that any further issue will be able to be made at the very moderate price of 4 per cent.

The Westminster Company obtained their provisional order in 1889, and commenced supply from a temporary station in Dacre-street, Westminster, on July 1, 1891. Their standard charge at the commencement was at 8d. per Board of Trade unit.

The company then obtained permanent sites, and erected three stations: (1) at Millbank-street, Westminster; (2) at Eccleston-place, Belgravia; (3) at Davies street, Mayfair. Their chief office was for some time at Victoria-mansions, but this has now been removed to their Eccleston place station, where the staff occupy a fine set of specially-built offices adjoining the central station.

The charge for current was reduced on July 1, 1892, to 7d. per unit, and still further on April 1, 1893, to 6d. per unit for electric lighting, while current for motor purposes is being supplied at 5d. per unit.

The system employed throughout is the low-tension continuous-current system, at 100 volts, with three-wire distribution, using accumulators in conjunction with direct supply. All the three networks are connected together in parallel, though means are adopted for working separately when desired, or for one station to take the load or part of the load of any other station if necessary.

In February last the total amount of roadway laid with mains was 33 miles, making 130 miles of ways, into which upwards of 97 miles of copper strip and cable had been drawn.

The current being supplied at the various dates as below was as follows, in the equivalent of 8-c.p. lamps:

Dec. 31, 1891,	current equivalent to	62,820 8-c.p. lamps.
Dec. 31, 1892,	" "	98,686 "
July 31, 1893,	" "	114,294 "

On the latter date there were applications in hand for about 6,000 more 8-c.p. lamps, making, therefore, a total of 120,000 8-c.p. lamps.

The company have lately been endeavouring to get their customers to take current for electric motors, and already have met with very satisfactory responses, and this department of supply seems likely to grow to considerable dimensions. Already several electric lifts have been installed, in addition to a fair number of motors for ventilating and driving purposes. These motors in every case are supplied direct from the lighting mains. At first there was some difficulty owing to the large and sudden increase or decrease in current taken; but a rule has been made that in every case a starting resistance must be inserted, and they have succeeded in obviating all difficulty from fluctuation of voltage. The same observation applies to the supply of large arc lamps for photographing, of which several are now supplied.

The company have machinery capable of supplying an equivalent to 130,000 8-c.p. lamps. With additional plant, for which room has been left, this can easily be extended to supply 170,000 lamps, while with the addition and extension of the premises on the present sites plant equal to the supply of 600,000 such lamps can be installed. It is not thought that an addition to the number of stations will be necessary to cover the district over which the company have powers of supply.

The Westminster Company paid their first dividend as an interim dividend of 3 per cent. on June 30, 1892, for the half-year. On December 31, 1892, they paid an additional dividend of 4 per cent., making a total dividend for the year of 3½ per cent. per annum. An interim dividend has now been declared for the half-year ending June 30, 1893, of 3 per cent.

Almost from the commencement the company supplied the electric light for the Houses of Parliament. This was a partial installation, and it has been further increased by a large number of lights in both Houses, and a further increase in the number of lights will shortly be made. They have made provision for lighting the Foreign Office, and have also been requested to make provision for the supply of other large Government departments.

Among other large buildings and institutions that the company supply may be mentioned Buckingham Palace, the Royal Institution, the Zoological Institution, the Royal Institute of British Architects, the three engineering institutions (the Institution of Civil Engineers, of Mechanical Engineers, and our own Institution of Electrical Engineers). There are also the Westminster Town Hall, the Middlesex

County Council, the Cape Government Office, the New Zealand Government Office, and the General Medical Council. Of hotels there are the Westminster Palace, the Windsor, Albemarle, Berkeley, Belgravia, Harvey's, and others. Of clubs in the district, they supply the Junior Constitutional, Devonshire, Brooks's, the New University, Badminton, Wellington, Cavalry, Piccadilly Club, Albemarle Club, the Arts Club, etc. Several large photgraphers are also supplied, such as W. and D. Downey, Mayall's, A. J. Langton.

With regard to the supply of large premises, the Westminster make a considerable reduction in price on large supply. It is interesting to note here that the Westminster Corporation were the first company to make a reduction in price to their customers of this kind. The following is their scale of rebates:

Units.		Rebate per cent.	Approximate equivalent in pence per unit.
Under	3,000		6d
Over	3,000	1	—
"	4,000	2	—
"	5,100	3	—
"	6,300	4	5¾d.
"	7,700	5	—
"	9,300	6	—
"	11,200	7	—
"	13,400	8	5½d.
"	15,800	9	—
"	18,500	10	—
"	21,700	11	—
"	25,400	12	5¼d.
"	30,000	13	—
"	36,200	14	—
"	45,000	15	—
"	60,000	16	5d.

Motors are supplied by separate meters at the price of 5d. per unit. The following list of motors already supplied will be found interesting:

Lifts, passenger and service	5
Hairdressing	3
Bottle washing	1
Ventilation	2
Hydraulic pump	1
Circular saw	2
Organ-blowing	2
Dentist drills	6
Lathes, etc.	3
Refrigerator machine	1
Driving testing dynamo	1

Besides this there are supplied:

Cautery instruments	4
Supply for surgery	2
Electric launch station	1
Omnibus charging station (Bristöl Company)	1
Accumulator charging (Lithanode Company)	1

The price for charging accumulators is 5d. per unit. Current for cooking and heating apparatus is also supplied, but not as yet to any very large extent. An exhibition of electric cooking utensils is kept on view, as well as samples of motors, fans, radiators, etc., at the company's offices at Eccleston-place, and these, being shown in action, have been instrumental in inducing several consumers to use electric energy for purposes other than lighting.

The following is a list of the officials of the Westminster Electric Light Corporation:

Directors.—Right Hon. Lord Suffield, K.C.B. (chairman), Sir Douglas Galton, K.C.B., Edmund Boulnois, Esq., M.P., W. Hayes Fisher, Esq., M.P., J. Browne Martin, Esq., J. Heslop Powell, Esq., R. W. Wallace, Esq.

Officers.—Captain Edmund Bax, manager; Prof. A. B. W. Kennedy, engineer-in-chief; Frank Iago, Esq., secretary.

Engineers.—Davies-street: first, Ll. Foster; second, H. H. S. Baker; third, G. Horley; 18 men and office boy. Eccleston-place: first, C. O. Grimshaw, second, F. A. Nixon; third, W. Thompson; 19 men and office boy. Millbank-street: first, F. Newington; second, W. Robinson; third, G. Clarke; 19 men and charwomen.

Mains Department.—E. W. Monkhouse, superintendent of mains; C. Monson, assistant superintendent of mains; J. Turner, clerk; and 33 workmen.

Meter Department (Outside).—L. H. Hordern, superintendent of meters; J. E. Dane, chief inspector; C. G. King, clerk; H. J. White, clerk; Corry, Allard, and Day, meter readers; and three men and one boy.

Meter Department (Inside).—J. W. Jones, chief; A. Mears, clockmaker; W. J. Dawson, assistant clockmaker; also one man and two boys. In this department all meters are tested, calibrated, repaired, etc., and they are delivered to the outside meter department, who fix them in consumers' houses, calibrate them *in situ*, take readings, etc.

Office.—H. Booth, collector; S. H. Stanley, assistant collector; W. A. Pearman, bookkeeper; A. Farthing, transfer clerk; A. E. Upsdell, correspondence, etc.; P. Porter, general, C. Frost, office, C. Weiss, draughtsman, Captain Webb, canvasser.

THE COST OF ENERGY FOR ELECTRIC TRAMWAYS.

BY FRANK B. LEA.

It is considered by many of those who should be in a position to judge accurately the probable course of events, that some reasonable progress in the development of electric traction will soon be made in this country; if for no other reason, this is thought likely because a Joint Parliamentary Committee has put an end to some of the difficulties in the road by drafting model clauses of an equitable nature—protecting all the interests involved—for insertion in tramway and other such measures brought before Parliament. Although such progress must from its very nature be somewhat slow, no great regret need be felt at this, for if we are to take fresh steps in a new direction, they cannot well be too sure. What is vulgarly called a "boom" has, as a rule, but one ending, and the spelling of it is "panic." A steady growth and development is not only cheaper in the end, but offers greater advantages in every way: the experience gained is more reliable than when a mad rush takes place, whilst public confidence is secured with far more certainty. It is most sincerely to be hoped that any progress which may occur in electric traction generally will be characterised by such a steady growth as can alone make of it an enduring and profitable business.

One particularly important point which will require some consideration at the hands of all electric railway or tramway engineers involves the question of stationary power plant, and the cheapest method of obtaining a constant supply of electric energy. The question becomes practically the following: Is it more economical for an electric line to instal its own stationary generating plant, or may it with greater advantage obtain a supply of energy from the nearest continuous-current electric lighting station? assuming, of course, that such may be available—by no means a remote contingency nowadays. So far as electric lighting interests are concerned, the utilisation of their generating plant during the day is of course a most desirable object to attain; every electrical engineer is familiar with the 6 to 10 p.m. "peak" in the output diagram of a lighting station, but the problem of equalising the load throughout the 24 hours in order to have a continuous peak, or rather "tableland," and thus run the station at maximum output, remains as yet practically unsolved. If the average load in such a station were anything like 50 per cent. of the maximum, the selling price of surplus electric energy could without doubt be materially reduced below the 3d. per unit at which it is now offered for such purposes as the working of electric motors, etc., during the day.

Electric lighting authorities in general—whenever a suitable supply is close at hand—would therefore appear likely to show a most favourable consideration of any proposals to sell current for an electric tramway; although the demands from both lighting and power circuits to some extent overlap, say, between the hours of 6 and 10 yet there is usually an ample reserve at all

allow of slight overloading for this period. Such a course is obviously more economical than the running of large machinery during the daylight hours on a small load, or no load at all. Much depends in this connection upon the sizes of unit adopted: the tendency, however, seems to be towards increasing these as much as possible, consistent with economical working

Some figures were given a year or two ago in the American technical papers relative to the cost per car mile of electric energy put into the line, in the case of tramways operated on the overhead wire or "trolley" principle, where the supply was in each case obtained from a station specially erected for the purpose, and there seems to be no reason for doubting their accuracy. The average cost upon 22 such lines was stated to be equivalent to 1·17d. per car mile, the highest being 2·9d. and the lowest ½d. The expenses included were the following: maintenance of power plant, repairs to engines and dynamos, fuel, wages, oil and waste, etc.; but a very essential feature to point out is that the number of cars operated on each line varied enormously—from three to one hundred and forty. It need hardly be said that, as a rule, with the former expenses were naturally at a maximum per car mile, and conversely. The average cost would probably apply to those roads upon which 20 cars or more were running continuously.

It is not, however, at all clear whether any account whatever has been taken of charges which ought, in all fairness, to be included in such estimates, as part of the cost per car mile not incurred on the alternative plan; a sinking fund should be allowed for, and the subject of depreciation is hardly settled by vaguely referring to "maintenance of power plant." Take, for instance, the case of a road upon which 20 cars are kept running over a length of, say, a dozen miles. The capital outlay required for buildings, generating plant, and machinery, etc., would be little, if any, less than £18,000, and a fair amount for depreciation and amortisation of this sum ought to be included.

Returning now to the plan of purchasing electric energy for traction purposes from an electric lighting station, it is obvious that some considerable difficulty must arise in obtaining the average cost, and even in estimating a maximum or minimum. The figures will vary for each individual road, perhaps more especially in proportion to the average number of cars at work, but the questions of speed, length of line, gradient, and loads—both dead and paying weights—also influence the cost per car mile very considerably. The average horse-power required from the supply station or electric mains per car on the line varies, of course, from zero, if the car is supposed to run down hill, to 3 or so when on the level, and to as much as 20 or even 30 when starting with a heavy load on an up grade. Probably 10 h.p. represents the maximum average amount required per car, taking all conditions into account, and many skilled engineers consider that this allowance is excessive.

If we assume, say, 7 h.p. per car, employed for 12 hours daily, with a total of 20 cars on the line, the horse power hours become 1,680 per diem. The car mileage will not exceed 2,000 per day at the outside, but with this allowance, and assuming the price of electric energy to be 3d. per unit, the cost per car mile works out to 1·879d.—a very favourable showing, if the figures upon which it is based are correct. Probably it is too favourable, even with the comparatively large number of cars assumed, and a sum of 2·5d. or even 3d. per car mile would more nearly represent the true expenditure.

In any case the cost of purchasing current from electric light stations for tramway lines would appear to exceed that incurred by putting down special plant for the purpose, not, however, taking into account the trouble and expense of erecting and administering it.

The other side of the question—viz., the advisability of selling whatever spare power there may be in an electric tramway generating station for lighting purposes outside—opens up rather too wide a field for discussion in this place, and it may therefore be fitly taken up at some other time. Meanwhile let us hope that sufficient work may soon be *done to verify or contradict the figures* given herein.

A NEW SHUNT ARC LAMP.*

The fundamental idea of the type of lamp illustrated consists in the provision in shunt to the terminals of the lamp of an electromagnet with a movable armature in connection with a check contrivance, as a clock train, and which forms the arc and also regulates the position of the carbons. Lamps constructed on this principle, although the electromagnetic disposition is the most simple, have certain defects in construction which require special remedies. The first defect lies in the fact that the armature, *b*, Fig. 1, which during the burning of the lamp takes up the position of equilibrium between magnetic attraction and pulling power of the spring, *c* (this position being necessitated by the terminal pressure), is partly dependent upon the weight of the carbons suspended from the holders. As this unequal weight under the thicker upper carbon is continually being altered by the burning of the carbons, the armature must also alter its position, and the tension of the arc change correspondingly with the burning, and certainly increase if the swinging axis of the armature lever falls together with the revolving axis of the chain pulley.

A second defect is based on the known fact that an electromagnet, through heating of the coils, has a higher electrical resistance, and therefore with a constant terminal

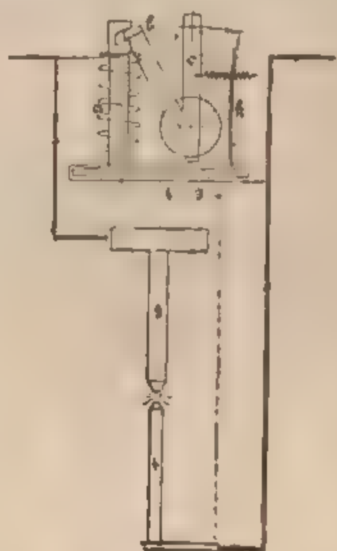

FIG. 1.

pressure its attractive power is weakened. It therefore requires a higher tension than the initial pressure to let the armature play on the same limits with warm coils as when the latter are cold. Nearly all shunt arc lamps of this type are subject to this defect of an increase in the pressure of the arc in consequence of the heating of the coils.

The increase in the pressure through a diminution in the weight of the carbons has in the before-mentioned type been compensated by a lever arrangement, as shown in Fig. 2. As will be seen, the armature lever is connected fast to the clockwork, and the whole system swings round the turning point of the armature lever, whereby the chain pulley must act to the armature lever as an unequal-armed lever in the ratio of 4 to 9. This ratio corresponds to the relation of weight of the carbons to one another, and thus the products from lever length and weight of carbons are equal. As the carbons are now of equal length, and burn equally, it is clear that the equilibrium of the armature lever load during the whole period of burning cannot be interrupted.

The increased pressure of the arc due to the heating of the coils is balanced by a compensation band, *k*. This consists of two pieces of metal soldered together, as, for instance, steel and zinc, and which in a normally cool condition are stretched straight out, and when warm they become curved. As the lower end of this band is firmly fixed by screws, the

* Abstracted from the *Elektrotechnische Zeitschrift*.

upper end, which carries the striking tongue, *g*, must make a certain stroke. The length of the stroke corresponds as far as possible exactly with the recedence of the armature, *b* (caused by the heating of the coils) from its starting point, with cold coils, so that the relative position of the armature remains unchanged, and therefore the pressure of the arc does not vary.

We will now proceed to explain the method of construction. The magnet, *a*, Fig. 2, attracts its armature into a visible slit in the pole pieces away from the spring, *e*. Over the pulley, *d*, of the clockwork, *c*, is laid a chain which carries both movable carbon-holders. If the lamp is put in circuit before the carbons are a specified distance apart, the armature, *b*, lies entirely in the slit, and the stoppage of the clock train by means of the wheel, *f*, and striking tongue, *g*, is removed, so that the carbons in consequence of the greater weight of the upper carbon-holder approach one another. On the carbons coming into contact the magnet, *a*, is suddenly without current, and it lets the armature travel so that the arc is formed, as the chain

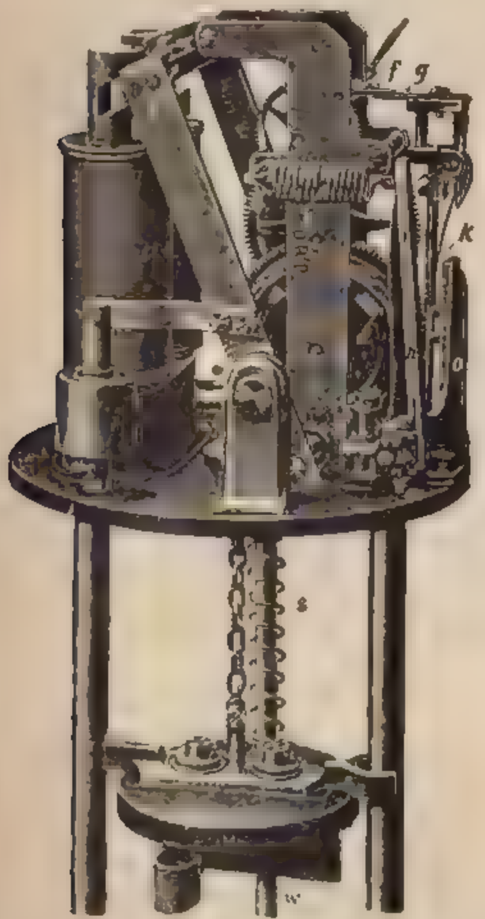

FIG. 2.

wheel, *d*, participates in the movement of the armature lever, and the armature takes up the position of equilibrium between magnetic attraction and pulling power of the spring, *e*.

The approach of the carbons is regulated in such a manner that the armature, *b*, at maximum pressure of the arc is drawn so far into the slot that the wheel, *f*, lifts itself off the striking tongue, *g*, whereby the clock train permits of a slow approach of the carbons, which at the next minute is checked by the stoppage of the flywheel. The regulation of the pressure of the arc is effected by the spring, *e*, which by means of the lever, *h*, is placed in position through the screw, *m*. The current is led to the upper carbon-holder by a movable bare copper spiral, *s*, which is prevented from lateral motion by the rod, *w*.

The chief advantages claimed for this lamp for practical use are great simplicity of regulating the current to a certain pressure. The lamps work well at low pressure, as, for instance, 100 volts, and they are almost independent of the current strength. The lamps are made by Messrs. Korting and Mathiesen, of Leipzig.

RELATIVE COST OF CONDUCTORS WITH DIFFERENT SYSTEMS OF ELECTRIC POWER TRANSMISSION.*

BY GISBERT KAPP.

It is just 20 years ago that the reversibility of the dynamo-electric machine was discovered, and with it the electrical transmission of electrical power. The machines then and until recently employed were of the continuous-current type, but within the last few years transmission of power by some form of alternating current apparatus has come into use, chiefly because it enables us to carry power to a greater distance with a moderate rate, and, therefore, moderate cost of conductors. The reason for this economy lies in the fact that owing to the scheme of commutators, and the facility and certainty with which alternating-current transformers can be insulated, the effective pressure at which the current is transmitted is much greater with alternating than with continuous currents. To put it in another way, with continuous-current plant the voltage is limited by the difficulty of insulating the generating and receiving machinery. With alternating-current plant there is no necessity of high insulation of generators or motors, but only of the step-up and step-down transformers, and since this type of apparatus can, by the use of oil or other means, be insulated to any desired extent, it is the difficulty of insulating the line rather than the machinery which limits the voltage that can be safely employed. In comparing the various systems of transmission as regards economy of material we must put all on the same basis by so designing the plant that there shall be in each case the same stress on the insulation, or, in other words, that the difference of potential between any two points in the circuit, or between any point and earth, shall not exceed the predetermined limit. The systems of transmission which have as yet been practically employed, and which alone even claim our attention here, are the following: single-phase alternating current transmitted by two wires; double-phase alternating current transmitted by four wires; double-phase transmitted by three wires; three-phase alternating current transmitted by three wires; continuous current transmitted by two wires. The last case, although practically impossible for extra high pressures, is here included because it gives us a financial standard of comparison for the other four methods of transmission. It is well known that in every circuit the different parts of which are equally well or equally badly insulated the electrical centre of gravity remains always at zero potential, and it follows from these reasons that if the circuit carry an alternating current, the absolute potential of any point undergoes cyclical change, bringing it in turn above and below the potential of the earth by an equal amount. Thus, in a circuit carrying 10,000 effective volts, the greatest potential difference between two points will be 14,000 volts, and the greatest possible value of the absolute potential will be 7,000 volts, positive or negative. The insulation to earth will therefore be put under a stress not exceeding 7,000 volts; if, however, one point on the line were earthed, the stress at every point would immediately rise to 14,000 volts. We can now compare the continuous and single-phase alternating current as regards weight of copper required for the line, assuming in both cases the same total power and the same efficiency of transmission. Let us fix the greatest permissible stress at 7,000 volts from the earth, then it will be immediately clear that the effective voltage of transmission in the case of the alternating current is 10,000 volts, and in the case of continuous current 14,000 volts, and since the weight of copper for equally efficiency conditions varies inversely as the square of the pressure, it follows that the transmission of power with alternating current requires twice as much copper as continuous. With two-phase currents and completely duplicated circuits—*i.e.*, four wires in a line—the same holds good, as will be obvious on considering that each circuit has half the power; but how does the case stand if we bunch two of the wires? In this case we have half the current in each of the external wires, and about 70 per cent. of the current in the middle wires, resulting apparently in a saving of copper.

* Paper read before the British Association.

is a fallacy; not only is there no saving of copper, but we require actually more copper than with a single-phase system, on the four-wire double-phase system. The reason being that if we tie two of the terminals together we forcibly displace the electrical centre of gravity of each circuit, causing the potential of the other terminals to vary between wide limits. To keep the stress on the insulation down to given limit, we must therefore lower the voltage of each circuit, and this means that we must use more copper in the line. Similar investigations made for the three-phase system shows that the effective voltage in each circuit must be lower than with a continuous current, but may be higher than with a single-phase alternating current. I shall not occupy time by giving the mathematical investigations of the various cases previously mentioned, but will simply state the practical result. If we put all the systems on the same footing as regards efficiency of safety of insulation we find the following: If for the transmission of a certain power over a given distance by continuous current, 100 tons of copper are required for the line, then the single phase alternating and the two-phase four-wire system will require 200 tons, the two-phase three-wire system will require 290 tons, and the three-phase three-wire system only 150 tons. As far as the line is concerned, there is thus a distinct advantage in the employment of the three-phase system.

ON A NEW FORM OF VARIABLE POWER GEAR FOR ELECTRIC RAILWAYS AND TRAMWAYS.*

BY W. WORBY BEAUMONT, M.INST.C.E.

It is a matter of great importance on electrical railways and tramways that the maximum steam-engine power at work in the generating station should be as little above the mean load as possible.

It is found on electrical railways now at work that there is a great waste of power, and therefore of fuel, in consequence of the large consumption of current in getting the trains into motion by motors attached directly to the axles. On the South London Railway it is found that the power employed electrically in overcoming the inertia of the train is from 25 to 50 and 60 per cent. greater than that required to keep the train going.

Mr. J. H. Greathead, M.I.C.E., the engineer of this railway, has shown that if this could be avoided, from 20 to 30 per cent. of the engine power, which must under present conditions be kept running, might be shut down. The author showed this by diagrams representing the variation in the consumption of power in the working of this railway, as given by Mr. Greathead.†

For several reasons the employment of geared locomotives is undesirable on railways, although single-reduction gearing is most generally adopted for tramways, and probably will remain best for that purpose. The noise made by high-speed gearing, and the wear, are both objectionable, otherwise a geared locomotive offers the means of overcoming to some extent the losses referred to.

In the paper the author showed how an intermediate course can be adopted which will remove the loss of power at the generating station. The electric motor is placed directly on the driving-axle, but is reduced in size and power to more nearly that of the mean horse-power required on the road. This, for the greater part of the journey of a train from station to station, drives the axle upon which it is placed, at its own speed, just as those do which are now upon the South London Railway. The motor is, however, on a hollow spindle, which drives the axle when starting a train, through the medium of a compact double clutch containing one pair of epicycloidal reducing wheels. The clutches are operated by electromagnets in one case and by fluid pressure in another.

Power Gearing for Electric Locomotives.—In Figs. 1 and 2 the gearing is shown as operated by fluid pressure, and arranged as for a locomotive for direct driving. On the axle, C A, is fixed a disc, B, containing an annular cylinder, or rather chamber, in which is an annular piston, P, which, by admission of oil under pressure, or air from the continuous-brake cylinders, is caused to press, when necessary, against gripping ring, C. On the end of the motor shaft, A, is fixed an excentric, D, which gives a gyrating motion to the toothed ring, E. This correspondingly gives motion at a slow rate to the gear ring, F, which is fixed to the disc, B. Upon a projecting part of the internal gear ring is a bridle with an arm, E¹. This arm is free to slide in a bridle, O, pivoted in a ring, G. The ring G is either permitted to run free or is held fast by parts which constitute a brake clutch, of which only the ring, H, and levers, L, are seen.

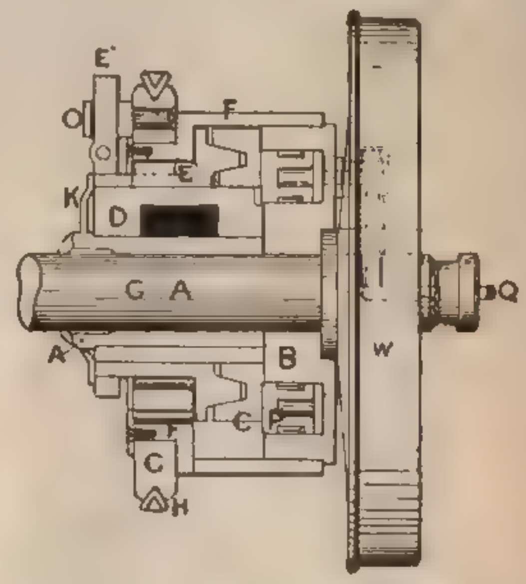

FIG. 1.

When it is desired to start a train, the ring G is held fast by this apparatus, and O becomes a fulcrum, about which E¹, with the ring E, gyrates. The locomotive axle is then driven by the wheel or ring F at one-fifth the speed of the motor, or a power ratio of 5 to 1. This is required for a few seconds at each start. The inertia of rest of the train having been overcome, the ring G is set free, and fluid under pressure admitted at Q, thus pressing

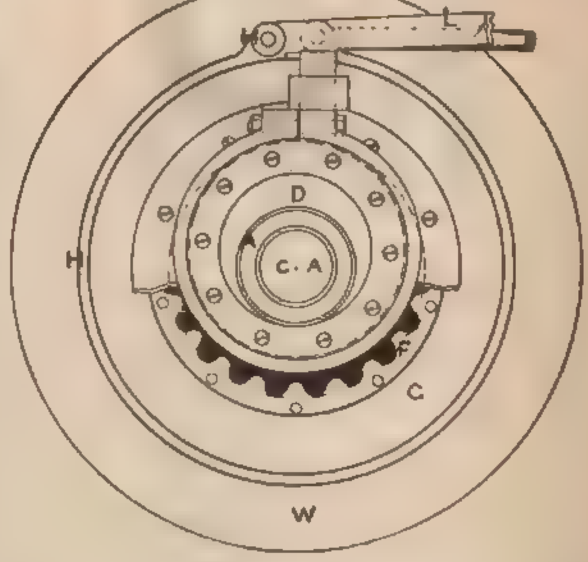

FIG. 2.

the ring C upon E. This fixes the whole of the working parts of the gear, and couples the motor shaft and locomotive axle, so that the latter is direct driven. The motor can thus run idle, driving nothing, or it may drive the axle at one-fifth of its speed or at its own speed. When running at normal speed, the whole of the gear described runs as one solid piece, and only works for starting a train

* Paper read before the British Association.
† *Proceedings, Institution of Civil Engineers*, vol. cxii.

or getting up hill. A breakdown would leave the locomotive in the condition of a gearless engine.

The arrangement of the gearing for tramcars when single-reduction gear is employed, is shown in Figs. 3 and 4. In this the motor shaft, A, carries a disc electromagnet, B, which has, as an armature, a disc, C, on the boss of the pinion, J, which gears into the wheel, J^1, on the car axle,

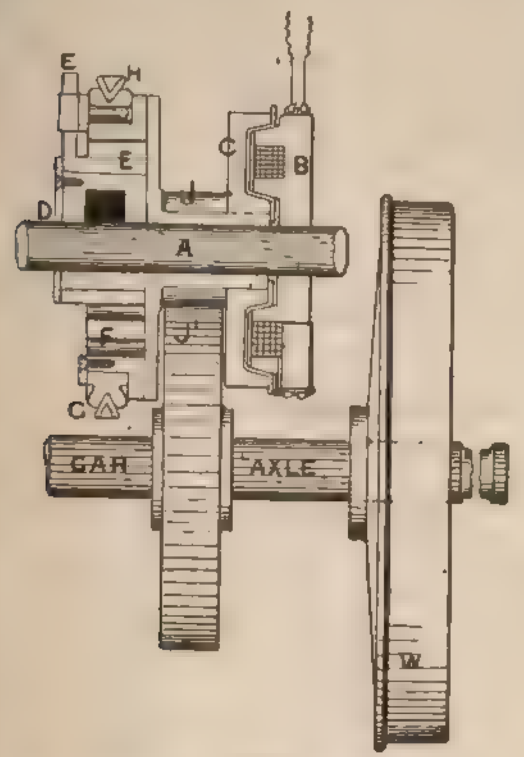

Fig. 3.

the ratio being 4 to 1. The epicycloidal gearing is very similar to that in Figs. 1 and 2, and gives, as shown, a speed ratio of 5 to 1. With this arrangement a motor of 15 h.p. would be ample for any tramcar instead

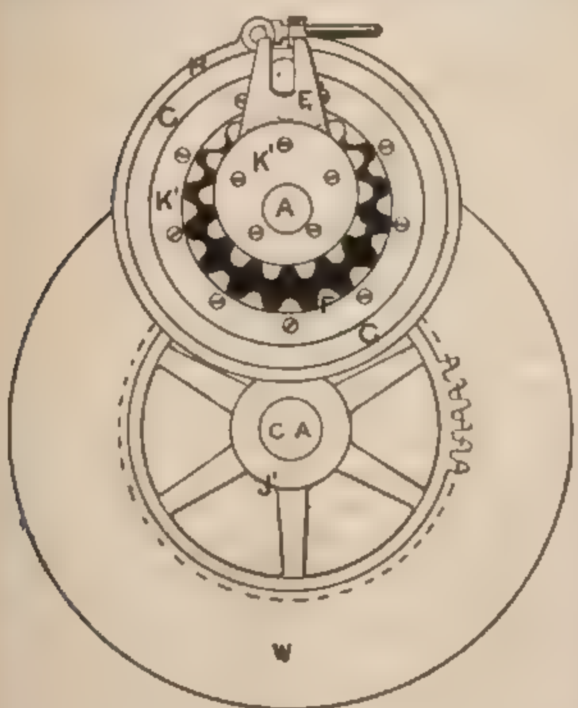

Fig. 4.

of the 30 h.p. now used. The motor in starting may run idle, or may drive the car axle through the epicycloidal gear and single-reduction gear at, say, a ratio of 20 to 1, or by passing a current into the coils and by energising the magnet, B, the whole apparatus runs solid on the motor shaft, the gear ratio then being that of the single-reduction gear of 4 to 1.

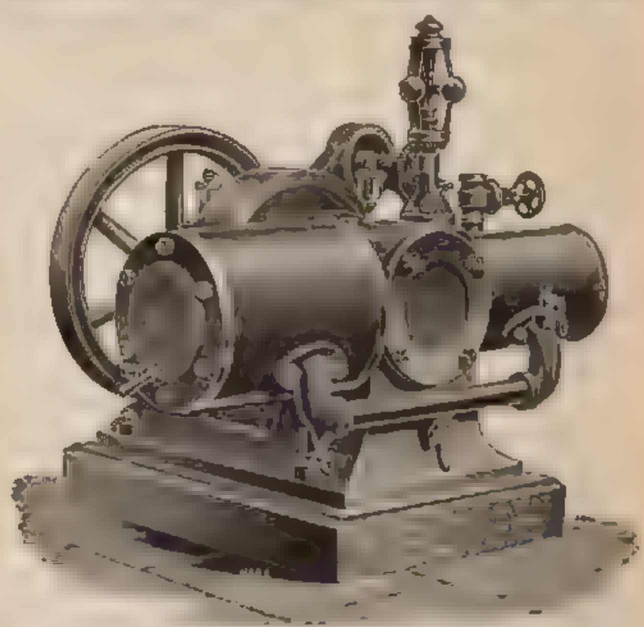
TRADE NOTES AND NOVELTIES.

THE "WILLIAMS" VALVELESS HIGH-SPEED ENGINE.

In the accompanying illustration is shown a new and novel type of high-speed engine which is on view for the first time at the Laundry Exhibition, which closes to-morrow at the Royal Agricultural Hall, Islington. Our illustration represents a 5-h.p. single-acting horizontal compound engine, the high-pressure cylinder of which is 4½in. diameter, the low-pressure cylinder being 6 11-16in. + 1 32in., and the stroke 4in. We are informed that on a trial with the engine running at a speed of 420 revolutions per minute, with a boiler pressure of 120lb., the power developed was as follows:

Indicated horse-power, high-pressure cylinder...	3·084
Indicated horse-power, low-pressure cylinder...	2·152
Total indicated horse-power	5·236

While on the brake it gave 4 9 h.p., the mechanical efficiency of the engine in terms of $\frac{\text{B.H.P.}}{\text{I.H.P.}}$ 100 = 93·583 per cent. The consumption of feed-water by actual weight pumped into the boiler by hand was 165·45lb. per hour; this corresponds to 31·59lb. per indicated horse power hour, and 33·765lb. per brake horse-power hour. At another trial with the same engine developing 6·24 i.h p., the consumption of feed-water was found to be as low as 30lb. per indicated horse-power hour.



These results are very satisfactory for an engine of such small power. It will be evident that the engine is economical. But this is not its only feature, as it is remarkable in respect of its simplicity of construction. The engine has only three working parts, comprising the piston, crank-shaft and crank (which are one forging), and the crank-pin bearing. The engine has no steam-chest, no slide or other valves, no valve-rods, no eccentrics, slides, slide-bars, piston-rod, connecting-rod, pins or joints, and no stuffing-boxes or packing of any kind, not even piston rings or grooves in the pistons, which latter are a perfectly steam tight working fit in their respective cylinders. The pistons act as their own steam-distribution valves, and can be arranged to cut off steam at any part of the stroke, and to work with any degree of expansion with no addition to the mechanism. The engine exhibited at the Laundry Exhibition is of the simple horizontal type, having two single acting cylinders, each 6½in. diameter by 4in stroke. It is working continuously 12 hours per day at a speed of 420 revolutions per minute, and with 80lb. initial pressure will indicate 16 h p., and is guaranteed to give 14 4 h.p. on the brake, or an efficiency of 90 per cent. Steam is supplied through 90ft. of partially covered pipe from a vertical boiler, and it exhausts through 120ft. of pipe and seven bends; notwithstanding these adverse conditions and the consequent back pressure due to the exhaust steam and water in the pipe, the engine is working at the speed above named with absolute silence and freedom from vibration. The makers state this same engine will develop 25 i.h.p. with an initial steam pressure of 115lb. per square inch. It occupies a space of 3ft. 9in. by 3ft. 3in. by 2ft. 3in. high, and weighs approximately 11cwt.

The engine, which has been invented and patented by Mr. T. H. Williams, A.M.I.C.E., is exhibited by the sole Messrs. Glover and Hobson, Albert Iron-w[illegible] road, Old Kent-road, London, S.E.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d
Other Places..................	4s. 11d	..	9s. 9d.	..	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

ONE AND NINEPENCE, SUBJECT.

It may be wondered whether any criminal—not utterly hardened—has awaited the gradual expiry of his fourteen years' sentence with greater eagerness and joyful expectation than very many of those interested in the electrical industry would appear to do for the termination, after a similar interval, of the incandescent lamp monopoly in this country. From time to time opinions respecting the influence of these patent rights upon the progress and development of electric lighting have been very freely expressed, and the most sanguine hopes formed with regard to increase of business when the market is thrown open next November for the indiscriminate manufacture and supply of incandescent lamps either to the trade or private users. It is not our province, however, to justify the policy of the Edison-Swan Company, even if this were necessary; the directors of that corporation owe a first duty to their shareholders, and therefore look upon the matter, as anyone would, purely from a business point of view, making the most of opportunities thus afforded to develop their own enterprise and strengthen its position against inevitable competitors.

Satisfaction, however, may be expected on all sides from this time forth: consumers, both present and intending, will be called upon to pay less than half the present price for the incandescent lamps which are an absolute necessity of their installations, and which hitherto have made no inconsiderable difference in the first cost and operation of such. Electrical contracting firms ought, as a consequence, no longer to be met by clients with the objection that they prefer to wait until lamps are cheaper before lighting their rooms by electricity; central stations will benefit correspondingly by increased output; and, lastly, it may be expected that the lampmakers themselves—though not enjoying the large profits hitherto possible—will continue to reap a fair harvest from the sale of reliable and efficient lamps at eighteenpence each, practically double the actual cost.

All these glowing prospects are to follow upon the action of the Edison-Swan Company in reducing—as noted elsewhere—the price of their lamps from 3s. 9d. to 1s. 9d. each, in anticipation of the expiry of their master patent in November next. It was, of course, to be expected that some such action would be taken, since no likelihood existed of the courts prolonging the life of this patent, even had they been petitioned to do so. The sole reason for adopting such a course would be to show the absence of any material profits upon or opportunity to develop the manufacture and sale of the lamps—a position hardly to be claimed by the Edison-Swan Company. In order, therefore, to anticipate the influx more especially of cheap and inefficient lamps from abroad, the Edison-Swan directors have given this early notice of their intentions; and to that extent deserve full credit from the trade generally.

There are several interesting topics connected with this announcement that should at the present time receive careful attention, and comment upon them in these pages is therefore particularly *à propos.*

In the first place, it is to be remembered that although flashed carbon filament lamps may be manufactured by anyone who desires to do so, there are two reasons why the Edison-Swan Company will have an enormous advantage over all other makers, inasmuch as they are in possession of experience — both technical and general — acquired during the past decade, of a kind that time alone can give at the expenditure of no small sum of money, and they also own what are practically master patents upon the lampholders that will, of course, bring in a revenue corresponding with the increase of lamps employed, though the individual profit on these appliances is much less than has been the case with the lamps.

Each of these reasons would without doubt be sufficient in itself to secure a great part of the trade to the present makers, for obviously there is no real saving in the purchase of cheaper lamps that have a correspondingly shorter life for an equal candle-power and efficiency. In the case, for example, of an 8-c.p. lamp taking 3·5 watts per candle, it may be assumed that the normal life will be one thousand hours ; if instead of two such lamps, at 1s. 9d. each, three cheaper ones be purchased at 1s. each (which is probably the minimum price for a lamp worth picking up), the life of each of the latter must be at least seven hundred hours to effect a saving of sixpence on the first cost. Unless and until, therefore, home or foreign makers other than the Edison-Swan Company are in an equally good position to ensure the output of reliable lamps, it is to be hoped for the sake of consumers and the credit of electrical contractors and supply firms that the reduction now made by the Edison-Swan Company will prove sufficient to secure them — apart from any other consideration — the greater part of the trade.

The question of profitably overrunning lamps is another matter altogether, which deserves extended attention in greater detail than is possible in this place. There is no doubt that in many cases it will be found of great advantage to deliberately shorten the life of lamps by overrunning them, if the extra candle-power thus given has a greater value to the consumer than the increased cost of more frequent renewals, as compared with those due to normal operation. Whether the first cost is now sufficiently reduced to allow of this being extensively done, depends entirely upon the efficiencies that are possible with the lamps—that is, whether the same quality will be maintained as before. If it could be proved in the end economical to run lamps at 2·5 watts per candle, considerable gain might result, not only to the consumer, who thereby gets more light for his money, but eventually to the supply stations also.

The electrical trade may congratulate itself upon the prospects before the industry. These are confessedly brighter now than ever they have been, and the ardent hopes so freely expressed of late years as to what might be done when lamps were cheaper, and public confidence thoroughly regained, stand now—or never—in the position of early accomplishment.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TRANSMARINE TELEPHONY!

SIR,—In your last two issues there has been a good deal concerning long distance telephony and its results. I should like to call attention to some experiments. I was recently present at a new invention in this direction, and by which direct speaking to any part of the world can now be accomplished. By the courtesy of the inventor, Mr. Chas. Bannister, F.O.S. (a great authority on electrical matters and engineering), I shall be able to supply you with some information which will, no doubt, be very interesting to your readers and the electrical world in general.

The "transmarinephone," as the new invention is called is certainly more powerful than the present telephone, and its construction is different in many points. For instance, in speaking into the mouthpiece, which contains a number of small coils, the sound is instantly reproduced at the other end, on the same principle as a telegraph, no matter how long the distance, as the mechanism at one end causes the other to act in the same manner, thus getting a perfect articulation. The sound is thrown on a metallic kind of shutter, which acts upon a pivot opposite a number of coils, which in turn operate upon spring armatures, then pass through several magnets of the motor principle, opposite which is a number of platinum discs tipped with indiarubber. Then this is connected by cable to the ear piece of the other instrument, which contains some other electrical apparatus, and is so sensitive to sound that the beats of a man's heart can be distinctly counted at a great mileage off between the two instruments. The great thing with this invention is that it requires no relay of battery power, so that any distance of sea may be crossed ; but I may mention that the batteries used are of particular construction.

I was given to understand that a company will be formed for the purpose of using the instruments between London and New York, Australia, India, etc., which will no doubt be a great boon to merchants trading with the above parts to be able to speak from their London office to that situated abroad. Later on no doubt I shall be able to furnish you with more particulars on this interesting subject.—Yours, etc.,

F. L. CRAMER,
Consulting Engineer.

Regent's Park, N.W., September 16, 1893.

[We insert the above letter with a purpose. In it we have a hint as to company formation. No doubt it is easier to form a company for growing marigolds in the moon than for some legitimate operations—and possibly the marigold farm would be as remunerative to the shareholders as this transmarine telephonic company, even with the use of Mr. Bannister's invention. We—all journalists do like to pretend we know the great authorities on our special subjects : hence our not knowing how far Mr. Bannister may really claim an authoritative voice must be put down to our ignorance rather than to his modesty in keeping so long out of our sight. One word to would be inventors—try to understand the problem to be solved before attempting the solution.—ED. *E. E.*].

ON A PIEZO-ELECTRIC PILE.*

BY LORD KELVIN.

The application of pressure to a voltaic pile, dry or wet, has been suggested as an illustration of the piezo-electric properties of crystals, but no very satisfactory results have hitherto been obtained, whether by experiment or by theorectical considerations, so far as I know. Whatever effects of pressure have been observed have depended upon complex actions on the moist or semi moist substances between the metals and electrolytic or semi-electrolytic and semi-metallic conductances of the substances. Clearing away everything but air from between the opposed metallic sur-

* Abstract of paper read before the British Association.

faces of different quality, I have made a piezo-electric pile, which accompanies this communication. It consists of 24 double plates, each eight centimetres square, of zinc and copper soldered together, zinc on one side and copper on the other. Half a square centimetre is cut from each corner of each zinc plate, so that the copper square is left uncovered by the zinc at each of its four corners. Thus each plate presents on one side an uninterrupted copper surface, and on the other side a zinc surface, except the four uncovered half square centimetres of copper. A pile of these plates is made, resting one over the other on four small pieces of indiarubber at the four copper corners. The air space between the opposed zinc and copper surfaces may be of any thickness from half a millimetre to three or four millimetres. Care must be taken that there are no minute shreds of fibre or dust bridging the air space. In this respect so small an air-space as half a millimetre gives trouble, but with three or four millimetres no trouble is found.

The lowest and uppermost plates are connected by five wires to the two pairs of quadrants of my quadrant electrometer, and it is generally convenient to allow the lowest to lie uninsulated on an ordinary table, and to connect it metallically with the outer case of the electrometer.

To make an experiment—(1) connect the two fine wires metallically, and let the electrometer needle settle to its metallic zero.

(2) Break the connection between the two fine wires, and let a weight of a few decigrammes or kilogrammes fall from the height of a few millimetres above the upper plate and rest on this plate. A startlingly great deflection of the electrometer needle is produced. The insulation of the indiarubber supports and of the quadrants in the electrometer ought to be so good as to allow the needle to come to rest, and the steady deflection to be observed, before there is any considerable loss. If, for example, the plates are placed with their zinc faces up, the application of the weight causes positive electricity to come from the lower face of the uppermost plate, and to deposit itself over the upper surface of plate and weight and on the electrode and pair of quadrants connected with it.

ON THE PUBLICATION OF SCIENTIFIC PAPERS.*

BY A. B. BASSET, M.A., F.R.S.

Two suggestions have been made with regard to the publication of scientific papers—first, that all papers of importance should be published in a central organ; secondly, that a digest containing an abstract of such papers should from time to time be published.

I do not think the first scheme could be carried out so as to serve any useful purpose; for although it might suit the requirements of a few juvenile societies, it is unlikely that societies of position and standing, which have ample funds at their command for the publication of their *Proceedings* and *Transactions*, would consent to sink their individuality by giving up the publication of papers communicated to them. Moreover, as many societies derive a considerable portion of their income from the sale of their *Proceedings*, it would be impossible for them to allow the concurrent publication of papers in the central organ, as this might seriously diminish their revenue.

The importance of distributing copies of papers in quarters where they are likely to be read has been alluded to in *Nature* by more than one correspondent. In order to do this effectively, it is necessary that the author should receive a certain number of gratuitous copies. These are supplied by most scientific societies, and also by many of the American and foreign scientific journals. On the other hand, the *Philosophical Magazine* refuses to present authors with any gratuitous copies, but makes them pay for any that they require. The question therefore arises as to whether the proposed "central organ" is going to conduct its business on the principle embodied in the Latin maxim, "Do ut des, do ut facias, facio ut des, facio ut facias," or whether it intends to follow the example of the *Philosophical Magazine*, and try to get all it can without giving anything in return.

It appears to me most improbable that important and prosperous societies like the Cambridge Philosophical and the London Mathematical (to say nothing of the Royal) would lend a hand in promoting the scheme of a central organ; and in that event the scheme could not possibly be successful unless it were able to offer far greater advantages and attractions to authors than the societies do.

The only feasible scheme seems to be the publication of a digest of papers by the co-operation of the various scientific societies; and, if thought desirable, papers published in foreign countries might also be included. In order to prepare the way for such a digest, I should strongly recommend that in future all societies should follow the example of the Incorporated Society for Law Reporting, and require authors to append a headnote to their papers briefly setting forth the object of the investigation. Every three or four years the titles and headnotes of all papers relating to each separate branch of science should be copied out and arranged in proper order, and a series of digests of each separate branch of science should be published. Mathematicians would thus be enabled to purchase the mathematical digests, and chemists the chemical ones. They would thereby be in a position to find out at a glance what papers have been published on their own special subjects during that period. These digests would do for science what the digests of law cases have done for the legal profession. Thirty years' experience has shown that this scheme would work well in practice, and as many country solicitors take in the "Law Reports," any member of the British Association who desires further information can easily obtain it by applying to one of the leading firms in Nottingham.

To develop an existing periodical which is a well-known and paying concern is often more successful than to start an entirely new one; and as many authors who contribute papers to societies send abstracts of them to *Nature*, it might be worth while considering whether an arrangement could not be made with the proprietors of *Nature* by which a supplemental number could be issued, say, once a quarter, containing a digest of the most important papers published in the United Kingdom during that period. The abstracts, with possibly a little pruning, and also the type used in setting them up, would be available, and the cost of compiling the supplemental number would have to be met by a small extra charge for it.

A committee of members of the British Association might be formed with advantage for discussing this matter, and drawing up a report embodying the recommendations at which they arrive. A copy of the report should then be sent as soon as practicable, without waiting for the meeting next year, to the presidents of the principal scientific societies, in order that it may be laid before their respective governing bodies. Each of the societies which are concerned with free and applied mathematics and approve of united action could then appoint a delegate to discuss further proceedings with regard to their own particular subjects, and the same could be done by societies connected with other branches of science.

* Abstract of paper read before the British Association.

NOTE ON THE UTILISATION OF WASTE WATER POWER BY ELECTRICITY.*

BY ALBION T. SNELL.

On the Continent water power is extensively used for driving electric plants, but in Great Britain, for a similar purpose, power is usually derived from the combustion of coal. This difference in practice is partly the result, no doubt, of the relative supply of water power in the neighbourhood of places where electric plants would prove commercially profitable; but it is also largely due to the relative cost of fuel. We do not possess abundant natural sources of water power in or near our large manufacturing districts, and even if we did it is not probable that with coal at the average price of the last 10 years water power would prove much cheaper when the capital invested, interest, and cost of maintenance of the electric plant were taken into consideration. But we may with reason pause to ask two questions: Will coal at such a price be always obtainable? And do we make the most of such water power as we have and can profitably use? Let us look at the second question first. Liverpool is

* Paper read before the British Association.

supplied with water from Lake Vyrnwy, in North Wales, the total difference of head being about 500ft. There must be a considerable quantity of power in the conduit. Is any of it utilised? And if not, does the reason lie in the fact that fuel at present is so cheap? Could the Manchester Waterworks, which form a magnificent series of artificial lakes, be utilised to drive turbines and give electric energy for lighting the various towns in their vicinity? Again, the watershed behind Greenock has a fall of many hundred feet, and the water is only partly utilised to drive mills. These are only a few instances in which water power might, perhaps, be advantageously used for driving turbine-dynamos. There are, of course, numerous mountain streams which could be dammed, and thus converted into reservoirs for feeding turbines.

England has been so prosperous in the past by reason of large supplies of coal, hitherto cheap and certain, that the consumers of power have scarcely realised the necessity of any change, and can with difficulty be brought even to contemplate the utilisation of waste water power. On the Continent, however, coal is found in only a few districts, and fuel is generally dear in comparison with the prices current in Great Britain, and dearer still in relation to local wages and prices. Necessity has thus prepared Swiss, German, and Italian manufacturers for a radical innovation which gives them a cheaper power by utilising mountain streams. It is no mere figure of speech to say that natural obstacles in the way of trade competition have led to the development of this important branch of engineering on the Continent, while the very prosperity of Great Britain has tended to hinder progress in this direction. We may ask ourselves in all seriousness whether the present price of coal is likely to be maintained, and whether it would not be wise to make the most of such water power as we have by using it as an adjunct to, if not as a substitute for, coal. This is quite possible in many places, since power can be transmitted electrically at high pressure for distances of 20 miles or so with a loss not exceeding from 15 to 20 per cent. There is still much misconception on the part of the responsible advisers of manufacturers and mineral owners as to the possibilities of electricity for the transmission of power, and a lingering distrust, largely due, no doubt, to the financial booms in electric stocks some 10 years ago. But the experience gained during the last decade is gradually making itself felt, and the most conservative must admit it has given us the means of utilising natural water power in a far more efficient manner than was formerly possible.

The following brief reference to a few of the continental plants will give an idea of some of the methods of utilising water power.

Furstenfeld-Bruck.—This installation is illustrative of how a small town may be supplied by electricity for lighting and power purposes when there is water power in the neighbourhood. The power station in this case is about four and a half miles distant from the town. There are two alternators of 38 kilowatts each, driven by turbines. The alternators work in parallel at 2,600 volts, and are driven by belting from the main shaft of the turbines. The transmission conductors are two copper wires, ¼in. in diameter, carried by insulators on posts. At the distributing station there are 10 transformers, whose secondary circuits feed the distributing network at 100 volts pressure. The secondary network is above ground, there being no need to incur the extra expense of laying it in culverts. Single-phase alternate-current motors are running on this circuit. The turbines are designed for a total output of 180 h.p., equivalent to about 4,000 lamps of 8 c.p. at Furstenfeld-Bruck, and another dynamo will be added as soon as required. At present the load consists of 3,000 lamps of 8 c.p., seven arcs, and motors aggregating about 18 b.h.p. The cost of installation, including secondary cables of sufficient size to serve all the houses in the town, is about 16s. 6d. per 8-c.p. lamp at present installed; and the cost of running is estimated at 10s. per lamp, on a basis of 2,400 lamps burning at the same time. The charge for private lighting calculated for these figures is about 5½d. per unit.

Tivoli Station for the Electric Lighting of Part of Rome.—This installation is unique in many respects, and is worthy of special consideration. Its full capacity is about 2,000 e.h.p. The waterfalls of Tivoli, about 330ft. in height, and averaging 40 cubic feet per second, form the source of power. The main channel has been arranged to feed three pipes, each of which feeds three turbines of the Girard type, two of 330 h.p., and one of 50 h.p., all being coupled direct to dynamos running at 170 and 375 revolutions per minute respectively. The whole of this apparatus is underground. The large alternators give 45 amperes at 5,000 volts, and are coupled in parallel. The smaller turbines run the exciters, which are each capable of exciting three alternators. The length of the high pressure line is about 17 miles, and there are four naked conductors carried on oil insulators. The transformer station is near the Porta Pia, just outside the walls of Rome, the pressure there being about 4,000 volts, so that the drop of pressure on full load is about 20 per cent. In the station are two banks of 16 transformers each, which reduce the pressure to 2,000 volts in the secondary mains. Transformers are installed on the premises of the different consumers to reduce the 2,000 volts to the supply service of 100 volts, and there are also transformers capable of feeding 600 arc lamps for street-lighting, of which about 250 are already installed.

Lauffen-Heilbronn.—This installation is an example of power transmission by rotary or multiphase currents. The power station has four turbines of 330 h.p. each, running at 35 revolutions per minute, with 3·85 metres fall. The alternators are coupled through gearing, and each gives 4,000 amperes at 50 volts. This current is passed through the primary circuit of a step-up transformer, and is raised to a pressure of 5,000 volts. At this pressure the power is transmitted through three bare copper wires, insulated by means of oil insulators on high poles. At Heilbronn, step-down transformers reduce the pressure to 1,500 volts, and feed the distributing network on which the house transformers are placed, the final pressure at the consumer's terminals being 100 volts. Several large motors and a number of small ones are run off the circuits, the distribution of power in small units being one of the special objects of the installation. These motors are self-starting, and of very simple construction, the small ones having neither commutator nor brushes, and the larger ones not commutators, but only collecting rings and brushes to admit of adjusting the exciting current. The price charged for lighting is, approximately, 9d. per Board of Trade unit, while for motors and heating purposes the price is fixed at 4d., and there is also a sliding scale which gives reductions to large consumers. The total cost of the works is said to be, roughly, £13,000, and there are at present about 4,000 lamps of 8 c.p., 20 arc lamps, and about 20 motors. The full capacity of the plant when finished will be 19,000 lamps of 8 c.p., or their equivalent in power.

The Genoa Power Station.—At 30 kilometres from Genoa, at a height of about 550 metres above the sea-level, dams were thrown across two valleys, and thus formed two artificial lakes, having together a capacity of about 4,600,000 cubic metres, and capable of supplying 500 litres of water per second. About 140 metres of the total head were utilised for some years to drive more than 300 small hydraulic motors, and the remaining head of about 364 metres was wasted. In 1888 arrangements were made to utilise this power electrically, and in order to get the maximum effect from the head three reservoirs were constructed at different levels. The first reservoir is 130 metres below the main outlet; the second, 108 metres lower; and the third, 144 metres below the second. A power station is built at each reservoir, the available water power at each being respectively 746 h.p., 720 h.p., and 960 h.p. These are named after three of the most celebrated Italian electricians, the highest being called the Pacinotti Station, the middle one the Volta Station, and the lowest the Galvani Station. The plan of operations is to drive constant-current dynamos at these stations, and to transmit the power to a number of widely separated motors coupled in series, the pressure being varied at the stations according to the load on the circuit. The most distant motor is 30 kilometres away, and the total length of the conductors exceeds 100 kilometres. To the three stations are coupled two circuits of copper wire 9mm. in diameter, bare throughout most of its length, but insulated where it passes through villages and laid in the ground when crossing railways. The maximum pressure employed is about 8,000 volts, and the minimum about 450, which just suffices to drive the current of 47 amperes through the circuits. The dynamos are six-pole Thury machines, and are each designed for about 1,000 volts and 47 amperes. At "Galvani" there are two such dynamos self exciting and coupled directly through flexible couplings to a Girard turbine giving 150 h.p. at a maximum speed of 475 revolutions per minute. The regulation is accomplished by varying the speed of the turbine by a throttle valve worked by hand, this device, of course, being only applicable to a single unit. At the "Volta" station the generating plant consists of four groups of machines, each of one 140-h.p. turbine coupled direct to two dynamos of 1,000 volts and 47 amperes each. These eight dynamos are connected in series, and are, therefore, able to supply current at a maximum pressure of 8,000 volts. At this station the speed of the turbines is maintained constant, the regulation of pressure being effected by varying the excitation of the dynamos, which are separately excited from a machine driven by an independent turbine, the speed of which is varied by an electric regulator. These turbines were designed by Messrs. Faesch and Piccard, of Geneva, and have very sensitive governors, acting through a small motor which moves the "gate" of the regulating turbine. These keep the speed constant within about 2 per cent., even when half the load is suddenly taken off. The dynamo armatures are made as heavy as possible to assist the governing. This method of regulation, however, is found to cause trouble from insulation difficulties, and, therefore, at "Pacinotti," which was the last of the three stations to be erected, variable speed with self-excitation was again resorted to. The turbines and dynamos are here practically the same as at "Volta," excepting the arrangement for governing the current which is accomplished by a most ingenious device

each turbine is controlled by a 1-h.p. motor, worked by relay currents. The armatures have two oppositely wound circuits, each with a separate commutator, and revolve to the right or the left, according as one or other of the circuits is traversed by the relay current. A sensitive ammeter is used to make the contacts, and, since the four turbines are acted upon simultaneously by the four motors, a very quick and effective regulation results. The moving parts are made as light as possible, and thus tend to maintain the current constant, for the speed varies inversely as the torque, and therefore the automatic regulator has very little work to do. The arrangement is so sensitive that although the pressure frequently varies in a few seconds from 8,000 to 2,000 volts or less, the current is practically constant.

Cassel Plant. This installation is especially interesting as an example of the utilisation of alternate current transmission and direct-current distribution. The power station is some miles from Cassel, and consists of two turbines and two high pressure alternators. These are coupled in parallel, and the current is carried by a concentric cable to two sub-stations, in each of which there is an alternate-current motor. Each station has two continuous-current dynamos coupled rigidly, with the alternate-current motor between them. The current is supplied to consumers at 100 volts pressure on the three-wire system, and at one of the stations there is a storage battery. These plants have been instanced because they are typical of continental practice. They differ widely, both as regards size, method, and details, but they are all designed on the broad lines of utilising waste water power, and transmitting its energy electrically to towns where it can be usefully expended. Alternate currents appear to be generally selected, perhaps because they offer more advantages than direct currents for high pressures, and are generally more easily managed. And in several cases it has been deemed advisable to use a direct-current distribution with an alternate-current transmission, as at Cassel. The Genoa installation is an exceptional case, as it is simply a power plant, and the main object is to drive a number of widely-scattered motors. Yet without a closer acquaintance with the conditions and peculiarities, the writer cannot pass an opinion on the wisdom of the choice of a constant-current service. But, at any rate, much credit is due to the engineers for overcoming the difficulties in connection with maintaining the current constant. It must also be borne in mind that this plant was practically designed before the advent of a really reliable asynchronous and self-starting alternate-current motor, and it is quite possible that in the light of modern experience a similar scheme would be dealt with by an alternate-current system. The Lauffen-Heilbronn plant is at present the only important instance of a rotary-current system, and there considerable difficulty is found in balancing the load on the two circuits. In fact, however useful the multiphase currents may be for power plants pure and simple, in which a constant pressure of supply is not necessarily of primary importance, it appears to be abundantly proved that they are not suitable for lighting, as then constant pressure is absolutely necessary. A scheme for damming the River Reuse and conveying the water to a storage and distributing reservoir, having a capacity of 3,000,000 cubic feet, at Combi Garrot, is under consideration at present. The water will be distributed to the communes of Neuchâtel, Loche, and La Chaux de Fonds, and power will be distributed electrically to distances varying from 7½ to 11 miles. This is a striking instance of the possible utilisation of water power. There are scores of turbine-dynamo plants in different parts of the Continent, varying from 20 h.p. to 500 h.p., chiefly used for driving mills and lighting small towns, and even villages. For example, the plants at Chur, Schio, Lugano, Bellinzona, Reichenhall, Macerata, etc. In England there are only a few installations which derive their power from water, such as the small central station for lighting Lynmouth and Lynton, and a few private installations. A scheme, on a large scale, for electrically lighting Worcester by means of power derived from the River Severn is in hand, and will, no doubt, lead to similar plants.

The Greenside Silver Lead Mines, Patterdale, Westmoreland.—One of the most important instances of the application of water power for electric power transmission in Great Britain at present is that at the Greenside Silver-Lead Mines in Cumberland, which was designed by the writer about three years ago in conjunction with the mine manager, Mr. Borlase. These mines are among the few that find it possible to compete with foreign mines, and this is the case partly owing to a fine grade of ore which contains a large percentage of silver chiefly extracted by crystallisation, but largely because the use of electricity for winding, hauling, and pumping has decreased the cost of working. On the east slopes of Hellvelyn lies a small natural lake called the Red Tarn, and on the north-east the impounded water of Keppel Cove. Between the two waters rises the hill of Catstycam, at the base of which the two overflows join, and near to which the Greenside Silver Lead Mining and Smelting Company have erected their turbine-dynamo station. The water is led from an elevation of 1,750ft. above sea level, and flows through an open watercourse 1½ miles in length to a large reservoir, from which it is conveyed down the hillside for a distance of 360 yards in 15in. cast-iron pipes. The fall at the station is equivalent to a vertical head of 400ft., and the effective horse power is about 200. The generating station contains one of Gilkes and Co.'s vortex turbines of 100 h.p., driving a four-pole compound dynamo made by the General Electric Power and Traction Company. The house is large enough to duplicate this plant when necessary, and pipes, watercourses, etc., are already laid for this purpose. The electric current is conveyed by two bare copper conductors on poles for six furlongs, to where it enters the mine at an elevation of 1,850ft. above the sea-level. The conductors from this point are insulated and covered with lead. About three-quarters of a mile in the mine, or 1½ miles from the dynamo, a 9 h.p. series motor is employed to wind ore from a set of sinkers. Further into the mine another quarter of a mile, and down 120 yards at the bottom level, is fixed another 9-h.p. motor, working a three-throw pump, forcing the water 360ft. in height. About midway between these motors there is fixed a dynamotor, which reduces the pressure from 600 to 250 volts for working an electro-locomotive in the lowest day level of the mine, through which runs the water pumped from the 120-yards level and the whole of the water used by two hydraulic winding engines. Four horses formerly worked this level. The locomotive runs with 12 waggons, the total weight when loaded being 18 tons, and does the work of the four horses with the greatest ease. The conductors in the level are phosphor-bronze wire, and the current is fed to the locomotive by four contact pulleys. The difficulties encountered in fixing this plant and wiring the level can only be appreciated by the practical man. All main stations in the mine are lighted by incandescent lamps in series of six. The installation reflects credit on the manager, Mr. Borlase, for his enterprise in recommending the scheme to his directors, and for his perseverance in carrying it out in the face of much opposition from the miners and others interested in maintaining the old state of affairs.

The chief difficulty attending the use of water power is the irregular and sometimes intermittent character of the supply, and hence it is necessary to exercise great care in judging the suitability of water for given work. This can be obviated to a large extent by building reservoirs and regulating the output according to the power required; but when lighting forms an important part of the scheme, secondary batteries may be used most advantageously. Accumulators act not only as reservoirs, but also as regulators, storing up excess of power, and giving it out when the prime power is insufficient or the turbines are stopped. They are, therefore, especially useful on installations for combined power and light when the water power varies intermittently. And they may be made a source of economy when power is not required both by day and by night, and owing to the want of a suitable reservoir the water runs to waste during the idle period; then accumulators may be used to store the major part of this energy for electric lighting, metallurgical, or even power purposes.

It will be gathered that the writer is fully aware the small water power of Great Britain can never show results equivalent to those obtained on the Continent, yet there is undoubtedly much water power wasted here that is capable of being profitably utilised. His object is simply to call attention to the improved means of utilising water power by turbine-dynamos, and to suggest that prompt measures be taken to conserve as much power as possible by a proper attention to the building of dams and reservoirs wherever this may be feasible. And that such power should be used, if convenient, to the exclusion of coal, and, if not so, as an auxiliary power, the steam plant being used as a stand-by as much as possible. This proposal, if properly carried out, would decrease the total consumption of coal to a greater extent than is generally supposed, and would make a number of manufacturers less dependent upon it than they are to-day, even if it did not appreciably cheapen the cost of power. But in a number of favoured cases there can be no doubt that water power properly applied would considerably decrease the cost of working, allowing a proportionate gain to both producer and consumer.

Smithfield Markets.—The work of lighting the whole of the markets is approaching completion. The total capacity of plant at present being installed is 1,000 h.p., but arrangements are being made for increasing this by 50 per cent. The plant consists of four compound vertical steam engines by Davey and Paxman, and four boilers. There is also a double-cylinder horizontal engine with locomotive boiler. The dynamos, which are directly coupled to the engines, are being supplied by the Electric Construction Company, Wolverhampton. The current is supplied from Messrs. Julius Sax and Co.'s station in Charterhouse-street to the "distributing boards" in the various markets by a number of feeders of copper strip, which have a total length of over two miles, and weigh more than 28 tons. The length of wire and main cable employed makes a total of over 90 miles.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE I.

(Continued from page 251.)

GENERATION OF POWER BY STEAM—CONDITIONS OF ECONOMY AND OF WASTE.

Sir F. Bramwell, in an address to the Institution of Civil Engineers, in 1885, indicated very clearly in a convenient phrase those conditions involving waste of fuel in steam power production which are avoided by central station working. He said that we were "every day becoming more alive to the benefit where little power is required, or where considerable power is required intermittently, of deriving that power from a central source." Where little power is required the steam engine is costly, uneconomical, and inconvenient. Where great power is required intermittently both engines and boilers work in conditions extremely unfavourable to economy. It is necessary to examine into these cases more in detail, because it is the wastefulness of working in such conditions which makes central stations desirable.

Table I. gives a careful selection of the most trustworthy results of steam-engine experimental trials. In such trials it may be assumed that everything is working at its best, and that the steam and coal consumption is the smallest realisable with different engine and boiler plants. In all these trials the engines were worked with at any rate an approximation to the most economical load. It will be seen that the steam and coal consumption is less for large engines than for small engines, less for quick engines than for slow ones, and less for compound and triple engines than for simple engines. Even under favourable test trial conditions, and with an economical load, there is considerable variation in the amount of coal and steam required per horse power.

* Howard Lectures delivered before the Society of Arts.

Taking the most favourable results which can be regarded as not exceptional, it appears that in test trials, with constant and full load, the expenditure of steam and coal is about as follows:

—	Per i.h.p. hour.		Per effective h.p. hour.	
	Coal. lb.	Steam. lb.	Coal. lb.	Steam. lb.
Non-condensing engine	1·80	16·5	2·00	18·0
Condensing engine	1·50	13·5	1·75	15·8

These may be regarded as minimum values, rarely surpassed by the most efficient machinery and only reached with very good machinery in the favourable conditions of a test trial.

It is much more difficult to get the consumption of coal by engines in ordinary daily work. What is known shows that the consumption is greater than in engine trials. Some comparatively large pumping engines, which work with a steady load night and day, and which worked with 2lb. of coal per effective or pump horse power on a test trial, used 2·7lb. in ordinary working. The consumption was measured over many weeks, during which they were working 90 per cent. of the whole time. Here the consumption is 35 per cent. greater in ordinary work than in a test trial.

The large pumping engines of the Hydraulic Power Company are less favourably circumstanced for economy. They gave an indicated horse-power on trial with 2·19lb. of coal per hour. In ordinary work they are stated to use 2·93 or about 35 per cent. more. These engines have a fairly steady load during the day and a smaller load at night.

If such a case as that of an electric lighting station is considered, where the load fluctuates very greatly, the maximum load being often four times the mean load, and the minimum load one twentieth of the mean load, then the consumption per horse power is very much greater. Mr. Crompton has given the figures for the Kensington station, which has excellent Willans compound non-condensing engines. These engines will work with less than 2lb. of coal per effective horse power in trials at full load. The results obtained in ordinary workings were as follows:

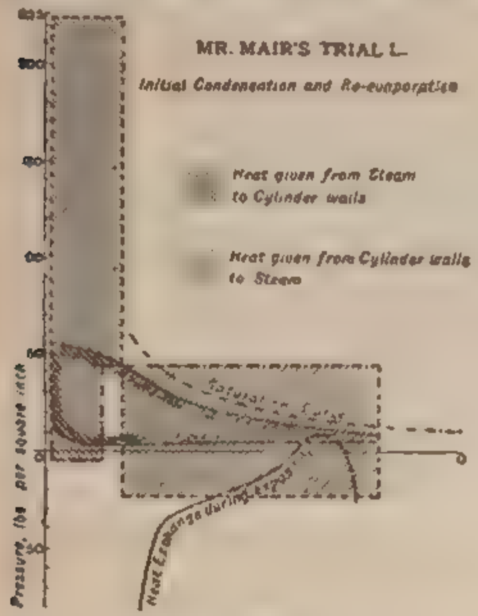

Fig. 1.

1892	7	4·9	3·8

In the discussion on Mr. Crompton's paper, instances were given of coal consumption at electrical stations still larger than any of these. Probably up to the present the consumption has in no case been less than 6lb. per unit generated; 3·8lb. per effective horse-power; or 3·3lb. per indicated horse-power. This large

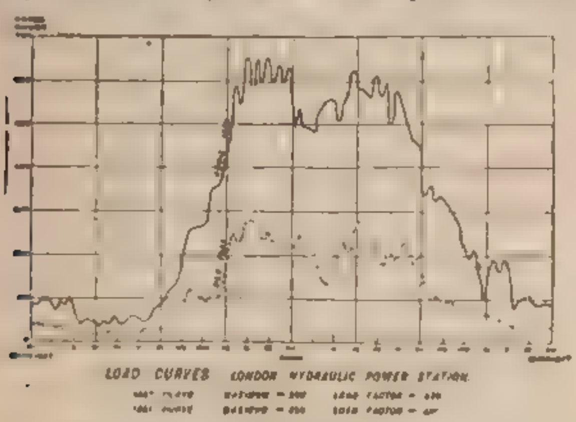

Fig. 2.

consumption will be traced later to two classes of waste—engine waste and boiler waste—due both of them to the inefficiency caused by variation of load.*

In the case of small isolated motors, not generally of very good construction or well proportioned for their work, still more extravagant results have been observed. The following Table III gives some results obtained with small workshop engines in Birmingham.

These last results are interesting only for this reason, that it is such uneconomical small engines which are displaced when central station power distribution is introduced. It is because these small engines are so extravagant that power can be distributed from a central station at profit. As to the case of electric light stations, seeing that they are central stations of the type specially considered in these lectures, it is desirable to analyse more in detail the causes of waste.

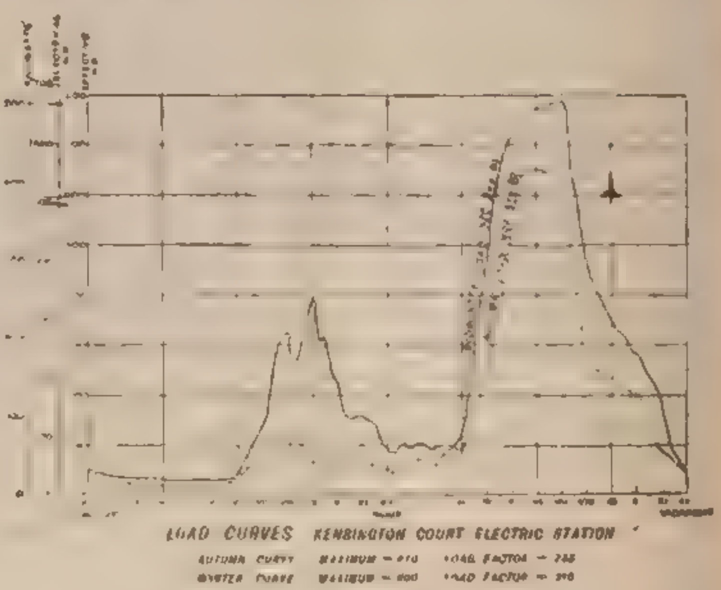

Fig. 4.

TABLE III.—Coal Consumption per Indicated Horse-power in Small Engines at Birmingham.

Nominal h.p.	Probable i.h.p. at full load.	Actual average i.h.p. during the observations.	Coal consumption in pounds per i.h.p. hour during the observations.

20	60	20·00	8·50

The Chief Secondary Cause of Loss or Waste in Heat Motors.—Thermodynamics shows that the efficiency of heat motors cannot

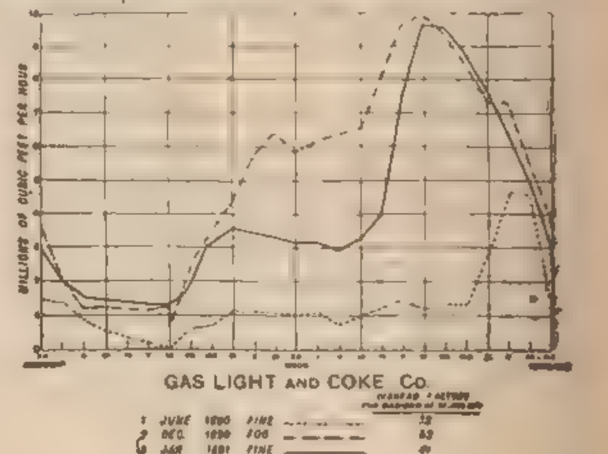

Fig. 3.

exceed a certain limit, depending on the range of temperature at which the motor works. With the range of temperature practically available a steam engine might convert three-eighths, and a gas engine one half, of the heat supply into work. No actual engine reaches even approximately this thermal efficiency. Part of the losses are due to bad construction or bad management, but a part are practically unavoidable. The principal cause of the practically unavoidable waste of heat energy is essentially the same in steam engines and gas engines; it is a consequence of the enclosure of the hot working fluid in conducting metallic walls. In steam-engines the cylinder walls condense steam during

*The latest Board of Trade returns from electric lighting stations confirm these figures. Taking the largest and best stations, the consumption of coal varies in different cases from *7lb. to 12lb. per unit* of electricity generated. It is more than *this per unit sold.*

admission, the condense steam evaporating and carrying off heat to the condenser or the atmosphere during the period of exhaust. This exhaust waste increases with the ratio of the admission surface in the cylinder to the weight of steam used per stroke. In the same engine, therefore, it increases for light loads because more surface is exposed during admission per pound of steam used. It is greater when the engine works slowly than when it works fast, the piston effort being the same. The evil can be diminished, but not entirely overcome, by steam jackets, or by superheating. It is an evil specially prejudicial when engines are used which are too large for the work to be done.

In gas engines it is necessary, to prevent destruction of the cylinder by the high temperature of the burning gases, to enclose it in a water jacket. M. Witz has shown that it is due to the cooling action of this water jacketed wall that part of the gas is kept below the temperature of combustion. The jacket therefore, diminishes the efficiency of the engine not only by directly abstracting heat, but by preventing the full development of the gas pressure early in the stroke. As in steam engines, the evil is greater the greater the wall surface exposed at the moment of explosion. This appears to be the principal reason why initial compression of the gases is necessary for good efficiency. The gases reduced by compression to a smaller volume are exposed at the moment of ignition to a smaller area of cylinder wall.

It is useful to get a clear numerical idea of the relative importance of the cylinder wall action and the other actions during a stroke, for this cylinder wall action is the principal factor in the inefficiency due to variable load or arising out of the use of underloaded engines, both matters of importance in considering the advantages of distribution of power. Prof. Dwelshauvers Dery has shown* how the heat exchange between the steam and the cylinder wall during the stroke may be represented by a diagram on the same scale as the indicator diagram. Fig. 1 shows such a diagram drawn for the data of one of Mr. Mair Rumley's engine trials. The engine was a single cylinder beam engine with jacket, working at about 4½ expansions, and furnishing 123 i.h.p. The total steam used per stroke was 1·14lb., or 31 cubic inches of water. The whole of this, if condensed and spread over the cylinder wall, would make a layer less than one hundredth of an inch thick. The range of temperature between the initial steam temperature and the exhaust temperature may be taken roughly as 200 deg., and about 30 per cent. of the steam was condensed during admission. The whole heat of this initially condensed steam would only be sufficient to heat a very thin layer of the cylinder wall from the exhaust to the admission temperature.

The dark shaded line in the figure is the indicator diagram of the engine. The saturation curve shows where the expansion line of the diagram should have been if there had been no condensation. The two shaded areas represent to the same scale as the indicator diagram the heat given to the cylinder wall during admission and compression and abstracted from it during expansion and exhaust. They represent heat quantities wasted. It will be seen easily that the cylinder wall action involves larger quantities of heat than the whole of the heat employed in doing useful work.

Load Curve and Load Factor.—A curve, the abscissæ of which represent time, and the ordinates the rate of expenditure, is called a load curve, and such curves are very commonly drawn for a period of 24 hours' working, because, apart from seasonal fluctuations, a day is a natural period in the operation of a power plant. The ordinates may be horse power or volt amperes, or units of any other quantity proportional to the rate of expenditure of energy. The area of the curve represents the total amount of energy for the period considered. A load curve may be drawn for a single engine or machine, or for a plant of many engines or machines. The load line for a central station is that to which attention is to be directed. The ordinate of such a station load curve represents the sum of the energy expended at the moment per unit of time by all the engines or machines then in operation.

Load curves for particular cases have, no doubt, been frequently drawn, and the influence of fluctuation in the rate of working on economy has been noted. But it is due to Mr. Crompton that the use of the load curve in examining the results of station working, and in discriminating the causes of differences in the results obtained in different stations, was first clearly indicated.†

It can be directly inferred from the examples given in Mr. Crompton's paper that the cost of working per unit of mechanical or electrical energy distributed in different electric lighting stations depends very intimately on the form of the load curve. Mr. Crompton introduced a term, "load factor," to express the coefficient of fluctuation of the rate of working. There may be various load factors, according to the precise fluctuation considered. But for the object at present in view, the consideration of the influence of variation of load on the efficiency of steam plant, the load factor may be taken to be the ratio of the area of a day's load curve to the area of a rectangle enclosing it. It is equally the ratio of the average load during the day to the maximum load at any time during the day. The plant must be large enough for the maximum load. The income depends on the mean amount of energy delivered. The efficiency of the engines depends on the load factor. The cost of a day's working depends partly on the average output, partly on the load factor.

Fig. 2 gives two load curves for a day's working of one of the stations of the London Hydraulic Supply Company. These indicate the kind of fluctuation of demand which occurs in a central station supplying power for a large number of intermittently working machines, chiefly lifts and hoisting machines. Such machines are in frequent use in the day and are little used at night. The demand for power water pumped by the engines at the station is large and pretty constant from 9 a.m. to 5 p.m. During the remaining hours the demand is small. The load factor for the day, understood as defined above, is 0·41 in 1887, and 0·46 in 1890, when the system had been considerably extended. This shows that as the number of consumers supplied is greater, the demand is more uniform.

Fig. 3 shows load curves for the London Gas and Coal Company. A gas generating station is essentially a central station supplying and distributing a means of producing energy either for lighting, heating, or power purposes. The ordinates in the case represent cubic feet of gas supplied per hour. If, say, 26 cubic feet of gas per hour is assumed to be capable of furnishing a horse power, it is easily seen that the ordinates of the curves to a suitable scale represent equally horse power of energy supplied. In the case of the Gas and Coke Company, the largest demand is for lighting and this is greatest in the evening. But there is also a considerable demand during the day for gas for heating and for power. The daily diagram factor was 0·41 for a day in January, falling to 0·27 for a day in June. On a foggy day in December it rose to 0·52.

Fig. 4 gives load curves for the Kensington electric lighting station. As practically the whole of the electricity generated is used for lighting purposes, the period of large demand is short, and the fluctuation of demand greater than in either of the previous cases. The daily load factor is 0·24 for one of the curves and 0·32 for the other. But for the partial use of storage batteries the load factor would have been smaller still.

THE BRITISH ASSOCIATION.

Address to the Mechanical Science Section.

BY JEREMIAH HEAD, M.INST.C.E., PAST-PRES.INST.MECH.E., F.C.S., PRESIDENT OF THE SECTION.

(Concluded from page 261.)

Weight of Birds in Relation to their Bulk.—It is generally believed that birds are lighter, bulk for bulk, than other animals, and that to this lightness they owe, in some degree, their power of flight and of floating on water. To account for this it is said that their bone cavities are filled with air, and that some, though not even all, flying birds have small air sacs under the skin. It is clear, however, that displacement of external air by air-filled cavities can only assist aerial flotation to an infinitesimal extent, unless highly heated. Such cavities would, however, help aquatic birds to swim, if situated under the immersed portion of their bodies, which is not always the case. Some aquatic birds, such as swans, swim with head, neck, wings, tail and half their bodies out of the water. The specific gravity of fishes and land animals is clearly about the same as water. For, when swimming, they can keep only a small portion of their heads above the surface, and that by continued exertion. Are, then, birds, in the substance of their bodies less dense than other animals, although also composed of flesh, blood and bone, and these components in similar proportions and of similar character and texture? If they are, then land animals might have been made lighter in proportion to their bulk or smaller in proportion to their weight than they have been. If they are not, how is it that some of them can swim and float high out of the water? Having an opportunity recently of inspecting a large wild, or whooper swan, I ascertained its weight to be 14lb. I noticed that the whole of the under part of the body, which would be immersed when swimming, was covered with feathers and underlined with down to an average depth of not less than 1½in., or, when closely pressed, say, 1¼in. The immersed surface I estimated at 1½ square feet. The weight of water displaced by this feather and down jacket, and the consequent extra buoyancy produced thereby, was no less than 9·78lb. This would account for two-thirds of the bird's body being out of the water when swimming, even if the body were of the same specific gravity as water. I next procured a freshly shot wild duck, which weighed 2¼lb., and placed it in a tank of sea water. It floated. I found the area of its immersed surface to be 54 square inches, and the average depth of its under-feathers and down to be ⅜in. The water displaced by this envelope would weigh 1·3lb., and would support three-fifths of its entire weight. I then had it denuded of all its feathers and down, and again placed in the tank. It then slowly sank to the bottom. These experiments, so far as they go, seem to prove conclusively that birds are not lighter, bulk for bulk, than other animals, but, on the other hand, about the same specific gravity, and that their floating power lies entirely in the thick jacket or life-belt with which Nature has furnished those, and those only, which are intended to swim. Inasmuch, therefore, as the specific gravity of the actual bodies of all animals appears to be about the same, there is no reason to believe that they could have been constructed of lighter material or to lighter design.

Weight in Relation to their Energy.—But notwithstanding this uniformity of specific gravity, there remains the curious fact that flying birds can exert continuously about three times the horse power per pound of weight that man can, and, indeed, about three times what is possible for the horse. This marvellous flow of energy in proportion to weight is probably due to rapidity of heart action rather than to increase of muscular stress. I have timed

sea gulls and found them to flap their wings 200 times per minute when flying at about 24 knots per hour, and have estimated eider ducks, making about 36 knots per hour, to be flapping their wings 500 times in a minute. I say "estimated," for their movements are too rapid for precise counting. This outpouring of energy, which seems to me to be unequalled in terrestrial animals, is nevertheless maintained by birds for indefinitely long periods of time. A proportionately increased rate of combustion and renovation of tissue as well as of food consumption are necessary consequences. The higher temperature of the bodies of birds, as compared with other animals,* and the well known vivacity of those which, like sea birds, are almost continuously on the wing, are circumstances which seem to point to the same conclusion. It is confirmed by what we know of steam and other motors. For instance, if a steamship were so built and proportioned that a ton of coal per hour consumed in the boilers would maintain the pressure at 100lb. per square inch, and produce 1,000 h.p. at the propeller, and then if, without other alteration, firing was slackened until the steam fell to 50lb. per square inch, and there maintained, it is clear that the horse power produced would be greatly lessened, and so would the temperature of the steam in the boilers, steam pipes, and cylinders. Thus, other things being equal, the temperature of the steam would rise and fall with the energy given forth by the mechanism. The suggestion is that the higher temperature of birds, as compared with other animals is similarly connected with their superior power of producing and maintaining energetic effort.

Aerial Navigation.

Let us now consider what man has done, and may be able to do, in aerial navigation by aid of contrivances which, as in the case of railway locomotives and ocean steamers, are propelled by a power other than that of his own body. The scientific world is greatly indebted to Mr. Hiram S. Maxim, of London, for recording in a clear and readable form the present position of aeronautic mechanisms.† So far, the only contrivances which have been fairly successful are balloons, which, unlike birds, depend on atmospheric displacement for their power of sustaining weight or rising or falling. In balloon experiments our French neighbours have led the way from the first attempt of the Montgolfier brothers in 1783. During the last 20 years they have made numerous experiments and substantial improvements. Captain Renard and other officers of the French army have constructed a fish shaped apparatus, and inflated it with hydrogen. It is driven by an electric motor of 8½ h.p., and has sufficient buoyancy to carry two aeronauts and all necessary accessories. In fair weather Captain Renard has succeeded in travelling at the rate of 12¼ miles per hour, in steering in any direction, and even in returning to his point of departure. The balloon, it is said, always keeps level, and so far there have not been any accidents; but no expedition has been attempted in wet or windy weather. Except that a more powerful motor, going at a higher speed, might be fitted to such an apparatus, Mr. Maxim thinks that it is as near perfection as is ever likely to be reached by a machine depending on aerial flotation. He proceeds to give an account of some experiments made by Prof. S. P. Langley, of the Smithsonian Institute, Washington, and of others by himself, to ascertain how much power is required to produce artificial flight by means of aero planes, after the manner of birds, and whether such power can be obtained without exceeding the weight which it would itself sustain. He says that heavy birds, with relatively small wings, carry about 150lb. per horse power exerted, and birds such as the albatross and vulture probably about 250lb. Prof. Langley, with small slanting planes was able to carry 250lb. per horse power exerted, and Mr. Maxim using heavier weights in proportion to plane area 133lb. per horse power, and using lighter ones, nearly the same as Prof. Langley. Mr. Maxim has lately devoted his energies to constructing a motor which should meet the requirements of the case, and has succeeded, he says, in producing one, a steam engine burning naphtha and with atmospheric condenser, within a total weight of 8lb. per horse power. He thinks, however,‡ that by using light naphtha and its vapour in the boiler instead of water, as well as in the furnace as fuel, a weight as low as 5lb. per horse power may be reached. Meanwhile Prof. Langley's ideas have been embodied in an experimental flying machine, a drawing and description of which will be found in the *Daily Graphic* for July 1, 1893. The body, which resembles that of a bird, and is 15ft. long, contains the propelling machinery in duplicate. The wings, which are 40ft. across, are of China silk spread on a tubular framework, stiffened with wire trusses. The boilers use liquid fuel, and contain a highly volatile fluid. The capabilities of the machine have not yet been practically tested. Promising as are the results hitherto obtained, they are as yet far from placing us on a level with birds in power to utilise the atmosphere as a navigating medium. The absolutely necessary power of delicate guiding, in rising, falling, and turning, whatever the direction or force of the wind, has yet to be considered and worked out. What would happen in case of a temporary breakdown of the aero-plane machinery we shudder to think of. An important step has been effected by the discovery that parachutes with tubular orifices at the top are comparatively safe appliances for descending to the earth from indefinitely high altitudes. Perhaps it may be arranged that each aeronaut should be able at a moment's warning to gird himself with one of these as with a life belt on board ship, and so descend in safety, or one or more automatically opening in case of disaster might be fitted to the aero plane as a whole.

† "*Progress in Aerial* Navigation," by Hiram S. Maxim, *Fortnightly Review, October, 1892.* ‡ *Engineer*, January 13, 1893, p. 28.

Eventual Exhaustion of Fuel Supply.

I have still to refer to one other question, the consideration of which must always give rise to very serious thoughts. We have seen that the decisive victories which in modern times man has gained over matter and over other animals, have been due to his use of power derived from other than animal sources. That power has invariably proceeded from the combustion and the destruction of fuel, the accumulations of which in the earth are necessarily limited. Mechanical appliances involving the consumption of fuel, have for a century at least been multiplying with alarming rapidity. Our minds have been set mainly on enlarging the uses and improving the [illegible] at all on economising the great sources of power in nature, which are now for the most part its fuels. Terrible waste of these valuable stores is daily going on in almost every department of use. Once exhausted they can never be replaced. They have been drawn upon to some extent for 1,000 years, and extensively for more than 100. Authorities say that another 1,000 years will exhaust all the more accessible supplies. But suppose they last 5,000 years, what then? Why, then, as far as we can at present see, our only motive powers will be wind and water and animals, and our only mode of transit sailing and rowing, driving, cycling, riding, and walking. Sir Robert Ball has estimated that in not less than 5,000,000 and not more than 10,000,000 years the sun will have become too cold to support life of any kind on this planet. Between the 5,000 years when fuel will certainly be exhausted and the 5,000,000 years when all life may be extinguished there will still be 4,995,000 years when, according to present appearances, man will have to give up his hardly earned victories over matter and other animals, and the latter will again surpass him, each in his own element, because he has no fuel.

Conclusion.

Leaving to our posterity these more remote troubles, we may, I think, justly draw from the entire discussion the conclusion that we have still a great deal to learn from mechanisms as they exist in nature. Great as have been the achievements of man since he first began to study mechanical science, with a view to directing the great sources of power in nature for his own use and convenience, the entire field of research is by no means yet fully exhausted. We must continue to study the same science with undiminished ardour. In so doing we shall do well to bear in mind that success can be achieved only by the patient, accurate, and conscientious observation of the great facts of nature, which are equally open to us all and waiting for our attention; and by drawing correct inferences therefrom, and by applying such inferences correctly to the fulfilment of the future needs and destiny of our race.

ELECTRIC LIGHTING IN CHELSEA.

By the courtesy of Mr. T. W. E. Higgens, surveyor to the Chelsea Vestry, we are enabled to place before our readers the following information, which is taken from Mr. Higgens's report to the Vestry for the year ending 25th March last:

Electric Lighting. The number of houses lighted by electricity in Chelsea was

	1890-1	1891-2	1892-3
Chelsea Electricity Supply Company	215	312	390
Cadogan Electric Light Company	16	18	–
London Electric Supply Corporation	2	2	—
	233	332	390

At the beginning of the year the Cadogan Electric Light Company was supplying electricity without an order. The St. Luke's Chelsea Electric Lighting Company had obtained an order, but had not satisfied the Board of Trade as to their financial position. The time for satisfying the Board of Trade having expired, the Vestry agreed to an extension of time, so as to enable the St. Luke's, Chelsea, Company (which appeared to be the Cadogan Company under another name) to satisfy the Board of Trade. They did not, however, do so, and as complaints were received of failure to supply light, the Board of Trade, after receiving a representation from the Vestry, cancelled the order, and the Chelsea Electricity Supply Company are now supplying the houses formerly supplied by the Cadogan Company.

As regards the cancelling of this order, I consider the action taken by the Board of Trade to be most satisfactory. It has always seemed to me to be a mistake to have allowed a private company, acting without statutory authority, to break up the public streets and supply electricity without proper supervision. It is true that the Cadogan Company entered into an agreement with the Vestry, and in virtue of that agreement they opened the streets; but that agreement did not enable the Vestry to control the company in their supply of electricity, and as a result of this absence of control great inconvenience was caused to most of the persons who obtained their current from this company.

When companies obtain statutory powers to open streets and supply electricity they are very justly, compelled to fulfil certain obligations in return for their privileges; but under their agreement with the Vestry (which was an illegal one) the Cadogan Company obtained privileges without corresponding obligations being enforced. This company, during some period of their existence, were supplying electricity at high pressure. The Board of Trade enforce certain restrictions and regulations upon any company which obtains an order or Act of Parliament before supplying

electricity, and their regulations as regards a high-pressure supply are of great value for the public safety, but as the Cadogan Company had no license order, or Act, no restrictions or regulations were enforced or could be enforced by the Board of Trade except as regards their overhead wires, and the Vestry had no means of knowing whether the supply of electricity by that company was at a constant voltage, whether it varied, or whether any attempt to regulate the supply was made.

Pressure Records. From time to time I have examined the records of pressure kept by the Chelsea Electricity Company. During the earlier portion of this year the pressure appeared to be very constant, but during the summer the recording ... the wire broke, and for some little time the record could not be kept with the usual accuracy; when, however, the wire was repaired, the pressure did not appear quite so regular, but towards the end of the autumn the pressure once more regained its regularity. The pressure record kept by this company is most satisfactory, arrangements are made to supply the consumers at as near 100 volts as possible, and there is seldom any appreciable variation of pressure.

Overhead Wires. -In June, 1892, I represented the Vestry at the Board of Trade enquiry as to the suggested by-laws for regulating overhead wires, and in October the by-laws were issued. Under these by-laws the persons owning wires are compelled to deliver to the local authority full particulars of all wires fixed by them within six months of the approval of the by-laws.

BUSINESS NOTES.

Great Horton.—An electric light installation is being put up at the Beckside Mills of Messrs. Joseph Benn and Sons, Great Horton.

Blackpool.—The central station is now in working order, and extensive use is made of electricity as an illuminant at the Winter Gardens.

Globe Telegraph and Trust Company.—An interim dividend of 3s. per share is announced on the preference and 1s. 6d. on the ordinary shares.

Swinton and Pendlebury.—The Local Board have referred to a committee of the whole Board the question of applying for a provisional order.

West India and Panama Telegraph Company.—The receipts for the two weeks ended September 15 were £323 less than for the corresponding period.

Brighton.—The Town Council have decided to light the Masonic Rooms at the Pavilion with electricity, provided that the Freemasons pay an increase of rent of £20 a year.

Croydon.—The Rural Sanitary Authority have granted permission to the National Telephone Company to erect poles on the sewage farm at Merton to support telephone wires.

Eastern Extension, Australasia, and China Telegraph Company.—The Directors have declared an interim dividend for the quarter ended June 30 last of 2s. 6d. per share, free of income tax.

Blackburn.—The Corporation, as will be seen from our advertisement columns, invite tenders for the supply and erection of boilers, dynamos, cranes, cables, conduits, accumulators, switchboards, etc.

Mumbles.—The Mumbles Local Board are considering the advisability of introducing electric lighting in the village, and Mr. J. Stansfield Brun, C.E., surveyor, has been instructed to draw up a report on the subject.

Joined in Parallel.—We are informed that on the 13th inst. the marriage took place, at Grafton-square Church, Clapham, of Mr. W. J. Fryer, A.I.E.E. (Messrs. Graham and Baddle, Oxford street), and Miss Maggie Nyren.

Western and Brazilian Telegraph Company.—The traffic receipts for the week ended September 15, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £1,220.

Warminster.—The chairman of the Local Board, in reply to a question at a meeting last week, said that he hoped to be in a position to report something definite with regard to the introduction of the electric light by the next meeting.

City and South London Railway Company.—The receipts for the week ending September 17 were £756, against £744 for the same period last year, or an increase of £12. The total receipts for the second half year of 1893 show an increase of £440 over those for the corresponding period of 1892.

Harrogate.—A letter was read at a meeting of the Town Council last week from Mr. Priestly, of Halifax, with regard to a refuse destructor to be used in the raising of steam in connection with the electric lighting installation. The letter was referred to the General Purposes Committee.

Telegraphic Communication Restored.—The Western and Brazilian Telegraph Company, Limited, announce that the Brazilian Government have withdrawn their restriction as to the sending of telegrams, but messages must be in plain language and in no way refer to the state of affairs in Brazil.

Personal.—We understand that Mr. C. A. Hemingway, who for the last seven years has been in the employ of Messrs. Drake and Gorham, electrical engineers, 66, Victoria-street, Westminster, has now severed his connection with the above firm, and has commenced business as electrical engineer at 10, Petersham-road, Richmond, Surrey.

Maidstone.—At a meeting of the Local Board last week Mr. Barker asked what had become of the electric lighting question. The Town Clerk replied that a meeting of the committee would be held very shortly; it had stood over owing to the absence of various members. The question had been referred to a committee of the whole Board.

Hope-Jones Electric Organ Company.—A concert was given last week at Birkenhead by Mr. Robert Hope-Jones to the workmen of the Company and friends. In an interval Mr. Hope-Jones mentioned that 12 months ago 16 men did the work of the firm, that now there were 100 men engaged, and that there was work sufficient for twice that number.

Universal Lathe.—Messrs. Lotz, Abbott, and Co., of 144, High Holborn, W.C., inform us that they have been appointed the sole selling agents for Great Britain, the Colonies, and also for the United States of America, for the sale of the Pittler's universal lathe. Various styles and sizes of these machines in practical operation may be seen at the above address.

Wolverhampton.—Alderman W. H. Jones formally introduced the electrical engineer to the Council at a meeting of the latter last week. The committee, he observed, were anxious to perfect their scheme and as soon as possible bring the matter before the Council. The delay had been owing to the fact that the engineer could not get to Wolverhampton until the termination of his three months' notice.

Cork.—The Corporation have referred to the Law and Finance Committee a letter from Mr. Robert Starke, convener of the Telephone Committee of the Glasgow Corporation, relating to the telephonic system, and requesting the attention of the Council thereto, in view of its pressing importance to corporations. The primary object was to get the telephone system into the hands of corporations, and not private companies.

Gillingham (Kent).—When the members of the Local Board met last week, several of them complained of the bad light from the gas lamps in the street. Mr. Beveridge said it would be a good thing when they got the electric light at Gillingham and had a little opposition. It seemed to be no use complaining to the gas company. The Chairman said that they could not help it, and that he wished they had the electric light.

St. Pancras.—The Vestry have sanctioned extensions of the electric lighting station by the addition of three 90-unit engines and dynamos and three boilers at the existing Regent's Park station, with another sub-station in Regent's Park road. These extensions will enable to be served a further 5,000 16-c.p. lamps installed. It has also been decided to construct a second station, in combination with a refuse destructor, in King's road.

Govan.—At a meeting of the Govan District Lunacy Board, Mr. Findlay, in moving the adoption of the Building Committee's minutes, referred to the report by an expert on lighting the Hawkhead Asylum with electricity, which stated that the installation would cost £5,300, and that the yearly upkeep would amount to £269. Mr. Findlay suggested that the whole matter should be referred back to the committee, which was agreed to.

Derby.—The House Committee of the Board of Guardians recommended, at a meeting of the latter on Tuesday, that an expert should be employed to report to what use a steam engine now standing idle at the workhouse could be put, his fee not to exceed five guineas. The Rev. H. R. Roll said it was thought the engine might be utilised for the purpose of supplying the workhouse with electric light. The matter was referred back to the committee.

Newtown.—The Newtown and Llanllwchairn Local Board met last week, and it was mentioned that the Street Lighting Committee had decided to adjourn the question of lighting the town by electricity for six months. The Chairman said that they had had a long report from Messrs. Tozer and Rooper as to supplying the town with electric light, which would cost a little less than gas, and the town would reap many advantages if they adopted electric lighting.

New Issue.—The National Electric Supply Company, Limited, invite applications for a portion of an issue of £20,000 of debentures, bearing interest at the rate of 4½ per cent., payable on September 1 and March 1, for which coupons payable to bearer are attached. The debentures are repayable at par on September 1, 1900. These debentures are a first charge upon the entire property and undertaking of the company, secured by deed to trustees for the benefit of the debenture holders.

Dorchester.—The Town Clerk mentioned at a meeting of the Council on the 15th inst. that he had received Messrs. Newton's report upon the electric lighting of the town, but he thought it had better go to committee. This course was agreed to and the Council there and then resolved themselves into committee to receive the report. Eventually however, it was decided not to hear the report read then, but to have it printed and a copy sent to each member of the Council for perusal.

Haddon Hall.—We understand that Messrs. Drake and Gorham were entrusted with the lighting arrangements in connection with the recent Primrose League demonstration of the Bakewell and other local habitations at Haddon Hall, the historic seat of the Duke of Rutland, and that the effect produced by four Crompton-Pochin arc lamps was extremely good. Very short notice was given for the carrying out of the work, but notwithstanding this everything passed off highly satisfactorily.

Leeds.—The Parliamentary Committee of the Leeds Corporation considered on the 15th inst. the proposal of the Government to take over the trunk lines of the National Telephone Company. Communications on the subject were read from Glasgow, and also

from the Manchester Guardian Society for the Protection of Trade. It was resolved to write to the members for the city, along with the member for the Pudsey division, asking them to keep a watch on the pending negotiations in the interests of the districts.

Lighting at Lambeth.—A letter was read from Mr. W. H. Preece at a meeting of the Board of Guardians on the 13th inst., stating that two boilers would be required for the electric lighting scheme for the workhouse and infirmary, and the details of which were given in our issue of the 8th inst. He estimated their cost at £800. Mr. Pialcox withdrew his motion with reference to supplying Mr. Stacey Gold with a copy of the minutes and agenda in order that he might obtain further information regarding the practice of other unions. The Board agreed to postpone its consideration.

Lighting at Pontypool.—The use of the electric light is extending in this town. The shops of Messrs. W. Pegler and Son and Mr. J. Daniel are effectively lighted by electricity, while Mr. Hall, of The Ship, lights a considerable part of Crane street by a powerful lamp placed over the entrance to his hotel. The illuminant seems in a fair way of coming into general use, both for shops and private houses. The improvement in the lighting of the drapers' shops is very marked, and Messrs. E. Fowler, R. W. Wooley, and E. Jones have all been most liberal in the use of a large number of 200 c.p. lamps.

Yarmouth.—The Town Clerk mentioned at a meeting of the Council last week, that the Local Government Board, prior to sanctioning the loan asked for by the Council for the purpose of electric lighting, required that the site upon which it was proposed to erect the buildings should be vested in the urban authority. The Finance Committee recommended the Council to grant to the urban authority, for the purpose of an electric light station, a piece of land on the east side of the Southgate road, measuring 140ft. from north to south and 100ft. from east to west. The recommendation was adopted.

Leamington.—At a meeting of the Town Council last week Alderman Gilbert enquired why the sub-committee had not met to consider the question of telephonic communication. Mr. Passman replied that the committee had not been called together because everyone had been taking his holidays. He then read letters he had received from Mr. Bezant and the manager of the telephone company as to connecting the corporate offices, etc., with the exchange. Alderman Gilbert moved that the letters be referred to the telephonic sub-committee. The sub-committee was to meet on the 14th inst. to consider the matter.

Newcastle-on-Tyne.—The Tyne Improvement Commissioners have agreed to light the Commissioners' offices by electricity, and Messrs. Temple, Stout, and Green have been appointed a sub-committee to carry out the arrangements. Messrs. C. A. Parsons and Co. have issued a pamphlet dealing with installations carried out by them. It is illustrated by means of Meisenbach blocks, and has fine plates of the exterior of the Central railway station, Newcastle, showing the electric lamps there; a view of the works of the Newcastle and District Lighting Company, Forth Banks, and the electric lighting station at Cambridge.

Camborne.—An electric light installation has been put up at the works of Messrs. Holman Bros., the well-known ironfounders and rock drill specialists, at Camborne. This firm is the first in the town to take the initiative in laying down an installation for illuminating purposes, and it is, with the exception of Dolcoath Mine, the first in the neighbourhood. The installation consists of 46 Edison-Swan incandescent lamps, and several Crompton arc lamps ranging from 2,000 c.p. to 500 c.p. A Crompton dynamo is used, driven by a two-cylinder engine made by Holman Bros. The installation has been carried out by Messrs. Veale and Co., Limited, of St. Austell.

Cambridge.—The Guildhall and Building Committee of the Town Council reported at a meeting of the latter on the 14th inst. that they had invited estimates from two local firms for the installation of the electric light in that portion of the Guildhall comprising the small assembly room, the alderman's parlour, and the exit to Peas hill. Tenders had been received from both firms, and the committee recommended the Council to accept that of Messrs. Medhurst (now Messrs. Russell and Co.), at £37. 5s., subject to a slight alteration in the lamps to be used in the small room and alderman's parlour, which would entail an additional cost not exceeding £5. Councillor Bell moved and Alderman Whitmore seconded, the adoption of the report, which was carried.

Edinburgh.—At a meeting of the Town Council last week, Bailie Macpherson moved the acceptance of estimates for work in connection with the new public baths to be erected at Caledonian crescent, Dalry. He said an idea had suggested itself in view of the fact that there was found to be a surplus of steam at the Powderhall destructor. As the Council was aware, the intention was to have a destructor also in the Dalry district, and he now proposed that when they were erecting the new baths at Caledonian crescent they ought to give instructions for wires to be put through the establishment, so that when the destructor was built they might utilise the surplus steam from it in the lighting of the baths by electricity. No extra cost would be involved. The estimates were accepted.

Dundee.—At the monthly meeting, on the 14th inst., of the Police Commission, reference was made by Mr. Brownlee to a minute of a sub-committee of the Lighting Committee recommending the erection of 36 electric lamps in the central streets of the city, provided that the Gas Commissioners would supply the light to the lamps at £20 each. Mr. Brownlee pointed out that by adopting the minute the Commission committed itself to an expenditure involving a very large capital outlay. The addition of the lamps meant an expenditure of between £6,000 and £7,000. The Clerk explained that the whole work was to be done at once, but the cost was to be spread over three years. Mr. Ritchie said that unless they were prepared to face the expenditure for a permanency there was no use of going on. The minute was approved.

Huddersfield.—The electric lighting scheme of the Corporation originally provided for the supply of electrical energy for the purpose of illumination to the central business part of the town. In consequence of the demands for supplies to residences in the Edgerton district, mains by which the energy will be conveyed are being laid. When completed, the extension will cover a lineal measurement of about two miles, a considerable number of the large residential establishments receiving installations. The Town Hall has been equipped with the electric light, and it is estimated that the total cost of this improvement and the redecoration will be about £1,500. Messrs. Mather and Platt, of Victoria street, Westminster, have put in the electrical fittings under the direction of Mr. A. B. Mountain, the borough electrical engineer. The number of lamps fixed is about 750, equivalent to 2,200 lights of 8 c.p. The current is obtained from a special transformer station in the basement of the Corporation offices.

New Electric Pumping Plant.—A set of new electric pumping plant has been constructed for the Shilbottle Colliery by Messrs. Ernest Scott and Mountain, Limited, of Newcastle, and on Saturday the plant was tested at the company's works. The plant is capable of delivering 200 gallons of water per minute against a head of 185ft. The dynamo is of the improved "Tyne" type, shunt wound, and constructed to give an output of 50 amperes at an E.M.F. of 500 volts when running at a speed of approximately 700 revolutions per minute. It is fitted with gunmetal protection guards over the armature, in order to prevent any dust or dirt getting to the armature whilst running. The conducting cables consist of 1,232 yards of concentric cable. The pumps are of the three-throw type, capable of delivering 200 gallons of water per minute against a head of 185ft., and are driven by a 25 h.p. Tyne electric motor. The power from the motor is transmitted to the pumps by means of a belt driving on to a countershaft which is geared into the crankshaft. A large number of engineers witnessed the test, which was satisfactory.

Salford.—On Tuesday Mr. S. J. Smith, C.E., Local Government Board inspector, held an enquiry relating to an application by the Salford Corporation for authority to borrow £50,000 for the purpose of electric lighting. The Town Clerk explained that the Corporation were empowered by the Salford Electric Lighting Order, 1890, and the Confirming Act to supply an electric engine within the borough, and to secure land and do other matters incidental upon such supply. The Corporation had accordingly secured a piece of land fronting Walness road for £2,774. It was not proposed to proceed with the entire scheme at once, but it was intended to expend only £32,000 of the £50,000 applied for in the initial operations. The scheme affected the entire borough, and it was anticipated that it could be carried into effect within six months of the date on which sanction was given. A period of 20 years would be requested for the repayment of the loans. Mr. Edward Manville, M.I.C.E., electrical engineer to the Corporation, gave evidence as to the details of the alternating-current system, which it is proposed to adopt.

Paignton.—Two letters from electrical engineers, offering to light the town by electricity, were read at a meeting of the Local Board on Monday. A London firm wrote: "Hearing that your good townspeople are contemplating lighting your rapidly increasing and attractive town with electric light, I shall esteem it a favour if you would kindly give me any particulars in respect of same, also whether the Corporation would be inclined to entertain a scheme for running electric launches or ferry boats to and from Torquay during the summer." Messrs. Samuel Williams and Co., Cardiff, enquired if the Board was in a position to go into the question of electric lighting; if so, in return for the concession, they were prepared to provide and work the necessary plant. Mr. Bridgman pointed out that Paignton was behind little American villages in this matter. Surely Paignton ought not to remain behind the times. He moved that a committee be appointed to enquire into the subject and report. There was no reason why, if people dangled these offers before them, they should not have a nibble. Mr. Parnell pointed out that an electric light committee already existed. The letters were referred to the committee.

Lighting at Taunton.—The Watch, Lighting, and General Purposes Committee of the Town Council at a meeting on the 12th inst., stated that they had ordered the electrical engineer to be instructed to report to every meeting of the committee. The committee had instructed the surveyor to erect a new office at the electric lighting works, using old materials as much as possible. The committee recommended that the following assistants be appointed: Messrs. Couzens, Phillips, and Thornhill, at the respective salaries of £70, £60, and £40, subject to one month's notice on either side, and Witham without salary for six months. They also recommended that the pupils be articled to the Council, that the engineer be paid quarterly his proportion of the premiums, and that Mr. Alfred Ernest Witham be retained at his present salary of £30 a year to collect meter rents and other income connected with the electric lighting, and to keep the books connected with the business department thereof. The committee had arranged for Dr. Fleming to visit Taunton during the present month. The committee recommended that underground wires should be laid along Billet street to Salisbury House. Councillor Potter moved the adoption of the report, and Alderman Van Trump seconded. Councillor Westlake proposed that the question of laying underground wires along Billet-street should be

referred back to the committee, and Councillor Vile seconded. He remarked that it would be a bad principle to undertake the work unless they knew what income would be derived from it. After further discussion, the amendment was put and carried by ten to seven. The rest of the report was adopted.

The Ealing Tenders.—The following list shows the tenders sent in for wiring the public buildings:

Binko and Co.	£684
Brown and Co.	700
Spagnoletti and Co.	793
Paterson and Cooper (accepted)	795
Taylor, Smith, and Co.	842
Emanuell and Sons	853
Lund Bros.	871
Howard and Co.	875
R. A. Scott	903
Brush Company	920
Phipps and Co.	990
Rawlings Bros.	1,020
Johnson and Phillips	1,099
British Electric Company	1,119
Nicholson and Tyler	1,125
Thomas Digby	1,130
Sax and Co.	1,149
Baily and Grundy	1,188
MacClellan and Co.	1,249
R. Dawson	1,252
Crompton and Co.	1,259
Strode and Co.	1,277
S. Cutler and Sons	1,362
B. Verity and Sons	1,376
W. Mackie	1,611
Tickner	2,187

Rockhampton Gas and Coke Company, Limited.—The report of the Directors for the half year ended June 30, 1893, states that, taking everything into consideration, the Directors have reason to congratulate the shareholders upon the satisfactory results of the past half year. The gas operations show a profit of £1,940. 14s. 9d. The electric light operations show an actual loss of £115. 15s. 5d., to which is added £289. 13s. 7d. interest upon the capital involved in the electric light plant and buildings, etc., making a debit balance in all of £414. 9s. The net profit for the whole of the Company's business is, therefore, £1,526. 5s. 9d. A great improvement appears in the electric light revenue as compared with that of the preceding half year, while the working expenses are much reduced. The number of customers for the light is increasing, and public lighting with high power arc lamps will be inaugurated on the Fitzroy Bridge in the course of a few months. In view of the large sum vested in the gas interests, the Directors have thought it inadvisable to push the electric lighting operations, but have preferred to allow this portion of the Company's business to expand on its own merits and in response only to unsolicited applications for the light. The Directors anticipate being able to report an actual profit upon the electrical business at the next meeting of shareholders. The gas consumption for the half year is slightly below that of the corresponding period of last year, but every attention is being directed to the extension of this section of the Company's business, and particularly in those outside and scattered districts where the gas-mains are already laid but, comparatively speaking, little used. Special concessions will be made in such districts to induce the residents to become consumers of gas. The Directors recommend the payment of a dividend at the rate of 10 per cent. per annum, amounting to £1,721. 18s. 2d., which will necessitate the appropriation of £200 of the reserve fund for equalisation of dividends.

Lighting at Wakefield.—The members of the Town Council last week discussed the question as to whether or not an application should be made to the Board of Trade for a provisional order under the Electric Lighting Act, authorising the Corporation to supply electricity. The Mayor (Councillor J. S. Booth) presided. Councillor W. Moorhouse, in proposing that a provisional order be applied for, said that as the public lighting of the city was at present under the control of the Sanitary Committee it was perhaps desirable that he should make one or two observations in moving that resolution. In January of the present year a special sub committee was appointed to consider the advisability of adopting the electric light in the city, and, acting on instructions given at a meeting in February, many enquiries were made from other corporations who had carried out electricity works, and others who contemplated doing so, with the result that in May the Council, by a unanimous vote, empowered the town clerk to take the necessary legal steps for securing a provisional order. In preparing that provisional order it was found that the services of an electrician were required, and as the time had arrived when it was necessary that a full and special report should be prepared by a specialist to guide the committee in deciding upon the best system to adopt, it was thought best to at once appoint a consulting electrical engineer. Mr. Hammond, of London, who was appointed at the Council meeting on Tuesday night, had had an interview with a committee of the whole Council, and the members were favourably impressed with the knowledge he possessed of the subject. As he (Mr. Moorhouse) had stated before in that Council chamber, he firmly believed the electric light would be the light of the future, and they would fail in their duty if they did not introduce it to the citizens of Wakefield at the present time. There could be no doubt that every year the Legislature was imposing new duties upon local authorities, with the result that local taxation was beginning to weigh rather heavily, and in his opinion if they were to continue in the path of progress it could only be done in face of the present monopolies by securing the electric light. He thoroughly believed there would be a demand for it, and that it would eventually be a source of revenue to the Corporation. It was evident the Council had now arrived at that period when they must decide the question either one way or the other. There was a demand for electricity in the town, as a private company had already applied for the right to supply. The County Council, he understood, had decided to light their new offices with it. If the Council pushed on their works with energy, perhaps they might be able to supply it if the resolution was carried. There was no doubt that in the past corporations who had had the control of the water and gas supplies had made profits which gave enormous relief to the rates, and those corporations who did not possess them might well look on with envy. Wakefield had now another chance, and he did hope for the sake of the town the Corporation would not let that opportunity pass by. It was well known that the gaslight had been a very successful undertaking financially in Wakefield, and the success of the gas industry was in his judgment, but an imitation of the success of the electric light in the future. There could be no two opinions about the merits of the two lights, and provided electricity could be supplied at the same rate as gas, which most assuredly it would be in the future, he ventured to assert that 90 out of every 100 persons would prefer the electric light, not only because of its brilliancy, but because it was less detrimental to health and did not do the damage to decorations and stock in trade that gas did. There could be no doubt that from the mere fact that the electric light did not produce heat, it was much better on that ground alone for lighting up public buildings, churches and private workshops, and offices of any sort. If the Council should pass his resolution that night, the provisional order would be applied for during the next month (October) and then it would come into force in June or July of next year, from which period two years would be allowed by the Board of Trade in which to erect the works. Councillor Smith seconded the resolution, and, after the matter had been fully discussed, the resolution was put to the meeting and was adopted.

The Tramway Question at Halifax.—In our last issue we briefly referred to the decision of the Town Council regarding the proposed introduction of electric tramways in that town, and as the matter is of considerable importance, we have no hesitation in amplifying as follows the paragraph given last week. It appears that a controversy had arisen on this matter through a recommendation to the Council by the Board of Works Committee to accept the terms of a company for the introduction of electric tramways. The Mayor (Alderman James Booth), who presided at the meeting, suggested that the first matter the members should consider was whether it was desirable to have tramways in the town. If they decided in the affirmative, then they might debate the other questions arising out of the subject. Councillor W. H. Spencer said that although perhaps many members were in favour of tramways being laid in Halifax, they were opposed to them at the present, not having a desire to unduly load the rates. Speaking for himself, he was opposed to the scheme that had been mentioned. Councillor H. E. Greenwood moved a resolution to the effect that the time had not arrived when it was desirable to have tramways constructed in the borough. He said no request had been made for them by any of the burgesses, and such a demand ought to be made, because they would have to pay the cost in the first instance. In the second place, there were no streets in the town where any kind of tramways could be laid down with advantage. Then there had just been introduced a system of penny 'buses, which the public appreciated. He thought the system, which was highly satisfactory, answered all the needs of the present. He should like to see these tried further before the Council took any step either towards expenditure on tramways or to the granting of a lease to a private company, but he should be opposed to the granting of a lease to any private company. Councillor Maude seconded the proposition. He favoured the idea that it would be best for the Corporation to take the tramway question in hand whenever brought forward. Probably in two or three years the Corporation would be in a much better position to consider it. The Town Clerk suggested, in place of the resolution, the words: "That the question of introducing tramways into Halifax be adjourned *sine die*." This suggestion was adopted. The Town Clerk, in reply to Councillor Maude, said it should be distinctly understood that, even if the Corporation decided itself to introduce tramways, they could not legally work them without a special Act of Parliament. In answer to Councillor Wade, the Town Clerk replied that the Leeds Corporation had obtained these special powers to take over the tramways in their city. Councillor Davenport asked if the same course had been adopted in Huddersfield. The Town Clerk answered that he did not know what other towns had done, but without the consent of a Corporation no company could introduce tramways into any town. Assuming that the Corporation allowed a company to come into Halifax, the Act gave them power, after the expiration of 21 years, to purchase the tramways at a valuation if they gave six months' notice; if they neglected to give the necessary notice, then they would have to wait seven years more before they could give a similar notice, and so on. Councillor Spencer was very glad the subject was to be left in the mystery that shrouded it. They felt relieved from the fact that the vice chairman of the Board of Works Committee, who was one of the sub commitee from whom the resolution came, now opposed the introduction of the tramways. He (the speaker) only wanted to dissent to one remark with regard to the financial aspect of the question. They could raise the whole of the money easily if they desired to do so. He thought the resolution should express the

desirability of having municipal tramway lines, to be laid from time to time as the requirements developed, and to be leased to companies in accordance with the terms mentioned by the town clerk. But as regarded the overhead trolley system, he was utterly opposed to it on several grounds. In the first place it was a disfigurement to a town, and then he considered the system was certain financial failure to whoever undertook it, owing to the quarrels it led to with other electrical concerns, such as telephones and telegraphs. He wished the resolution that expressed the opinion of the Council that it was desirable to lay municipal tramways to be leased, but that at the present time it was inexpedient for the borough to enter upon an undertaking, though not upon the ground of their being unable to raise the money. Alderman Tattersall moved as an amendment "That in the opinion of the Council the construction of an efficient tramway system is desirable as soon as the finances of the borough will admit of it being done, and that such tramways when constructed should be under the control of the Corporation." Geographically the town was badly situated for the adoption of a tramway system, and the streets were altogether unfavourable. In any case he was opposed to the Corporation, after allowing a private company to step in, waiting till its term expired before the system could be bought by the town, and that probably at enormous cost. But he did not think a move in this direction at all necessary at present. A few years would alter things. A number of county borough councils were taking over existing tramways hitherto worked by private companies, and they had an illustration of the great cost of the process in what the Leeds people were having to pay. When it was possible to have a tramway system in Halifax, then the most sensible policy would be for the Council to construct the same, obtaining powers to work it by Act of Parliament. Tramways were ostensibly for the convenience of the public. If the concern paid, the public would then reap the benefits; if not, then they ought to bear the loss. Councillor Lister seconded the amendment, for the reason that he considered if a tramway system were introduced into Halifax, it should be not only owned but also controlled and worked by the Corporation. He was also of opinion that the present time was not a time when the Corporation ought to embark upon a large enterprise of this kind. The Bradford Corporation had been considering the question very carefully of laying down and working an electric tramway on the Wakefield road, and in view of that they had made an experiment not long ago on the tramway between Foster square and the Grammar School. He had some conversation with the deputy town clerk, who informed him that the cost was very excessive indeed, and that if the overhead trolley system were adopted, the annual loss to the borough was estimated by the borough engineer at about £845, while if the conduit system were adopted, the loss would be about £1,100 per year. It would be wise to defer the consideration of the question, because in the course of a few years they might see electrical science in its application to tramways brought to a more perfect state than it was at present, and made to work in a more economical manner. Councillor Maude said he did not see the importance of Alderman Tattersall's amendment, because it bound the future Town Council, who might decide otherwise than according to this amendment. The proposition left it an open matter with a future Council. Councillor Butler supported the motion. They had had before them, and would have again shortly, the question of electric lighting, and it was a fact, he believed, that when tramways and electric lighting were adopted in one borough, the two systems were materially benefited. Councillor Woodhead supported the motion. He could have accepted Alderman Tattersall's amendment but for the fact that it pledged to some extent a future Council, and that he thought was undesirable. Further, there was scarcely a through street in which tramways could run. One or two corners, notably the White Hart and George-street, wanted widening before a tramway scheme was adopted. It was also desirable to see the development of the electric lighting scheme before any action in this direction was taken. Eventually the amendment was rejected, and the resolution was adopted, as mentioned last week.

PROVISIONAL PATENTS, 1893.

SEPTEMBER 11.

17025. **Improvements in raising and lowering the light of electric glow lamps.** Thomas Bedworth Sharp, County chambers, Martineau street, Birmingham.

17030. **Improvements in apparatus for facilitating the erection or fastening of electrical conductors in wood casings.** Gerald St. John Day and William Henry Wheeler, 64, Barton arcade, Manchester.

17045. **Improvements in or relating to electric clocks, part of such invention being also applicable for other purposes.** John Henry Gash and Joe Skinbeck, 323, High Holborn, London.

17052. **Improvements in arc electric lamps.** William James Davy, 161, Huddleston road, Tufnell park, London.

SEPTEMBER 12.

17093. **Improvements in or relating to electric telephones.** Thomas Sloper, 14, Brittox, Devizes.

17127. **Improvements in electrolytic cells.** Thomas Craney, 45, Southampton buildings, Chancery-lane, London. *(Complete specification.)*

17175. ***Improvements in or relating to electric telephones and microphones.*** *Thomas Sloper, 11, Brittox, Devizes.*

SEPTEMBER 13.

17172. **Improvements in air and water tight covers for junction-boxes used in electrical distribution and for other purposes.** Sydney William Baynes, 37, Spring gardens, Manningham, Bradford.

17189. **Improvements in electric switches.** John Macintosh Mackay Munro and James McFarlane, 151, St. Vincent-street, Glasgow.

17197. **Improvements in dynamo-electric machinery.** Rookes Evelyn Bell Crompton and Sydney Linton Brunton, 55, Chancery lane, London.

17220. **Improved methods of recovering zinc from the waste products of galvanic batteries.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop road, Balham, London. (Complete specification.)

17221. **New or improved galvanic batteries.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop-road, Balham, London. (Complete specification.)

17234. **Improvements in electric switches for series circuits.** Albert Augustus Goldston, 4, South street, Finsbury, London.

SEPTEMBER 14.

17310. **Improvements in contact apparatus for receiving currents from overhead conductors on electric railways.** Siemens Bros. and Co. Limited, 28, Southampton-buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

17330. **Improvements in holders for incandescent electric lamps.** John Wigham Edmundson and Frederick James Satchwell, 46, Lincoln's-inn fields, London.

SEPTEMBER 15.

17341. **Improvements in alternate-current dynamos.** Gisbert Kapp, 70, Market street, Manchester.

17348. **Improvements in electrical transformer street surface boxes.** Henry White Bowden and William Boby, 16, Union court, Old Broad street, London.

17352. **Improvements in electrically controlled arc lamps.** Frederick Thomas Schmidt, 9, Clarendon street, Bradford.

17372. **Improvements in magneto-electric motors.** Henry Ludeke, Ernest Louis August Ludeke, Arthur James Thorman, Ernest de Bunsen, and Edward Madge Hore, 4, St. Benet place, Gracechurch-street, London.

SEPTEMBER 16.

17445. **Improvements in pipe conduits for electric mains.** William Harding Scott, Gothic Works, King street, Norwich.

17466. **Improvements in the treatment of zinc produced by electrolysis.** William Wright and John Brumfield Hamond, 1, Quality-court, Chancery-lane, London.

17493. **Improvements relating to thermo-electric batteries and to apparatus for use in the manufacture of the same.** Jean Baptiste Charles Dion, 45, Southampton buildings, Chancery lane, London.

SPECIFICATIONS PUBLISHED.

1892.

15318. **Electrical transformers.** Leigh. (Apollonj.)

15137. **Electrical contacts.** Gray and Price.

15689. **Relays for electric telegraphs.** Willot.

16768. **Switching telephone, etc., exchanges.** Pippette.

17092. **Insulating and supporting electric wires.** Crompton and Dowsing.

18847. **Field magnets and armatures of current electro-motors, etc.** Joel.

18994. **Electromagnets.** Timmis.

1893.

7848. **Indicating telegraphic messages.** Levi.

14210. **Telegraph posts, etc.** Siemens Bros. and Co., Limited, and May.

NOTES.

New Boat.—An aluminium ferry-boat has been launched at the Quai d'Orsay, Paris.

Telephony.—Various subscribers to the telephone in Glasgow are complaining of the cross-talk on the lines.

Dirigible Torpedoes.—Experiments are to be made next month by the Royal Engineers with the Brennan dirigible torpedo.

Cheap Current.—Current is now being supplied for motive power purposes from the Cologne municipal station at 3d. per 1,000 watt hours.

Obituary.—The death has just taken place at Folkestone of Mr. Henry Weaver, the managing director of the Anglo American Telegraph Company.

Madras Tramways.—An extension in the time for constructing the electric tramway has been granted. A local board of directors is to be appointed.

Lighthouse.—Mr. Passmore Edwards has intimated his intention of erecting a lighthouse on the St. Agnes Beacon, which will be lighted by electricity.

Danzic.—The General Electricity Company, of Berlin, have entered into a provisional agreement for the working by electricity of the five tram lines in this town.

Branch Societies.—Proposals are under consideration in the United States for the establishment of branch societies of the American Institution of Electrical Engineers.

Siam.—The Siamese Government Telegraph Department has profited greatly by the abundance of the telegraphic messages recently sent between Paris and Bangkok.

Lightning.—The parish church of Misson, on the boundary of the county of Nottingham, was struck by lightning on Saturday, and a great portion of it was completely destroyed.

British Association.—The meeting next year will be held at Oxford, and not at Ispwich, as mentioned in our last issue. The meeting in 1895 will, however, take place at the latter town.

Cardiff.—Councillor Jenkins suggests that the Town Council should acquire the tramways. If the proposal is entertained, the municipality might be disposed to consider electric traction.

Society of Engineers.—The next ordinary meeting will be held at the Town Hall, Westminster, on Monday next, when a paper will be read on "Gas Substitutes" by Prof. Vivian B. Lewes, F.I.C.

The Douglas Tramway.—This electric tramway, to which reference was made in a recent issue, has been started as far as Crowdle Glen. It will eventually be extended to Laxey, a distance of seven miles.

Traction in Vienna.—The Austrian Ministry of Commerce have been approached by the General Electricity Company, of Berlin, with a view to undertaking preliminary technical steps with regard to several electric lines in Vienna.

False Fire Alarms.—Notwithstanding the fact that Parliament has recently given magistrates the power to fine any person giving a false alarm to the firemen the heavy sum of £20, false "calls," by means of the alarm posts, continue to be given in London with great persistency.

Light Electric Vehicles.—Experiments are being made in Italy with light electric vehicles somewhat larger than ordinary tricycles. The vehicles are equipped with a battery of 10 cells weighing about 3cwt., and capable of yielding sufficient energy to propel them for from three to five hours.

The "Nile."—This new Royal Mail steamer is lighted by electricity. The generating plant is in duplicate, there being two high-pressure engines coupled direct to dynamos running at 210 revolutions and giving a current of 165 amperes at 100 volts. There are 500 lamps installed in the ship.

Antwerp.—The work in connection with lighting the town by electricity has commenced. A London company have secured the contract for laying about 11 miles of mains, and a staff of English engineers is superintending the laying of the mains. It is calculated that about six months will be required to complete the contract.

The Proposed Berlin Electric Railways.—It is stated that the Imperial Government has approved of the schemes prepared by Messrs. Siemens and Halske for the construction of three elevated electric lines in Berlin. The gauge will be 4ft. 8½in., and the cars will be mounted on two trucks, each being equipped with an electric motor.

Southampton.—The docks have just been equipped with an electric light installation for the London and South-Western Railway Company. The low-tension system has been adopted in conjunction with accumulators, the current being distributed by means of feeders to a three-wire system of mains. Both arc and incandescent lamps are used.

Traction at Wolverton.—Electric traction engineers should bear in mind the Wolverton and Stony Stratford District New Tramways Company, Limited, which has been registered with a capital of £5,000 in £100 shares, to acquire the undertaking of the Wolverton and Stony Stratford and District Tramways Company, and to extend its operations.

Science and Farming.—Lord Rayleigh has notified the villagers in the immediate neighbourhood of his Essex seat, Terling Place, near Chelmsford, that anyone wishing to hire land for farming purposes can have from one to four acres, at 25s. per acre. The usual price per acre for the hire of allotment land in Essex ranges from £2 to £4 and in some cases to as much as £6 per acre.

The Tramways Institute.—Mr. J. G. B. Elliot, the secretary of the Tramways Institute of Great Britain and Ireland, informs us that the meeting proposed to be held at the Isle of Man on the 4th and 5th October has been abandoned in consequence of the very small number of members who would be able to attend. There will, therefore, be no general meeting of the institute that month.

Cheaper Telephony Wanted. — The Sonneberg Chamber of Commerce, supported by other similar institutions, has approached the German postal authorities with a view to getting reduced the annual subscription to the telephone. In reply, Herr von Stephan has intimated that, instead of being able to grant a reduction, an increase in the rates may be expected, at least for inter-town communication.

Train-Lighting.—A welcome improvement is being introduced on the carriages of the District Railway. Instead of the one ordinary gas lamp in the centre of the roof of each compartment, there are being installed four incandescent lights fixed in the four corners of the compartment immediately over the passengers' heads. An experiment has previously been made with the electric light, which is very satisfactory.

Railway-Office Lighting. — The Great Northern Railway Company on Saturday evening introduced the

electric light for the first time in connection with all the departments at King's Cross. There are altogether 144 offices which have been electrically equipped. The work of lighting Holloway and Finsbury Park Stations is being rapidly pushed forward, and is expected to be brought to completion in a few weeks.

Coast Communication.—The Post Office authorities have decided, and the work is now in progress, to lay a cable from the Gunfleet Lighthouse to the old Gapway at Frinton, near Walton-on-the-Naze, as the first portion of the telephonic communication between the various lighthouses and vessels on the east coast and the coastguard stations at Harwich, Walton, and Clacton, all three of which will be connected by a land wire.

Insulation Resistance. — The Société Française d'Encouragement pour l'Industrie Nationale offers a prize of 2,000f. (£80) for the construction of an apparatus or the discovery of an industrial method allowing of the rapid measurement of the insulation resistance of different parts of an installation in operation. The prize will be awarded in 1895. Any further particulars may be obtained of the secretary of the society, 44, Rue de Rennes, Paris.

The New Portable Lamp.—We referred last week to the new portable lamp devised by Mr. Max Sussman, and described by Mr. Doubleday at a meeting of the North Staffordshire Mining Institute, at Stoke-on-Trent. In reply to questions, Mr. Doubleday said that none of the lamps had been brought into use in mines. A great many had been and were being tested, and the reports, some of which he read, were favourable to the lamp. The lamp would not be of service as a gas-detector.

The Phonograph.—Automatic machines in connection with the Edison phonograph are said to be fixed at the railway stations in the United States. Thus by putting a penny in the slot and applying the ear pieces of the instrument to the ears, travellers, while waiting for their trains, may enjoy the strains of some popular singer at the opera or concert hall, listen to some passage of a speech in the voice of a prominent orator, or hear a few verses of poetry as recited by some prominent person.

Govan Tramways.—A Board of Trade enquiry has been held in connection with the application of the Town Commissioners for sanction to borrow £60,000 to liquidate the price of the tramways, which were recently taken over by the burgh. Mr. Duncan, of the Glasgow Tramway Company, in reply to questions, said that there was no immediate prospect of the system being worked by mechanical power, and that when it could be proved that electricity was cheaper, they would certainly adopt it, but not until then.

Elmore Copper.—The title of the company which M. P. E. Secrétan is forming in Paris for the acquisition of the Dives works and other assets of Elmore's French Patent Copper Depositing Company, and which had already been acquired by the former from the receiver and manager of the latter, almost takes away one's breath. It is the "Société Française d'Electro-Metallurgie pour la Fabrication du Cuivre et autres Metaux par les procédés Elmore et Secrétan." The objects of the company will be readily understood, but what is implied by M. Secrétan's process?

New Catalogues.—A copy of their illustrated catalogue of electrical fittings and fixtures has been forwarded to us by Messrs. Paterson and Cooper. We notice various kinds of artistic electroliers, billiard fittings, brackets, drop pendants, ceiling fittings, table standards, etc. The same firm send us a copy of their catalogue of switches and switchboards, cables, fuses, casings, etc.; a list of the Phœnix five-ampere arc lamp, which has been designed to meet the demand for a reliable small current lamp; a list of measuring instruments for direct currents; and one referring to the Phœnix direct-current dynamos.

Working Lock Gates by Electricity.—A system devised by Mr. Munro for opening and closing the lock gates of canals by electric power has been tested on the Beauharnois Canal. The experiment was entirely successful, and demonstrated the advantages of electric motors for this purpose. The gates were easily closed or opened by the motors in about one minute, an operation which takes four men three or four times as long to accomplish by hand. As a result of this trial, electric power is to be adopted for the lock gates of the nearly completed Soulanges Canal on the St. Lawrence River, some 30 miles above Montreal.

Cheap Telephony for the City.—The Commissioners of Sewers will no doubt be pleased with the suggestion made by Mr. H. S. Foster, M.P., who asked the former on Tuesday to pass a resolution in favour of his seeking for a license from the Postmaster-General to establish a first-class double-wire telephone service in the City at a maximum charge of £8 per annum. The matter has been referred to the Streets Committee. The same committee had referred to them a circular letter from Mr. R. Starke, convener of the Telephone Committee of the Glasgow Corporation, in the memorandum regarding the contract being negotiated between the Post Office and the National Telephone Company, relating to the telephone system.

Incandescent Lamps.—As will be seen from our advertisement columns, there is a great preparation going on in the matter of making incandescent lamps in view of the lapse of patents next November. The Brush Company are pushing their plans with energy, and will manufacture lamps at their own works under the most improved and modern processes. Having other works, the Brush Company did not require the lamp factory at Hammersmith, and we understand this factory is now in the hands of the General Electric Company, which company is pushing forward the plant to enable it to get an output of over a million lamps per annum. The management of this factory will be in the hands of Mr. C. J. Robertson, who has had considerable experience both in England and on the Continent.

Telegraphic Communication. — The Associated Chambers of Commerce adopted on Wednesday the following resolution submitted by the Wakefield Chamber: "That in the opinion of this association it is unfair to the public that the telegraphic department of the Post Office should for financial purposes be treated as a separate establishment, thereby causing unwarrantable delay in carrying out urgent and much-needed reforms; that inasmuch as the postal establishment and its various departments are in their entirety a financial success, the time has arrived when the address of not exceeding six words should be allowed free of charge in all telegraphs, and that telegraphic communication should be extended to rural districts where practicable, and that a deputation wait upon the Postmaster-General to urge upon him the desirability of adopting this suggestion."

How to Show Lines of Electric Force. — The following experiment for making visible lines of electric force is described by Herr Bruno Kolbe: "Into a flat cylindrical vessel pour purified anhydrous oil of turpentine to a depth of about 2cm., and add some sulphate of quinine. To the rim of the vessel attach two wire springs, adjusted so that the two small metallic balls at their ends dip into the turpentine. Stir the quinine with a glass rod so as

distribute it evenly, and place the vessel on a black cardboard. Join the two wires to the terminals of an influence machine, and turn very slowly. At once the white crystals group themselves so as to form beautiful curves, representing the 'lines of electric force.' The form of these curves recalls that of the brush discharge of the influence machine. Prof. Weiler, of Esslingen, gives the following experiment: Prepare a milky mixture by stirring up finely divided quinine in oil of turpentine. On sending a series of discharges through it, a clearance is produced at the positive pole, and the particles cluster round the negative pole, arranging themselves in streamers directed along the lines of force."

Electricity for Heating Purposes.—The London correspondent of a provincial paper states that it is often said of gas companies that their profits are safe, because, although electricity may be the light of the future, gas will always be a source of revenue for the production of heat and power, but he remarks electric heating is being rapidly developed. Some of the London supplying companies are ordering electric cooking stoves to be lent out to consumers, as gas stoves are by the gas companies, and what is of greater importance, continues the correspondent, is that the electrical compenies are prepared to supply a separate meter and charge half rates for cooking, which they can afford to do, inasmuch as the consumption takes place during the day when the dynamos must generate electricity, and when there is little demand for it for lighting purposes. Besides these ovens there are breakfast cookers, in which eggs and bacon may be cooked on the breakfast table; electric plate-warmers, which are being ordered for London clubs, for they can be kept in the dining-room without any offensive smell as in the case of gas; electric foot-warmers, hot-plates, stewpans, saucepans, kettles, flat-irons, ornamental screens which act as radiators of heat and warm a room, electric curling-iron heaters for ladies, and electric shaving-pots for gentlemen.

Lightning Express Railway Service.—In a letter to the *Times* of yesterday, Mr. F. B. Behr, whose express railway service was referred to in a previous issue, states, in regard to the ventilation of the carriages: "The carriage is lighted by sheets of plate glass, which are fixtures, and is divided, as shown in my pamphlet, into two halves placed on either side of the central rail, leaving a sort of tunnel between these two halves. The tunnel is hermetically closed at the end facing the direction in which the carriage travels, but it is open at the back. It is, therefore, always filled with a column of air which is practically stationary. This air communicates with the bottom of the carriages and escapes at the top by an aperture inclined in the direction opposite to that in which the carriage travels, so that the foul air can freely escape. Thus the carriage will be effectually ventilated without the necessity of windows being opened, and at the same time the column of air in the carriage and tunnel is entirely uninfluenced by the rapid travelling of the carriage, though constantly replenished without any perceptible movement. This leads me to point out that the necessity for placing passengers lengthways and parallel with the rail in any carriage travelling at such a rapid speed, and the necessity for providing a tunnel in the centre of the carriage for purposes of ventilation, as above described, would always necessitate the adoption of a form similar to that of a single-rail Lartigue carriage, even on the ordinary system of railways, and this seems to me an additional proof of the advantage of building such lines on the single-rail system, as I propose."

The Manchester Station.—The five-wire system was brought into operation on Monday, when some 10,000 8-c.p. lamps in the centre of the city were energised. That occasion was not the first on which current had been supplied from the new station in Dickenson-street, because since the end of July there has been, as mentioned in our issue of the 8th inst., a night service between the hours of 5 p.m. and 12 p.m. to certain consumers. The change from the simple parallel system to the five-wire system took place on Saturday night. After the transformation a number of large halls and public buildings were switched on, and on Monday the leading tradesmen whose premises had been connected with the electric mains enjoyed the full benefits of electrical illumination. The Manchester Corporation now has several hundred lamps in the Town Hall, and a large number has been fitted in the Council-chamber, the large hall, etc., which was inspected by the Lord Mayor and members of the Council this week. The total cost of the station, its site, and the appliances will amount to £150,000. One hundred thousand pounds was the original sum, and £70,000 has already been expended, but it is the intention of the City Council to apply for power to spend another £80,000 in extensions which are deemed necessary as the demand for the supply increases. The main building in which are fixed the engines and dynamos is an extensive hall divided into two bays. At present there are two large vertical compound engines of 400 h.p. fixed, and two more similar ones in course of erection. Besides, there will be six other engines of 100 h.p., with the corresponding dynamos. The engines are at present supplied from six boilers of the Lancashire type, with mechanical stokers and economisers.

Electric Lighting in Sheffield.—Some important extensions are now in progress in this town, where the electric light was first introduced about 12 years ago, and very soon the plant being laid down will be capable of supplying 150,000 lamps. The central station is in process of construction in Commercial-street, and transformer stations have been erected in various parts of the town. There will be eight sub-stations, and current will be transmitted to them at a pressure of 2,000 volts. The high-tension system has been adopted on account of the large area to be dealt with—an area which includes every part of the town. As soon as the underground work in connection with the compulsory area is complete, the company will proceed to extend the system to the Broomhill and Ranmoor districts, where a large demand for the current is anticipated. At present the work connected with the reconstruction of the central station is being vigorously proceeded with. Five Babcock and Wilcox boilers have been already put down, and two additional engines and alternators, manufactured by the Brush Company, are being erected. At the central station there is a number of Mordey-Victoria alternators working at a pressure of 2,000 volts. These are rope driven from high speed vertical engines. Effective arrangements have been made for dealing with cases of emergency. Duplicate engines are provided, the company having decided to have a certain percentage of spare plant ready for use when needed. The supply of current is made at present from overhead wires, but the conductors which will supply the town under the new scheme will pass underground. The mains have been laid on the Callendar's bitumen system. The applications for current are numerous, and new and old buildings are being wired in anticipation of the supply of current.

Electric Motive Power.—We have from time to time drawn attention to the increasing employment of electric motors for operating machinery—one of the most complete installations of such being that in the works of the Electric Construction Company at Wolverhampton. Whilst, however, the energy utilised in the

latter instance reaches at the very utmost one or two hundred horse-power, we shall at an early date be able to give full details of plant and machinery in an important manufacturing centre driven entirely by electric motive power, each individual machine or appliance being worked by a separate motor, where the total energy employed will reach a maximum of some 11,000 h.p. The material for this installation is now being shipped from this country, and on its erection the results obtained from daily working will doubtless be looked for with a considerable amount of interest, since waterwheels are to be employed for driving the dynamo generators, and the power station therefore is no insignificant rival to that now being erected at Niagara Falls. The mills wherein the electric motors are to be placed chiefly will engage in jute manufacture: and no shafting of any kind will be used in them. The following details have already been published in the *Mexican Trader* concerning the enterprise: "Mr. Thomas F. Kinnel, the holder of a concession for the establishment of jute factories at Orizaba and elsewhere, has already secured the capital necessary for the erection of the first factory, which will be situated at Barrio Neuvo, Orizaba. The shares, amounting in the aggregate to £100,000, have been placed in London. The foundations of the factory have been dug, and those for the house are being prepared. Work on the canal and tunnel is progressing, and both will shortly be finished. The waterfall is a very fine one, its force equalling 11,000 h.p., with a fall of 115ft. The factory is situated 1½ miles away from, and some 600ft. above the level of, the wheelhouse. Pelton wheels will be exclusively used to drive the machinery through the intervention of electric generators and separate motors. The head-race will be 321ft. in length, the water being conveyed in pipes to the wheelhouse. Four generator dynamos will be used, and every machine in the factory will have a motor of its own, ranging from 1 h.p. to 20 h.p. The whole of the electric plant has been ordered in England, and has been made specially for the work. The buildings are to consist largely of corrugated iron upon iron framing, since the fact that no belting or shafting will be used enables solid masonry to be dispensed with. The contractors for the work are: spinning machinery, Fairbairn, Naylor, Macpherson, and Co., Leeds; weaving machinery, Robertson and Orchar; finishing machinery, Thomson, Son, and Co. The electrical engineer is Mr. A. H. Wood, A.I.E.E., London. The head office is in London, and Mr. James K. Prain is the Dundee representative."

Experience of Electric Traction.—One of the questions discussed at the recent tramway congress held at Budapest, and to which reference was made in previous issues, was very important. It was as follows: (*a*) Have you investigated or had experience in electric haulage, and with what results? (*b*) Under what conditions does it appear to you that electric traction deserves the preference over that of animal or mechanical hitherto used? Some of the remarks made in reply to this will prove of more than usual interest. Mr. Noonenberg mentioned, as is well known, that the working expenses of the Julien accumulator cars experimented with in Brussels for three years, were higher than those incidental to horse cars. Storage-battery cars, as shown by the Frankfort tramway, worked so faultlessly that they would not be rejected by any town; but the financial results were still questionable. The speaker said that the circumstances which had until recently operated adversely to the development of electric tramways in Europe were of various kinds. It was in the first instance thought that the authorities *would not permit* the erection of standards in the streets, and that therefore the companies would be compelled to adopt an underground conductor or the accumulator system. It could, of course, not be doubted that the method of working the overhead system was the most satisfactory. Another difficulty in the way of the adoption of electric power was met with in the case of the tramway companies, who did not wish to be burdened with the considerable expenditure that would be necessary in converting their systems. There was, continued Mr. Nonnenberg, no basis of working expenses in the case of the European electric lines, and upon which the tramway companies could rely as an important factor, and each line had to stand on its own merits in calculating the working expenses in any town. On the conclusion of these remarks, Mr. Hippe, of Munich, who is connected with a steam and horse tramway company, observed that a transformation from one method to an electric system could only be effected provided a satisfactory guarantee was given as to financial success. The question arose, what were the costs of the different powers? According to the reports of the "electricity company," whatever that may mean, the haulage expenses per car mile with horses cost 3d., and with electricity 1½d. per car mile. The difference between the two amounts only rendered possible a conversion from one system to another commercially successful in the most rare cases, and in the greater number of instances the increase in the capital expenditure would certainly diminish the interest on the original capital. For the present Mr. Hippe believed that it was too early to change from a horse system to electric traction, although in the long run electricity would dominate as the motive power on tramways. When that time arrived no one would hesitate about the conversion. Mr. Kruger, of Hanover, referred to the working of a tramway in Hanover, where during a half-year's operations a loss of £400 had occurred. That line was then transformed into an electric tramway, and since then the condition of affairs had changed, the rapidity of the service having quadrupled the receipts. One condition for the prosperity of electric lines was the granting of permission to run the cars at tolerably high speeds. The conversion was of course in a certain measure a leap in the dark, and therefore special care must be taken on a change from one to the other, so that the local authorities not only did not increase the burdens on the enterprise, but, on the contrary, extended the period of the concession and granted certain advantages to the line, otherwise a return on the high costs of transformation would be impossible. Mr. Röhl, of Hamburg, laid stress upon local circumstances, and opined that it would be useless to change a system when the concession was only for 15 years. With regard to Hamburg, an electrical firm had guaranteed that the working costs of the line should be 25 per cent. cheaper than with the existing system, and the speaker said that a conversion was only to be recommended when a firm would undertake to guarantee their estimates. Director von Jellinek expressed the opinion that the figures available as to financial results were mostly only approximate, and from them no definite decision could be taken. Mr. Hamspohn, of the Union Elektricitäts Gesellschaft, said that in America the local authorities furthered electric traction, since it not only facilitated transit, but also had a sanitary effect. After further discussion a resolution was passed stating that the available data with regard to the working expenses of electric tramways were not yet sufficient to allow of a judgment being formed from a financial point of view, but that electric traction was desirable in the public interest.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

DISTRIBUTION OF ELECTRIC POWER.

(Continued from page 247.)

Fig. 29 shows a number of dynamos working into a three wire system, and also how secondary or storage cells are used in conjunction with the dynamos. The method of connecting the dynamos and cells is that usually adopted in central station practice for three-wire systems. As the load increases, another dynamo is switched into parallel, as on the two-wire system. There are three machines shown in parallel in Fig. 29, all working at a pressure of 220 volts. The cells serve two purposes—first, they steady the supply, discharging a current when the load makes heavy demands, thus easing the sudden strain on the dynamos; and absorbing current from the dynamos when the load suddenly falls, thus replenishing the electric energy in the cells, so they may be looked upon somewhat as a "reservoir." Two batteries of cells are used, *b* and *b*¹. These are joined in series across the positive and negative mains, A and B, the third wire,

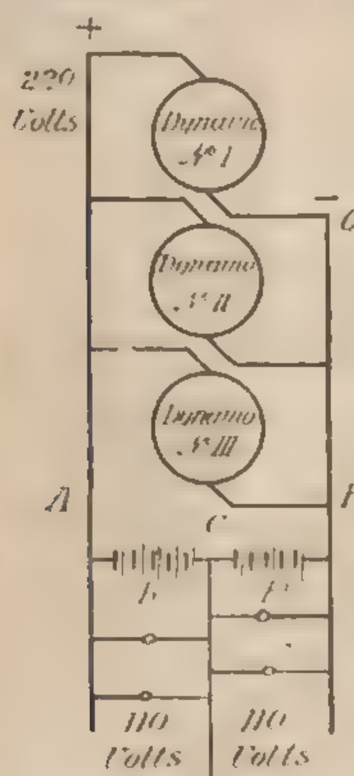

Fig. 29.

C, being run from the junction of *b* and *b*¹; so when the load on the + side is greater than the load on the – side, the battery *b* assists the dynamos. On the other hand, when the load on the – side is greater than that on the + side, then battery *b*¹ assists the dynamos. So far, the third wire is not connected up to the dynamos in any way, and in the case where feeders are used, as in Fig. 28, the third wire is laid down from the feeding centres, thus saving a considerable weight of copper by not taking it back to the generating [illegible]

The original use of the third wire, as invented by Dr. John Hopkinson in 1882, was obtained by coupling together two similar dynamos in series, the + and – cables being connected to the outer + and – terminals of the set, while the third or middle wire was connected to the junction of the inner + and – terminals. The advantage of thus taking the third wire back to the dynamos is that it enables the surplus current to return to the dynamos when the load is greater on one side of the system than on the other side. It need hardly be said that in connecting up lamps on a three wire system it is necessary, as far as actual practice will permit, to arrange the lamp circuits so that the whole of the supply or load is as nearly equally divided as possible—that is, to have as much current taken off the + and third wire as off the – and third wire. When the load on the + side is greater, say, than that on the – side, the difference between the two currents is called the "differential current," and this current will flow along the third wire back to the dynamo on the + side, because that dynamo is working at a greater load than the other. If the – load were greater than the + load the differential current would flow back along the third wire to the dynamo on the – side, and when the loads on both sides are exactly equal then there is a balance and no current flows along the third wire, because the + and – sides are then just as if there were no third wire and they were in simple series. From this the third wire is often called the "balancing wire."

The next development of the parallel systems is found in the five-wire system, and as the three-wire permitted double the pressure that was used in the simple parallel, and hence an extension of area, so the five-wire system permits double the pressure that is used in the three-wire system, and hence a still further extension of area. In this system the dynamos work at, say, 400 volts, three wires being placed between the two outer wires, thus

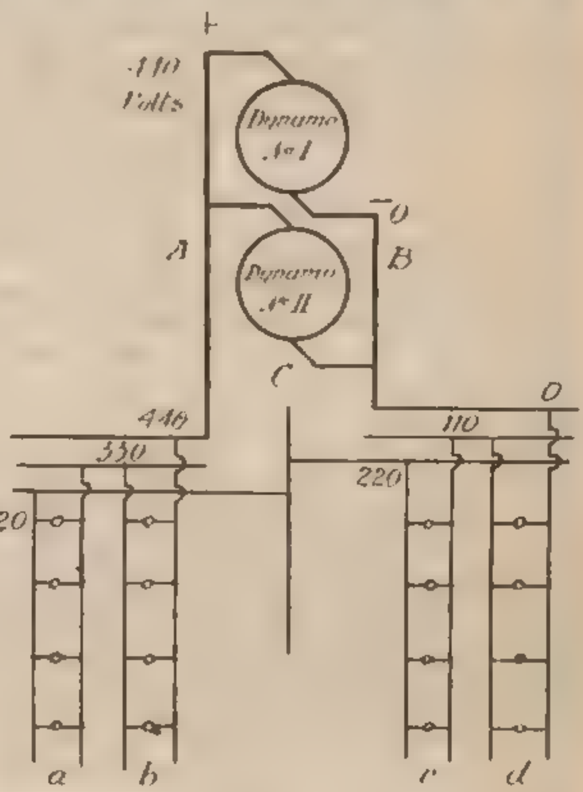

Fig. 30.

making five wires altogether. Lamp circuits requiring 100 volts or so can thus be taken off any two neighbouring wires out of the five; if 200 volts is required, the circuit is taken off any two alternate neighbouring wires; if 300 volts be required, it is taken off, say, the outer + main and the fourth wire and so on. There are thus four circuits of 100 volts in the five wires taken respectively off the + main and the second, the second and the third, the third and the fourth, and the fourth and the – main. Every circuit must have some lamps connected on, and these should as far as possible be distributed equally between the four circuits so as to obtain an equalised load, so in reality these four circuits are all in series, and so make up the 400 odd volts that exist between the two outer cables

Parallel systems are mostly designed for 110 volts pressure at the distributing centres, because 105-volt lamps are mostly used, and the other five volts is a margin for fall of pressure This explains why in Fig. 29 the dynamos are of 220 volts, and the two circuits of 110 volts each; hence in the five-wire system the dynamos are worked usually at 440 volts, giving four circuits of 110 volt
In Fig. 30 the five wires are not all kept
out the supply district, but the diagr

sent the method of supplying two districts that are close together, and both a little distance away from the central station. Two dynamos of 440 volts pressure are shown in parallel—A is the positive cable, and B is the negative; and on account of the pressure being much higher than a simple parallel system, the current flowing through them is much less, and consequently the size and weight of the cables are considerably less, which is a matter of paramount importance when distance has to be considered. When they reach the two districts to be supplied, a third wire, C, is introduced, the + cable and the third wire, C, supplying one district, whilst the negative cable and the third wire, C, supply the other district. We have now a pressure of 220 volts in each district, and again a third wire is added, one to each district, thus making a total of five wires in all, each being at different pressure. In the left-hand district two lamp circuits can now be taken, each of 110 volts. Circuit *b* being taken from the middle wire and A, A is at a pressure of 440 volts, the middle wire will have a pressure of 330 volts, and the difference is 110 volts. Similarly, circuit *a* takes the difference between the middle wire and C, that 330 – 220 = 110 volts as before.

Passing along to the right-hand district, we can in a similar way take off two more circuits, *c* and *d*, each having 110 volts, the last circuit, *d*, taking the difference between 110 and 0 = 110, so that the circuits and their lamps are all in series between A and B, and thus have a working pressure of 440 volts. Great flexibility of distribution can thus be obtained from the use of a five-wire system; it is certainly complicated, particularly when the five wires are carried up to the lamp circuits, and on that account, together with the extra expense in dealing with such complications, is at a disadvantage as compared with simple parallel wires of a high-pressure alternating current.

When feeders are used in the five-wire system they are connected to the two other wires, there being three intermediate wires, so that in Fig. 28, if the middle wire were replaced by three wires, and the pressure of the machines changed from 200 to 400 volts, that would give an illustration of this method of supply.

The loss or waste of electric energy along a pair of mains is a very different thing from the mere loss or fall of pressure, and careful distinction must be made between the two, because the latter depends simply on the current and the resistance of the mains, denoted by C R, while the former depends on the square of the current and the resistance, denoted by C^2 R. We will now investigate what results are obtained when a pair of mains, or feeders, undergo various conditions of working whilst the electric power received by them remains the same, it being assumed that none of the electric power is used along the mains, but the whole of what is transmitted is utilised at the far end of the mains, so that the cables under consideration may be looked upon really as "feeders."

The following will be assumed as the initial or normal condition of things: The feeders have a sectional area of one square inch each, a distance of 200 yards (200 yards positive and 200 yards negative), and a current of 400 amperes flows through at an initial pressure of 100 volts; hence the current density is 400 amperes per square inch, and the electrical power delivered by the dynamo into its end of the feeder is $100 \times 400 = 40{,}000$ watts, or 40 kilowatts. The resistance of such a pair for the above distance of 200 yards may be put down at ·01 of an ohm—that is, one-hundredth of an ohm, being at the rate of ·044 ohm per statute mile when taken at the temperature of 60deg. F., or 15·5deg. C. The increase of resistance due to the current may be neglected, because it is only very small with a low current density of 400. The total weight of copper in both feeders for this distance is 2·08 tons, or 4,660lb. To force 400 amperes through ·01 of an ohm resistance requires $\cdot 01 \times 400 = 4$ volts, so that the pressure at the farther end of the feeders will be 96 volts, two volts being lost in the positive feeder and two in the negative, hence the total fall of pressure is 4 per cent. We can now calculate the loss of energy in the feeders by multiplying the fall of pressure by the current. This is the same thing as multiplying the line resistance by the square of the current, because $C^2 r = C e$, where $e = C r$ = fall of volts. Applying this to the above case, we have 4×400, or $(400)^2 \times \cdot 01 = 1{,}600$ watts. The total energy delivered to the feeders is 40,000 watts, the quantity received at the end of the line is 38,400 watts, so that the loss of energy = 4 per cent. Doubling the pressure and using the same current density, the same power can be transmitted double the distance for the same percentage of fall of pressure or loss of energy; so with 200 volts pressure, the feeders need only have a sectional are of ·5 square inch each, and the current of 200 amperes can thus be driven 400 yards.

It is evidently very clear that when the percentage of fall of pressure or loss of energy must be confined to certain low limits, it is absolutely necessary to employ small currents of high pressure in order to transmit or distribute electric power over long distances or scattered districts.

To show at a glance how the loss varies under different conditions, Tabulation 29 is prepared, the electric power delivered in every case remaining constant—viz., 40 kilowatts. The three most important variables being (1) pressure, (2) distance, (3) current density, when these are known the rest can be found.

TABULATION 29.

Pressure in volts.	Distance in yards.	Current density per square inch.	Area of cable in square inch.	Weight of copper in tons.	Total pressure lost.	Percentage of loss.	
						Pressure.	Energy.
100	200	400	1·00	2·08	4	4	4
200	200	200	1·00	2·08	2	1	1
200	400	200	1·00	4·16	4	2	2
200	200	400	·50	1·04	4	2	2
200	400	400	·50	2·08	8	4	4
400	200	400	·25	0·52	4	1	1
400	400	400	·25	1·04	8	2	2
400	800	400	·25	2·08	16	4	4
800	800	400	·125	1·04	16	2	2
800	1,600	400	·125	2·08	32	4	4
1,600	1,600	400	·0625	1·04	32	2	2
1,600	3,200	400	·0625	2·08	64	4	4

Comparing together the first and the last, it is seen how enormously the distance can be increased by using high-pressure currents, the loss being the same, the weight of copper being the same.

From these figures several useful rules can be obtained:

(1) With current density and distance constant, percentage of loss is ∝ inversely to pressure.

(2) With current density and percentage of loss constant, distance is ∝ to pressure.

(3) With current density and pressure constant, percentage of loss ∝ distance.

(4) With distance and percentage of loss constant, current density ∝ pressure.

(5) With distance and pressure constant, percentage of loss ∝ current density.

(6) With pressure and percentage of loss constant, distance is ∝ inversely to current density.

(To be continued.)

ON STANDARDS OF LOW ELECTRICAL RESISTANCE.*

BY PROF. VIRIAMU JONES.

The preparation of standards of low electrical resistance of from ·001 to ·0001 ohm seems to be a matter of some importance at the present time. These standards are already in request among engineers, and it becomes of interest to consider how they may be best measured to a percentage accuracy comparable with that with which the standard ohm is known.

Such standards of low resistance may be derived by potentiometer methods from the standard ohm by a series of downward steps. But this is, from one point of view, roundabout. The method of measuring the ohm that seems in all its details most accurate is that of Lorenz. In this method the ohm itself is derived from the measurement

* Paper read before the British Association.

of a small resistance. It is simply going up and down again to prepare from the ohm so derived the required small resistance standards, and it is more direct and more accurate to measure the latter directly in absolute measure.

In Lorenz's method a metallic disc, Fig. 1, is made to rotate in the mean plane of a co axial standard coil. Wires touching the centre and circumference of the disc are led to the ends of the resistance to be measured, and the same current is passed through this resistance and the standard coil. The connections being rightly made, we may, by varying either the rate of rotation of the disc or the resistance measured, so arrange matters as to have no change of current in the circuit of the disc and wires joining it to the ends of the resistance, when the direction of the current through the resistance and the standard coil is changed. When this arrangement is effected, there is a balance between the E.M.F. due to the motion of the disc in the magnetic field of the current in the standard coil and the difference of potential at the ends of the resistance, due to the current traversing it. If this adjustment be made, we will say that the apparatus is in an equilibrium position.

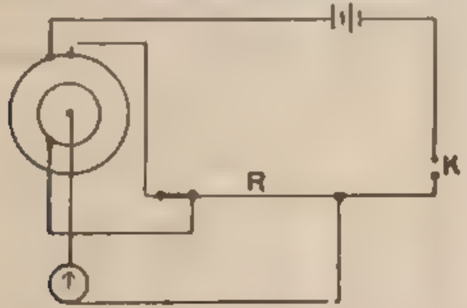

FIG. 1.—Lorenz Arrangement.

If M = coefficient of mutual induction of the standard coil and the circumference of the disc;
n = the rate of rotation of the disc (number of revolutions per second);
R = the resistance;
γ = the current through the standard coil and the resistance;

then in an equilibrium position

$$M n \gamma = R \gamma, \text{ or, } R = M n.^*$$

I do not think that electricians have as yet realised the accuracy and ease with which absolute measurements of resistance may be made by this method.

First let us consider accuracy. The absolute measurements involve measuring, first, the coefficient of mutual induction of a standard coil and the circumference of the rotating disc, and, secondly, the rate of motion of the disc. Now it lies well within the resources of modern mechanical engineering to make a standard coil and disc of dimensions known to an accuracy considerably greater than 1 in 10,000, the coil being constructed of a single layer of wire wound in a screw thread cut in a cylinder of large diameter, and the measurement of the rate of motion to equal accuracy is a simple matter. There is difficulty in maintaining a rate of rotation constant to this figure for four or five minutes, but with the closest attention to the lubrication of all the bearings this also might be accomplished. Such constancy is well worth striving for, as the ease with which measurements of resistance can be made by the method largely depends upon it, and this brings me to the second point I mentioned—viz., the facility with which accurate measurements may be made with a well-constructed Lorenz apparatus.

I do not propose on this occasion to enter into the details of the method I have adopted in making the measurements, the results of which I have presently to bring before the section, but it will be perhaps of interest if I say a word or two about the time measurement.

In measuring a resistance we have to find the rate of rotation corresponding to an equilibrium position. It is easiest in practice to determine this by interpolation from two determined rates of rotation (near together, and respectively slower and faster than the required rate), and the galvanometer deflections corresponding to them, so that each determination of resistance involves no determination of galvanometer deflection and of the rates of rotation corresponding to them.

* *Phil. Trans.*, 1891, Ap. 2.

In order that the galvanometer deflection may be obtained with sufficient accuracy from a limited number of reversals (in my observations the number has been almost uniformly 33, taking about four minutes in each case), the brush at the circumference of the disc needs to be perforated and to be supplied with a constant stream of mercury. Such a brush in its best condition almost entirely eliminates the continual jerking of the galvanometer needle, consequent in thermo electric changes at the point of contact of brush and disc. A multiplication of such brushes at three or four points of the circumference would do this more completely.

During the four or five minutes' run, the rate of rotation is referred by a stroboscopic method to a suitable tuning-fork provided with riders maintained in vibration electrically. The observer at the fork can shunt more or less current through the electromotor driving the disc, and in this way maintains the rate of rotation as constant as he can. But though the electrically-maintained fork is useful for purposes of control, it cannot be relied on to give us the rate of rotation. Its vibration period is not, within my experience, constant to the degree of accuracy required. If stopped and set going again it may start with a period difference by several ten-thousandths. No previous determination of the period of the fork could, therefore, be relied on to give us the rate of rotation, though once started the fork goes sufficiently uniformly to give us a means of control.

Accordingly it is necessary to measure the rate of rotation during each run while the galvanometer observations are being made. The rotating disc is, therefore, by means of an eccentric attached to its axle, made to record its revolution on the lapse of a Bains electro chemical telegraph instrument side by side with the record of the standard clock. We have then a time record exactly corresponding to the period of observations of the galvanometer deflecting. During the run, then, we have simultaneously the observer at the galvanometer calling out the galvanometer deflections, and the observer at the tuning-fork controlling the speed, while the Bains instrument records it.

I have made in this way a number of measurements during the months of July and August of a standard resistance approximately ·0005 ohm, prepared last year by my assistant, Mr. Harrison, and a student in my laboratory, Mr. Parker, with the following results:

July 17, morning	·00050016
,, ,, afternoon	·00050016
,, 19, morning	·00050015
Aug. 2, afternoon	·00050020
,, 3, morning	·00050021
,, 4, morning	·00050016
,, 4, afternoon	·00050013
,, 5, morning	·00050019
,, 9, morning	·00050021
,, 9, afternoon	·00050018
	·175
Mean	·00050017

that maximum divergence from the mean is ·00000004 in about 1 part in 12,000.

Mr. Crompton has been recently issuing standards of low resistance made of manganin sheet, and he was kind enough, at my suggestion, to send me one for measurement towards the end of July. It was prepared in his laboratory as a derivation from the International ohm by means of his potentimeter. Its value so given was ·00050175 at 23deg. C. Its temperature coefficient appears from Mr. Crompton's measurements to be so small that we need hardly consider it for our present purpose. My measurement of this standard was as follows:

July 29, morning	·00050219
Aug. 1, morning	·00050225
,, 1, afternoon	·00050219
,, 2, morning	·00050226
Mean	4189
	·0005[illegible]
Mr. Crompton's value	[illegible]
Difference	

is about 1 part in 1,000

Mr. Crompton's resistance is a rectangular sheet of manganin, and the potential terminals are two screws inserted at a suitable distance apart in the medium line.

Current Terminals.

The screws are not soldered. I thought it would be of interest to measure them; then screw them up again and remeasure the resistance. The results were:

Aug. 10, morning	·00050328
,, afternoon	·00050322
	·00050327
Mean	·00050326

a variation of about 1 part in 500.

I measured them again, and after screwing them once more remeasured with the following results:

Aug. 11, morning	·00050398
,, 12 ,,	·00050403
Mean	·00050401

which, compared with the first value ·0005022, gives a variation of, roughly, 1 part in 300.

The conclusion is that if Mr. Crompton desires an accuracy of $\frac{1}{10}$ per cent., which he is apparently able to obtain by his potentiometer method, he must not leave his potential terminals of his resistance loose. They must be soldered into his plate.

In making these measurements my direct object has been to obtain an accurate and ready method of measuring these low resistances. But I think something more than this comes out of them. It would be possible in the light of our present experience to construct a Lorenz apparatus considerably more accurate and easier to use than one in my laboratory at Cardiff. Such an apparatus placed in the national laboratory of which we have heard a good deal at recent meetings of the British Association, might with advantage be kept in constant use, not only for the calibration of low resistances, but also as embodying in concrete form a proper ultimate standard of electrical resistance. We have not in our electrical standard legislation given full credit to the mechanical engineer for what he can do for us, and I think that a coefficient of mutual induction arranged as in the Lorenz method, so as to be easily combined with a time, would afford a more satisfactory ultimate standard of resistance than any wire coil or coils, and one easier to use for purposes of ultimate reference than any mercury columns.

ELECTRIC LIGHT—THERMAL STORAGE—UTILISATION OF TOWN'S REFUSE.*

BY CLAUDE CHAS. KEEP.

The increasing demand for electric light has been the means of bringing the question of the profitable disposal of refuse more prominently before the public during the last two years than at any previous time. Not a week passes without one or more of the technical journals containing articles on the subject of the title chosen for this paper. Reports on electric lighting schemes by the most eminent of our engineers usually refer to it: a few say it is possible, some that it is merely probable, others again that it is impossible, to combine the two. I hope to show that it is not only possible but practicable and economical to light cities and towns, in whole or in part, by burning the refuse accumulations. But without Mr. Halpin's system of thermal storage nothing of any magnitude can be done, as the disposal of the refuse must naturally proceed uniformly, and the demand for the electric light obviously varies during each moment of the 24 hours. Thermal storage may be described as the bank: it receives the continuous but irregular earnings of the destructor, and by its well-regulated system is able to pay on demand all it has received to its regular customers, meeting their varying requirements, only charging a small percentage for the accommodation it has provided.

I purpose first to deal with the refuse question, the disposal of which must be considered primarily from the standpoint of public health, and, secondly, from that of finance; and in order to help us to come to a conclusion it will be as well to say what town's refuse consists of: Dust, ashes, wood, straw, paper, baskets, bricks, bottles, tin cans, old boots and shoes, brushes, oyster shells, old clothes, scraps of oilcloth and carpets, decaying food, dead dogs and cats, cinders, garbage, etc., collected from the markets (sometimes dry, frequently very wet); animals slaughtered when suffering from disease have also to be disposed of.

Means of Disposal.—By depositing in tips—such as disused sand and gravel pits, quarries—and filling-up low-lying ground. *By storing* in a field, with a view to selling a portion during manurial season of the year. *By sorting* and sifting out the breeze cinders and fine ash (this operation is usually performed by women). I think neither of these methods of disposal can be said to comply with the requirements of public health, and in order to show that it is a failure financially, we have only to turn to the reports of the sanitary authorities. One I have in mind received £7,000 annually; it now has to pay double this amount to dispose of it in various "tips."

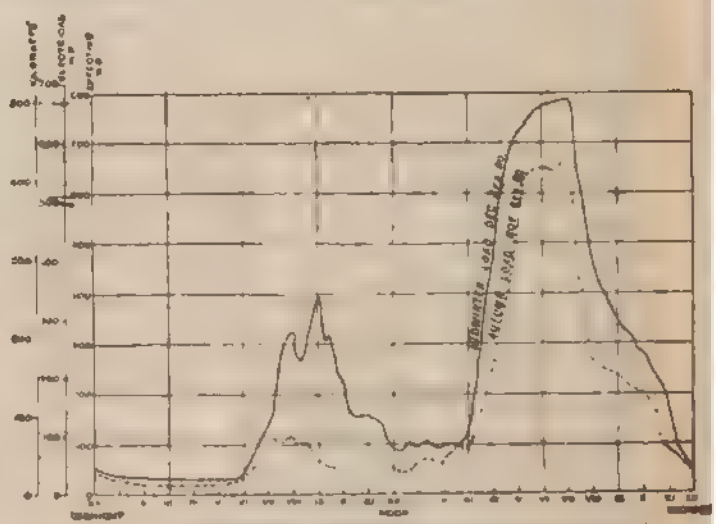
Destruction by fire completely complies with the requirements of public health, and destructors, if properly constructed and managed with ordinary care, can be erected in or quite close to cities and town without causing the least complaint, and can be made a success financially. The late Mr. Alfred Fryer invented the furnace known as "the destructor." He not only designed and patented this furnace, but coined the word "destructor," and registered it as a trade-mark. His furnaces have been erected in between 40 to 50 different towns, and have successfully dealt with all descriptions of refuse, the midden contents—sewage sludge from precipitation tanks mixed with refuse, and with dust-bin contents, which is the easiest of all refuse to burn. I am aware other furnaces have been erected in a few towns, and unfortunately have been called by the same name. The essence of Mr. Fryer's patent is the sloping hearth and grate, and the arrangement for feeding or charging the furnaces at the back, and the clinkering or cleaning of the fires at the front. In this, everyone who attempts to erect furnaces for this purpose, and who have met with any degree of success, have copied Mr. Fryer's idea, only varying in some slight details. Reports have lately appeared in praise of some of these alterations, but older students of the subject will remember, 10 to 14 years ago, most of these arrangements were tried and abandoned—for one reason, they failed in their action owing to the character of the refuse at that time: it was collected at periods varying from once a month to once in 12 months, from deep middens, generally saturated with slops, urine, excreta, etc. The water-carriage system has disposed of this difficulty, but has left with us yet another—viz., the enormous cost for repairs of the furnaces. Those features of the furnaces most discussed at the present time are automatic feeding of the fires and forced draught. Automatic feeding will not be a success so long as refuse consists of the variety of material I have mentioned. It may be stated that one fire will need to be cleaned of the clinker, etc., and recharged in less than 20 minutes, while the next charge will take from one to two hours to burn off. Automatic feeding of the fires may be more or less successful if the refuse is sorted and screened, and only the cinders are burnt, but the cost of this screening operation makes it prohibitive (Sir Spencer Wells says the system is born of a spurious economy at the cost of human life), and the material most difficult to deal with is still left to be disposed of. It is perhaps not too much to say that more complaints are made about automatic stokers working ordinary furnaces than about any other class of machinery in this country, and these, it must be noted, used screened and carefully selected coal. I believe the nearest approach to this object is to be found in Brodie and Boulnois's patent charging apparatus. I shall describe it in the words of the city engineer of Liverpool. The apparatus consists of a wrought-iron truck 5ft. in width by 3ft. in depth, and of such length as will cause it to be of sufficient capacity to hold not less than 12 hours' supply for the two cells which it commands. This truck moves along a pair of rails laid across the top of the destructor, and is capable of being worked by one man. The truck is divided into compartments holding a charge in each,

* Paper read before the British Association.

and provided with a pair of doors at the bottom opening downwards, which are supported by a series of small wheels running on a central rail. A special feeding opening in the reverberatory arch of the cell of the full width of the truck (5ft.), and placed immediately over the drying hearth, is constructed of a firebrick arch fitted into a frame capable of being moved backwards and forwards by means of a lever arrangement. The truck when empty is brought under the tipping platform, and the carts tip their contents directly into it; and when it is required to feed one of the cells, the truck is moved along so that one of the divisions is immediately above the feeding opening, and the wheel holding up the bottom doors rests upon the central rail, which is continued over the movable covering arch. Then the movable arch, actuated by the lever, is rolled back, releasing the doors and discharging the contents into the cell, so that no handling of the refuse is required from tipping to feeding. This arrangement provides portable storage for a large quantity of material, and entirely does away with the necessity for the shovelling and handling.

Forced Draught.—I find this was claimed in the original patent of Mr. Fryer. It has been applied in several places where the chimney has not been of the right design, and it has answered fairly well. At Birmingham, steam-jets have been in use several years, and extended tests have been made both with jets and fan blasts. The manager has come to the conclusion the best results are obtained by the latter. At Bradford, steam-jets blowing into large pipes have been tried, and have lately been abandoned on several of the furnaces, and jets more after the design of those in use at Huddersfield have been substituted; while at Battersea the jets first used at Bradford were tried and failed to give as good results as natural draught. Another point much debated arises over the adoption of Jones's fume cremator. Grossly exaggerated statements have been made as to the cost of working this adjunct to the destructor. Without entering into this question at the present time, and as in the future boilers will almost invariably be placed in destructor flues, objections arising from cost of working fall entirely to the ground, owing to the fact that the heat generated by its use can be satisfactorily employed.

Time will not permit me to go further into the detail of the construction of the furnaces, so I will now proceed to give you an idea as to the calorific value of the refuse. Most extravagant statements have been made about this. I have only to refer you to what I previously said refuse is composed of, and to remind you no two cartloads contain exactly the same proportions. Statements have appeared professing to give the exact composition of London dust. If these statements were the result of a whole year's collection, one might look to them for guidance. It has also been stated in the public press that the calorific value of average refuse is equivalent to 4lb. of water evaporated per hour per 1lb. of combustible matter in the refuse from and at 212deg. F., and it has also been stated elsewhere the same quantity of refuse will evaporate 0·01116lb. of water from and at 212deg. F. The one amount exceeding the other 400 times! This great discrepancy is due to the total absence of any reliable and scientific information obtained by prolonged and accurate experiments. The better result referred to was, I believe, obtained by burning a few tons of refuse under exceptionally favourable conditions totally inapplicable to general use. There appears some reason for believing the lower figure is due to very inaccurate measurements. The collection of refuse is so arranged that the destructor receives the refuse of one particular portion of its district on one particular day of the week. Each portion of a district will probably give a distinctly different quality of refuse to that of its neighbouring portion, consequently the calorific value of the refuse collected on a Tuesday will vary from that collected on Wednesday, but the total heat generated by the destructor during one week will be very nearly equal to that generated in the following or preceding week. Hence, if the dust is collected weekly from dust bins, the week is the time in which the complete cycle of changes in temperature takes place in the destructor fires. The results that can be taken from one week's working are comparable to a single steam-engine indicator diagram. We all know the danger of deducing much from a single indicator diagram. Careful observers are not satisfied unless they take a number of such diagrams and deduce their results from the mean, because, under ordinary working conditions, the load varies throughout the day. Now, under normal conditions the work of the destructor varies from summer to winter, consequently, to obtain really reliable average data, the result of one complete year's working must be acquired. Fortunately, the dust production and the electric light requirements vary in somewhat similar proportions during the summer and winter. The data of trials of the most recent type of destructors have not yet been completed, and, therefore, under the circumstances I may, perhaps, be excused for referring to trials of older destructors which have not been made generally public. At Birmingham the average evaporative power of 1lb. of refuse has been found to be equal to the evaporation of 1·79lb. water per hour. The refuse was burnt in furnaces of different types, and this result is the average of the whole burning during several years. At Warrington a different class of refuse has to be destroyed, where the evaporative power was found to be 1·47lb. water per 1lb. of refuse. I mention these two cases to indicate how great may be the difference in the calorific value of refuse collected in different towns, and it tends to prove that each town must be considered on its own merits.



LOAD CURVES KENSINGTON COURT ELECTRIC STATION

Diagram No. 1.

I should like to draw attention to the preference some engineers at the present time are giving to complicated mechanical arrangements in the furnaces. I cannot emphasise too strongly that the design of furnaces for burning refuse should be of the utmost simplicity and durability. The stoppage of a town destructor on account of repairs or some trifling breakdown in the machinery, even for a few hours, completely disorganises the whole sanitary arrangements of a town, and when in addition to this drawback the power which would have been generated to produce electric light falls short, a whole district might be thrown into confusion. Destructors can and have been erected in such a way that they have never ceased work for seven years, day and night. It may therefore be concluded that such destructor would at all events not require greater stoppage than ordinary boilers in use in central electric lighting stations.

In concluding this portion of my paper, I wish it to be distinctly understood that destructors must work continuously day and night, and as, apart from the quality of the refuse, the heat production of the destructor is nearly uniform, but is not in the most utilisable form for the generation of steam for motive power to provide electricity, hence, owing to the irregular demand for the light, the necessity for the application of Mr. Druitt Halpi[illegible] thermal storage.

It has been attempted in som[illegible] the inconvenience arising fro[illegible]

tricity by using accumulators. Their heavy prime cost, great space occupied, their costly and rapid depreciation, their efficiency of only 80 per cent., form objectionable features that militate heavily against their general adoption. I must ask you to look for a moment at the lighting curve for electric lighting. The same applies to gas—if gasometers did not exist, the gas industry would be impossible, owing to its want of financial success due to the enormous number of retorts that would have to be used to provide for the maximum load, and to the fact that these retorts must be stopped and started exactly as the demand varies, thus causing them to be subjected to excessive wear and tear owing to the sudden heating and cooling, in addition to great fuel losses, and the labour of stoking being performed in a most uneconomical way. Before proceeding to further explain Mr. Druitt Halpin's system, I wish to call your attention to diagram No. 1; this represents the lighting curve for Kensington Court station. It is taken from Mr. Crompton's paper read before the Institution of Civil Engineers, and is an average curve for a mid-winter day. Engineers prefer to provide boiler power sufficient to meet the maximum demand. The extremely short period of this duty necessitates the laying by of the greater portion of the boiler plant for frequently two-thirds or even more of the 24 hours. Not only is this an objectionable practice on financial grounds, but the constant banking-up and relighting of boiler fires involves a heavy thermal loss, the magnitude of which has probably never been accurately estimated, in addition to great loss in efficiently utilising the labour of the stokers; moreover, the quality of the water supply must influence the life of the boiler, which, in an extensive boiler plant, will probably be found to affect dividends to an extent not yet contemplated. The conditions of a good electric lighting central-station plant, therefore, involve the reduction of the boiler power to a minimum, and the omission of the present expensive accumulator system, combined with an ample supply of suitable boiler feed-water. After studying for a considerable period the principles underlying Mr. Druitt Halpin's thermal storage system, of which so much has been said and written during the past year, I have come to the conclusion that these difficulties can be overcome by its adoption. By a fortunate combination of circumstances it is also peculiarly adapted to use with the destructor.

The system of thermal storage contemplates the working of a sufficient number of boilers during the whole 24 hours to produce the mean desired amount of steam and deliver the steam given off into reservoirs of suitable strength and capacity, containing sufficient water to store up part of the heat in the steam when the engines are working at a light load or when stopped to store up all the heat the boilers can produce. The boilers are preferably worked at a higher pressure than the engines, and the difference of pressure between the engines and the boilers is necessarily accompanied by a difference of temperature, and having a large mass of water available at this higher temperature really constitutes the source of the stored energy, thus justifying the application of the title of thermal storage to the system. It is well known that the majority of boilers are fed with more or less impure water, but in the thermal storage system the impurities are deposited in a place where they can do no harm, and the boilers are fed with clean water, thus avoiding incrustation, which entails expensive and imperfect cleaning, thus obviating the loss of fuel due to deposit, and reducing materially the wear and tear of the boilers.

Mr. Halpin's system may be carried out in whole or in part. *The first scheme (called steam storage)* contemplates the heating of such a volume of water during slack times by the excess steam, that this water will be able to provide the necessary excess of steam for the engines during heavy load, and thus to evaporate such portions of this water as the boilers are not able to cope with. It will be found that in this system the whole of the excess steam generated during the light load of 16½ hours can be utilised in heating the water and given back again in sufficient quantity during heavy load to enable the boilers to be worked uniformly throughout. A feature of this scheme is that a uniform continuous feed is contemplated. (It may be called *complete steam thermal storage*.)

The second scheme (called feed storage) is a means of providing the boilers with clean feed-water at the temperature of the steam in the boilers. The whole of the feed-water needed for evaporation during the 24 hours is pumped into storage tanks, and during the light-load period of, say, 16½ hours it is raised to the temperature of evaporation by the excess steam generated during this light-load period. During heavy load the boiler can be supplied with feed-water at the temperature of the steam, but the fires have still to supply the heat necessary to produce evaporation—that is, to add the latent heat to the steam.

The third scheme (called combined feed and steam storage) is simply a combination of the first and second schemes, and differs only in the period of delivery and temperature of boiler feed-water. In this case, the whole of the feed-water is delivered into thermal storage reservoirs and heated during slack load to the required temperature of evaporation. This also is a complete thermal storage system.

As all these schemes must be reduced to figures to enable you to judge of their practicability, I will now take an instance of a district of the city of Edinburgh for which I have been enabled to obtain sufficient data. I am informed that the lighting curve before referred to may be assumed to represent that for this district without great inaccuracy.

Assume that feed storage tanks only be provided sufficient to hold the whole of the water required by the engines during the 7·1 hours' heavy load, and that this volume is heated from 100deg. F. to 347deg. F. = 115lb., the pressure at which the engines are working during slack load. Without wearying you with all calculations (which I have given in detail in the appendix), it may be seen that with hot feed the boiler power can be reduced 22 per cent., and that this reduced boiler power will only have to work 4¾ hours at full power, or the equivalent thereof, out of the 16·9 hours of light load. Owing to the reduction in boiler power, the total prime cost of the plant with feed storage tanks is almost exactly the same as if boilers had been provided to do the whole work, and in addition to this the necessity for extra chimney that would be required by those boilers detached from the destructors entirely disappears. Working expenses of the plant with storage tanks should be considerably less, owing to the more regular duty which is imposed upon the boilers, and to the fact that incrustations will be absent in the boilers. As all the necessary heat is obtained from the refuse burned in the destructors, the whole of the fuel and labour of stoking otherwise required is obviously saved.

Secondly. Assume the plant fitted up with thermal storage tanks and feed storage tanks on the lines of the third scheme. The boilers in this case are supposed to work at 250lb. pressure and capable of meeting the average load during the 24 hours, but experience has shown that the high pressure will not cause any difficulty either in the boilers or in the thermal storage reservoirs. You are no doubt aware that tanks, 8ft. diameter × 30ft. long, working at 250lb. pressure, have been in use for some time for creosoting purposes. It is assumed the engines work, as before, at 115lb. pressure, and from the figures in the appendix it may be seen that the boiler power need only be one-third of that required if no thermal storage reservoirs were provided. Referring again to the figures in the appendix, it will be seen that even with an evaporative power of 1lb. water to 1lb. refuse, and allowing 40lb. water per kilowatt, that ample heat can be generated by the destructors by the burning of 80 tons per diem to supply the whole of the steam for such a central station.

I have shown that at Warrington the average evaporative power of the refuse throughout the year is 1·47lb. of water per pound of refuse. My experience in this matter teaches me that it is unlikely the summer's evaporative power will be less than 1lb. per 1lb. of refuse; the equivalent figure during the winter months will probably approach 2lb. water per 1lb. refuse, and hence you will notice I have based my calculations of the evaporative power on the assumption that summer refuse is supplied to the destructor throughout the year, but that the electric light is produced according to winter requirements. I may observe that at Liverpool the duty produced by the boilers in the winter is four times as great as that obtained in summer.

In concluding this paper, I may be allowed to express the hope that your patience has not been overtaxed. It will readily be admitted that the importance of the subject can scarcely be overestimated. The various opinions held by engineers are doubtless represented amongst my hearers, and though I can hardly hope to have succeeded in convincing all as to the position I have taken up, I do trust that in this direction something has been done. The subject I hope will be favoured with the best consideration and the most incisive criticism of all the sections, as it is only in this way the truth can be arrived at and thoroughly established.

APPENDIX.

The day of 24 hours may be divided into two periods—*i.e.*, period of slack load; period of heavy load. Period of slack load amount to 16·9 hours; period of heavy load amount to 7·1 (3.15 p.m. to about 10.20 p.m.). It is true that from 7.20 a.m. to about 9.40 a.m. the mean load is slightly exceeded, but of course, so far as storage tanks are concerned, they must be provided for the *greatest excess load* only.

Second Scheme (Feed Storage).—Let the storage tanks be sufficient to hold whole of water necessary for engines during 7·1 hours heavy load, and that this volume be heated from 100deg. F. to 347deg. F. during slack load. The boilers and engines work at 115lb. Now the maximum rate at which the power is required is 597·7 kilowatts, or about 800 e.h.p. The mean load on engines = 187·5 kilowatts, and for the given working conditions it may fairly be assumed that not more than 40lb. of water per hour per kilowatt will be consumed. Hence the average water consumption per hour should be 7,500lb. Total water used during 24 hours, 180,000lb.

Note.—Without storage tanks the maximum steam to be supplied by boilers (597·7 × 40lb. per hour = 23,908lb. per hour from 100deg. F. at 347deg. F.

Maximum heat required = 23,908 (1,220 − 100) thermal units per hour = 26,778,000 thermal units.

Now with storage tanks delivering feed at 347deg. F.

Maximum heat required = 23,908 (1,220 − 347) thermal units per hour = 20,873,000 thermal units.

Hence if feed can be supplied at 347deg. F., the boiler powers can be reduced in ratio $\frac{20,873,000}{26,778,000} = 0·7795$ or by 22 per cent.

Next, given storage tanks for heavy load, can 180,000lb. be heated from 100deg. F. to 347deg. F. during 16·9 hours slack load? By hypothesis the total boiler power is capable of furnishing 20,873,000 thermal units per hour.

During light load, 16·9 hours, the boilers have:

(1) To provide latent heat for engine steam.

(2) To raise 180,000lb. water from 100deg. F. to 347deg. F.

Area under curve during the light load = 0·973 square inch, length of base = 2·64in., therefore mean heat = $\frac{0·973}{2·64}$ = 0·3686in.

The scales are 1in. = 6·3995 hours, and 1in. = 247 kilowatts, or 9,880lb. water per hour.

Hence mean boiler duty during 16·9 hours = 0·3686 × 9,880lb. water per hour = 3,642lb. per hour, and total water during light load = 3,642 × 16·9 = 61,550lb.

	Thermal units.
Latent heat of evaporation of 61,550lb. at 347deg. F. = 61,550 × 873 thermal units ...	= 53,730,000
Raising 180,000lb. 247deg. F. = 180,000 × 247deg. F. thermal units	= 44,464,000
Total boiler duty during 16·9 hours' light load in thermal units	98,194,000

The boilers are capable of giving 20,873,000 thermal units per hour; hence, they will have to work $\frac{98,194,000}{20,873,000}$ hours = 4·70 hours at full power (or the equivalent thereof) during the 16·9 hours' light load.

Total Tank Capacity.—Water to be stored = water of evaporation during 7·1 hours' heavy load.

Area enclosed between curve and base line during this 7·1 hours = 1·827in.

$$\text{Mean heat} = \frac{\text{area}}{\text{base}} = \frac{1·827}{1·11} = 1·6459\text{in.}$$

1·6459 = (1·6459 × 9,880) lb. water per hour = 16,262lb. per hour.

Total water = (16,262 × 7·1) lb. = 115,465lb.

Assume net capacity of one tank = 75,000lb., then number of tanks = $\frac{115,465}{75,000}$ = 1·54 tanks.

Allow 12 per cent. for water expansion 0·2 tank.

Total tanks required = 1·54 tanks, say 1·75 tanks.

Relative Cost of Boiler Scheme With and Without Storage.—Without storage, boilers must be capable of evaporating from 100deg. F. at 347deg. F. 23,908lb. per hour, and must be capable of yielding about 800 e.h.p. Assuming cost of water-tube boilers to be £3 per electrical horse-power, then cost of boilers = £2,400.

We have seen that with storage the boilers may be reduced 22 per cent., hence cost is then	£1,872
Allowing £500 for each tank, 500 × 175	875
Total cost	£2,747

For a small scheme such as this, the difference in first cost is not great, and in large schemes difference is in favour of thermal storage system.

Third System (Complete Thermal Storage and Feed Storage). Boilers work at 250lb., and are sufficient for average load only. Whole feed is supplied during light load, and the storage water at 406deg. F. is sufficient to contain heat for latent heat of evaporation for excess steam during heavy load.

Available range of temperature, 59deg. F.

Engines work at 115lb., or 347deg. F.

Boiler duty during light load comprises:

1. Heating of 180,000lb. water from 100deg. F. to 347deg. F. (feed). 2. Heating storage-tank water from 347deg. F., to 406deg. F. 3. Evaporating 44,349lb. water at 347deg. F., being water required during light load for engines.

The excess steam to be evaporated by storage-tank water is shown on diagram enclosed between red curve and mean height line.

This area in all = 0·66 square inch = 41,735lb. water to be evaporated at 347deg. F.

Total heat required = 41,735 × 873 thermal units.

Storage water in tanks = 41,735 × 873lb. = 617,500lb.

(Storage water only falls 59deg. F. in temperature.)

Number of tanks required for steam water storage

$$= \frac{617,500}{75,000} = 8·23.$$

Allowing 12 per cent. for water expansion, about nine tanks are required. For feed-water storage we have seen about 1·75 tanks are required.

About 11 tanks in all are necessary.

Returning to boiler duty during light load—

				Thermal units.
(1)	180,000 × 247	thermal units	=	44,462,000
(2)	617,500 × 59	" "	=	36,438,000
(3)	44,349 × 873	" "	=	38,712,000
				119,612,000

Average boiler duty = 8,981,000 thermal units per hour.

$$\frac{119,612,000}{8,981,000} = 13·32 \text{ hours.}$$

9·395 (heavy load period).

22·715 hours.

During the 24 hours the boilers work at full power for 22·7 hours.

In this scheme the boilers are proportioned to give 187·5 kilowatts, or about 250 e.h.p.

Costs of this Scheme.

Eleven storage tanks at £600 each, to stand 250lb. per square inch, and to contain 75,000lb. water...	£6,600
Boilers to give 250 e.h.p. at £3 per e.h.p. plus 5 per cent. for extra pressure	850
	£7,450

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

WERNER VON SIEMENS.

There are some names that live in history, there are others which abound for a season and are soon forgotten. The name of Siemens is one that will last, because it belongs to those who have made history rather than to those who loom largely before their generation as expounders without orignation. It is not our intention to dwell lengthily upon the personal characteristics, or even the personal work, of this scion of a celebrated family—a full account of these will be found in the personal recollections just published in book form by Messrs. Asher and Co. If we attempt to consider, not the position of one brother but the work the house of Siemens has done in the development of electrical engineering, we must acknowledge that it has ever been in the forefront; that by its brain power, coupled with its excellent mechanical exposition of that brain power, it has done more than any other house or firm to make the world acknowledge the possibilities of electricity. Almost the first paragraph of the book above referred to shows the characteristic moving spirit of the Siemens brothers. Whether physically, mentally, or commercially, troubles loomed ahead, they met them, and energetically repelled them. Werner met with success in driving away a troublesome gander, because he reasoned that his father's experience was right, though his own fears might lead to an opposite conclusion. The young warrior scored a victory which stood him in good stead in after years. When reason and experience said a thing could be done, whenever they pointed to a probability of its being done, no stone was left unturned to succeed. Brother assisted brother, and with the aid of Halske, whose name is inseparably connected with that of Siemens, the success has been great. Telegraphy in the public mind has given place to electric lighting and transmission of power. Familiarity with it has led to a depreciated idea of its effect upon the history of the world, but to those who can recollect the methods of communication before the end of the thirties, and compare the then methods with those now so common, the difference is startling. In every branch of telegraphy the house of Siemens has taken a prominent position; but let us consider for a moment what it has done for electric lighting and transmission of power. We have the names of Pacinotti and Gramme continuously before us, although a closer attention to history would show that Siemens could claim as prominent a position in the development of the dynamo. The recollections contain references to the controversy as to the application of guttapercha for insulating purposes, and a history of telegraphic progress both on land and on the ocean bed. It is, however, to the history of the dynamo that attention is here directed. On page 330 the recollections say: "This was the discovery and first application of the dynamo-electric principle underlying all dynamo-electric machines." The paper embodying the descriptive details of this discovery was, if we recollect aright, read at the Royal Society in conjunction with one of Prof. Wheatstone's, in which a similar discovery was described. These two Royal Society papers are

always quoted as showing how discoveries in the same direction can be made independently by workers far apart. The claim of Werner Siemens to priority is shown and has generally been admitted. How rapid the development has been during the quarter of a century succeeding this discovery is known to us all; and again the house of Siemens has been the foremost of the workers. It is good that such recollections are published. It is good in times when the principles involved and the apparatus employed are common knowledge to now and again consider the step which led to the known from the unknown—a step seemingly small and plain, but one which was long a-coming, yet when taken changed the course of civilisation. To the Siemens brothers belong all honour and credit for this and other discoveries; hence a book of recollections plainly setting forth the working of the mind of one of these eminent men is of value to all engaged in like work. Mankind, in the stress of living, is too apt to run to extremes of praise and blame, but the earnest workers in electrical matters will agree that in this direction the meed of praise to the Siemens family can hardly be made too great.

ELECTRICAL PAPERS READ BEFORE SECTION A OF THE BRITISH ASSOCIATION, 1893.

BY JAMES L. HOWARD, D.SC.

Since the Mechanical Science Section of the British Association (Section G) began to devote one of its sittings to the discussion of papers on subjects connected with electrical engineering, the electrical papers of the Physical Section have become annually less and less technical in character. This tendency has been shown very clearly at the recent meeting, where a large percentage of the electrical papers referred to that portion of the science which the uninitiated commonly, but somewhat vaguely and erroneously, call "Maxwell." But in spite of this several results of interest to electricians were made known, which it will be best to describe in order.

The Committee on Solar Radiation have in past years measured the intensity of the sun's heat by the rise of temperature of a mercury thermometer whose green glass bulb was exposed to it. Such a thermometer was sluggish in action, and during the year it has been replaced by a thermo-electric junction consisting of a blackened copper disc with an attached iron wire. The new apparatus is very sensitive, five seconds' exposure to sunshine causing it to register, and with a photographic recording apparatus it promises to be an efficient quantitative sunshine-recorder.

The Committee for Comparing and Reducing Magnetic Observations report that they have recommended the Admiralty to establish a magnetic observatory at the Cape of Good Hope. Another committee presented an account of magnetic work done at Falmouth Observatory, of a character similar to that of Kew.

Prof. G. F. Fitzgerald introduced a subject which has hitherto been very slightly discussed—namely, the magnetic effects of electric charges moving over the earth's surface. Suppose equal and opposite electric charges originally concentrated at the poles to unite. Electric oscillations would be set up on the earth's surface whose period has been calculated by Prof. J. J. Thomson and Mr. Heaviside to be about one-seventeenth of a second. A suspended magnet with this period of swing would be disturbed by them. A similar disturbance on the sun's surface would have a period of 6½ seconds. Prof. Oliver Lodge has tried to detect the latter effect, but without success. Prof. Fitzgerald indicated another mode of oscillation, regarding the earth as a condenser with the surfaces of the upper atmosphere and of the crust as its coatings. The discharge of such a condenser would give rise to disturbances of one-tenth to one second period, depending on the thickness assumed for the non-conducting portion of the atmosphere. It was suggested that these disturbances be sought for by suspended small magnets having their periods of swing within these limits.

A very valuable set of tables showing the electro-chemical properties of various salts in aqueous solutions of different strengths was presented, having been drawn up by the Rev. T. C. Fitzpatrick. The tables include (1) specific gravity data—viz., percentage composition, molecular composition, specific gravity, and temperature; (2) electrical conductivity with its temperature coefficient, and specific molecular conductivity; (3) a table of migration data for each salt; (4) fluidity data, the reciprocal of the viscosity or fluid friction. These tables will be useful in estimating the resistance of liquids for practical purposes, as well as for theoretical investigations.

Prof. Oliver Lodge has been endeavouring to ascertain throughout the past two years whether a mechanical connection exists between ether and matter. This problem is of extreme importance in determining the exact nature of electrical actions, but its solution presents very great difficulties. Dr. Lodge has attacked it by examining whether the ether near a rapidly spinning body is set in motion or not. If it is, a beam of light travelling in the same direction as the body will be accelerated, while a similar beam travelling in the opposite direction will be retarded. In the experiment these two beams set out from the same source, travel in opposite directions along nearly the same path, and are then examined together by a telescope; any changes in their velocity would be indicated by a shift of the interference bands produced by them. The rotating body consisted of two parallel steel discs about a yard in diameter, mounted on the same vertical axis about an inch apart, and driven by an electric motor at about 3,000 revolutions per minute. After eliminating all disturbing causes, it was found that no effect was really produced on the beams, from which it is concluded that moving matter does not move the ether in its neighbourhood by any direct mechanical process. Dr. Lodge is of opinion that the interaction of ether and matter is always accompanied by electric or electro-magnetic stresses, and he thinks it just possible that the ether in a space between two oppositely charged discs would be moved along with the discs; although it does not move when they are not electrified. The result of this experiment will be watched with interest.

The subject of piezo-electricity, the development of electric polarity on compressing or distending a plate of crystal, has been occupying the attention of Lord Kelvin, who communicated a paper on the theory of it. He supposed it to be due to alteration in the mutual distances of oppositely charged atoms in neighbouring molecules; this is equivalent to altering the distance apart of the coatings of a charged condenser, which would change their potential difference. Lord Kelvin illustrated his theory by a "piezo-electric pile," a description of which was given in last week's number of this journal (page 277). Starting from the theory given by Lord Kelvin, the amount of the charge on each atom has been calculated by Prof. Chattock (*Phil. Mag.*, December, 1892), who finds it to agree with the value derived from electrolytic data.

Two papers on electric waves give accounts of experiments made under the direction of Prof. Hertz at Bonn. That of Mr. E. H. Barton depends on the fact, discovered by Herr von Geitler, that an electric wave travelling in the space between two parallel wires is partially reflected at places where the wires change in capacity, conductance, or distance apart. Let a length of thicker or thinner wire be placed in each of two similar long parallel wires. Waves set up at one end in the ordinary way (by means of a Hertz oscillator and secondary conductor) would reach the portion of different thickness. A part would be reflected and the rest transmitted. The latter would again suffer partial reflection on reaching the point where the conductor regained its original thickness. The interference of these reflected waves gives

rise to nodes and ventral segments, the positions of which have been traced by Mr. Barton, who aptly compares them to the phenomenon of Newton's rings in optics. The other paper, by Mr G. U. Yule, has for its object to determine the thickness of electrolyte necessary in order to completely absorb an electric wave passing between two parallel wires. The wires were arranged as in Mr. Barton's experiment, but were of the same thickness throughout. They were caused to pass down the whole length and through the bottom of a jar containing the electrolyte, and the smallest depth of electrolyte was noted which would suffice to absorb the waves passing into it. In this way Mr. Yule has shown that the electric resistances of electrolytes bear almost the same proportion to each other when measured for waves whose rate of alternation is a million per second, as they do for steady currents. He also established the high resistance of water for such rates of alternation. It will be remembered that Prof. J. J. Thomson obtained similar results some time ago, allowing the radiation from an oscillator to fall on and be absorbed by a layer of electrolyte. The present experiments differ from those of Prof. Thomson in that the waves are prevented from spreading in all directions, being constrained to move between the parallel wires.

To the electrical engineer one of the most important papers of the meeting was that of Prof. Rucker on the "Magnetic Shielding of Two Concentric Spherical Shells." The question of shielding electric railways so that their magnetic effects shall not disturb electrical instruments in their neighbourhood has attained to some degree of importance since objections were made to the passage of an electric railway near the Colleges in Exhibition-road, on the ground that it would disturb the instruments of their physical laboratories. Magnets moving on the cars would also disturb any telegraphic or telephonic systems in their neighbourhood unless the magnets are surrounded by some sort of screen. Prof. Rucker has obtained by a spherical harmonic analysis the magnetic force outside two concentric spherical shells due to any distribution of magnetism inside. The general equations are long and somewhat complicated, but special interest attaches to the case of a magnet at the centre of the shells. Regarding the shells as equivalent to a spherical shell of high permeability, with a "spherical" crack inside it, the screening effect is a maximum for a given mass of shell when the volume of the crack is the harmonic mean of the inside and outside volumes of the shell. This result will enable us to surround dynamos and motors with a far more efficient sheath than before. Prof. Fitzgerald was not so successful in an attempt to calculate the screening effect of a long cylinder, but had to be content with laying the equations for this case before the section. The papers of Prof. Fitzgerald, on "The Effect of a Hertzian Oscillation on Points in its Neighbourhood," and of Dr. Larmor, on "Magnetic Action on Light," were also of a mathematical character. In the latter attention was called to a difference in the views of Berlin and Gottingen physicists respecting the reflection of light from a magnet, and electromagnetic equations generally; and Dr. Larmor showed how the equations might be simplified so as to include only two terms, of which one corresponds to the Hall effect and the other to the rotation of plane of polarisation of light reflected from a magnet. Dr. Larmor's paper was regarded as of peculiar interest and importance by the mathematical physicists present, and was subsequently ordered to be printed *in extenso*.

In their report on the application of photography to meteorology, the committee have advanced a new theory respecting the ribbon structure shown by photographs of lightning discharges. They consider that a discharge may consist of several flashes in rapid succession along almost identical paths. If the air were still, the path marked out by the first flash would be followed by subsequent ones, and the photograph would present the appearance of a very narrow band; but with moving air the path of least resistance taken by the first flash becomes appreciably shifted before the second flash takes place. This flash, therefore, appears by the side of the first, but the two are not exactly coincident, thus causing the photograph to show a broad band.

The electrical world is indebted to the Electrical Standards Committee of the British Association for having at last secured a practically universal unit of resistance. The president referred in his inaugural address, and later in the report of this committee, to the fact that the Governments of France, Italy, Austria, Germany, and the United States had adopted the unit of resistance recommended by the committee to the English Board of Trade. The unit is obtained by taking a tube 106·3 centimetres long and of such a uniform cross-section that it is just filled by 14·4521 grammes of mercury when at 0deg. C. The resistance of the tube full of mercury is one unit. The original B.A. unit is ·9866 times the new one. The committee have obtained 21 copies of the unit or its multiples during the year, which Mr. Glazebrook will from time to time compare with the standard. As yet the new unit had not till recently received any name. Four were submitted to M. Mascart—namely, "international," "normal," "etalon," and "ohm de 1893." The B.A. committee prefer the first one, but would adopt any of the first three. The name "international ohm" has been agreed to. They have not come to any decision with respect to the name "henry," which the Chicago Congress has adopted for the unit of self-induction, but are understood generally to approve. Some condensers constructed 23 years ago by Dr. Muirhead have been retested, and their capacity differs only by 1 part in 5,000 from that assigned to them at the time they were made. We may conclude, therefore, that standard condensers do not alter in value with time.

The association's standard coils do not include submultiples of an ohm, and Prof. J. Viriamu Jones has been applying the method of Lorenz to construct standards of low resistance—such as would be useful in practice for measuring large currents. Lorenz's method consists in balancing the E.M.F. between the centre and edge of a copper disc spinning in the magnetic field of a coil conveying a current, against the potential difference between the ends of a resistance traversed by the current. The only data necessary are the speed of the disc and the mutual induction between the coil and disc, the latter of which may be calculated. The moving contact at the edge of the disc was made by a perforated tube, from which mercury under pressure oozed out. The speed was regulated by a stroboscopic circle and an electrically-driven fork, as in Lord Rayleigh's experiments by the same method.

Prof. Oliver Lodge described the design of a ballistic galvanometer intended for physiological work, but applicable to all purposes for which ballistic galvanometers are usually employed. He thought that in such instruments the long period of swing should be attained without lessening the sensitiveness by having an extremely light and highly magnetised needle, and by avoiding damping. He, therefore, proposed to make the moving parts as light as possible, at the same time reducing the surface so as to diminish the damping; the coils to be fairly small and numerous (say, four pairs), and each pair having a magnet at its centre. The magnets were to be made of pieces of very thin steel wire fastened to a disc nearly fitting the coil, to be rigidly fastened together as an astatic system, and suspended by a quartz fibre. As the moving parts usually include a mirror, which adds greatly to their weight, Prof. Lodge proposed to replace this by a light pointer, such as the sting of a bee, which could be viewed by a microscope having a graduated eye-piece. He believed biologists would like this plan, but he found that instrument makers fought shy of it, and greatly preferred the mirror. The only other requisite was a very weak controlling magnet, which might consist of two magnets opposing each other. An instrument made as nearly as possible on these lines had been constructed and was exhibited by Mr. F. H. Nalder, who stated that it was fully twice as sensitive as the ordinary ballistic galvanometers of the same resistance, and that its figure of merit could be still further increased.

A new feature in connection with the section this year was the exhibition of scientific apparatus and photographs in rooms adjoining the section. The Cambridge Scientific Instrument Company sent several instruments, among which was Callendar's platinum pyrometer for measuring the

temperature of a furnace by the alteration in resistance of a platinum wire exposed to its heat. Messrs. Nalder Bros. and Co. were represented by several instruments, including Prof. Ewing's magnetic curve-tracer, and Dr. Lodge's galvanometer, described above. They also sent an apparatus for comparing nearly equal resistances by Carey-Foster's method, which has the merit of being exceedingly compact. The ratio coils are both wound on one bobbin, so as to ensure their having the same temperature; a half turn of a circular commutator interchanges the two coils to be compared, and a short bridge wire is included on the same base. To give the instrument a wider range the bridge wire can be replaced by others of different thicknesses, the resistance of unit length of each being known. Mr. R. W. Paul exhibited electric measuring instruments of the d'Arsonval type for use near dynamos. Messrs. Pyke and Harris lent a small alternator and transformer of a size suitable for laboratory experiments; and Messrs. Newton and Co. showed electric lanterns and projection apparatus. Of the photographs, some by the Rev. F. J. Smith, called by him "Inductoscripts," were of great interest. They are produced by placing a coin (or indeed anything with a pattern on it and which is capable of conducting electricity) pattern downwards on the film of a photographic plate resting on a large metallic plate. The coin and metallic plate are then connected either to an induction coil or an electrical machine, and a spark is passed between them. On developing the photographic plate an image of the coin appears on it. In this way Mr. Smith has copied coins, copper-plates for engraving, and even leaves, after making them conductors. Bromide paper may be used instead of plates with equally good results.

The industry of Section A, whose sittings are the first to commence and the last to terminate, has been frequently commented on. This year, however, there were fewer papers than usual, and a Wednesday sitting was found to be unnecessary. The papers have been well discussed, and although there was nothing of a nature to cause excitement such as that occasioned by the preparation of fluorine or the narrative of a voyage to the Antarctic regions, yet the meetings of the section were certainly free from dulness to anyone understanding the subjects discussed, and they have been well attended throughout.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE I.

(Continued from page 283.)

Indicated and Effective Horse power.—In questions of power distribution, it is clear that it is the effective horse-power delivered at the crankshaft, and not the indicated horse power developed in the cylinder, which has to be considered. It is due to the difficulty of determining in most cases the mechanical efficiency of an engine that engineers have been content to reckon on the indicated horse power. It is true that the engine friction is not a very large fraction of the power developed in full load trials, nor does this fraction vary very greatly at full load for different engines. But it is erroneous to assume tacitly that the engine friction is, in all cases, a quantity of relatively little importance, or that it is immaterial whether the indicated or the effective horse-power is used in calculations.

Influence of Mechanical Efficiency on the Economy of Working with a Varying Load. The mechanical efficiency of steam engines, or the ratio of the effective to the indicated power at full load, is 0·8 to 0·85 for small engines, and may reach at least 0·9 for large engines. It is a little greater for non condensing than for condensing engines, and for simple than for compound. A triple-expansion engine, constructed by Messrs. McLaren, tested on a brake, gave 122 i.h.p., and 107 on the brake—an efficiency of 0·88. The loss of power due to engine friction is not very great or variable so long as the engines are worked at full load. It is quite otherwise, however, at light loads, and the extent to which this affects the economy of working has been overlooked.

Many experiments show that the engine friction is nearly the same at all loads. Suppose that at full load an engine gives 100 i.h.p. and 85 e.h.p. If the friction is constant, then for smaller loads the efficiency diminishes as shown in Table IV.

The steam and coal used depend on the indicated power—the work done on the effective power. The decrease of mechanical efficiency for light loads has a serious effect on the economy of working with a varying load.

* Howard Lectures delivered before the Society of Arts.

TABLE IV.—Mechanical Efficiency of Engines with Varying Load.

Indicated h.p.	Effective h.p.	Efficiency.
100	85	·85
75	60	·80
50	35	·70
25	10	·40

Careful experiments on mechanical efficiency with varying loads are not very numerous. It is useful, therefore, to give the results of some experiments on a Corliss engine of about 180 i.h.p. at full load. This engine was tried with a brake at Creusot, both condensing and non-condensing. It was found that the results agreed approximately with the following equations:

Condensing .... $T_e = 0·902\,T_i - 16$
Non condensing .... $T_e = 0·945\,T_i - 12$

equations which give results not differing greatly from those obtained by assuming the friction constant. The following are the calculated values of the efficiency.

TABLE V.—Mechanical Efficiency of Corliss Engine with Varying Load.

Actual effective power. / Power at full load.	Mechanical efficiency. Condensing.	Mechanical efficiency. Non-condensing.
1·0	·82	·86
·75	·79	·83
50	·74	·78
·25	·63	·67
·125	·48	·62

Influence of the Loss due to Back Pressure on the Economy of Steam-engine Working.—Besides engine friction, there is another waste of energy in the steam engine which has, to an even greater extent, been overlooked. The effective power is less than the indicated power by the engine friction; but the indicated power itself is less than the work done by the steam by the amount of work done against back pressure.

In condensing engines the back pressure is comparatively small, but in non-condensing engines the back pressure exceeds 15lb. per square inch. Its influence on economy, even at full load, is considerable, and at light loads it may become excessively great.

In engines working, as most engines do, at constant speed, the work against back pressure is nearly independent of the load.

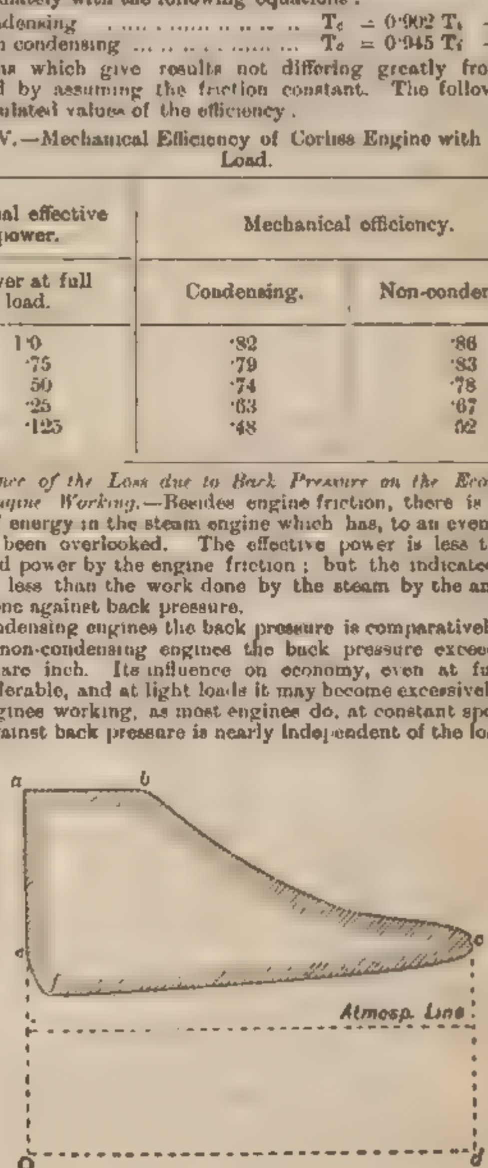

FIG. 5.

In interpreting an indicator diagram, Fig. 5, the total work done by the steam on the piston, called by some continental writers the absolute indicated work, is the area $O\,e\,a\,b\,c\,d$. The work afterwards wasted in overcoming back pressure is $O\,e\,f\,c\,d$. The difference is the effective work, $e\,a\,b\,c\,f$. The quantity of steam used depends on the absolute indicated work; the useful energy obtained on the effective indicated work. If the back pressure work is constant, it becomes a larger and larger fraction of the absolute work as the load on the engine is diminished.

Suppose, in a non condensing engine the work against back pressure is 20 per cent of the absolute indicated work of the steam at full load. Then for other loads the work is distributed thus:

TABLE VI.—Waste of Work due to Back Pressure.

Absolute indicated work of steam.	Work against back pressure.	Net or effective indicated work.
h.p.	h.p.	h.p.
125	25	100
75	25	50
50	25	25
37½	25	12½
25	25	0

Condensing Triple.

$$W = 112 + 13{\cdot}75 \text{ i.h.p.}$$
$$= 377 + 13{\cdot}75 \text{ e.h.p.}$$

If instead of calculating the total steam per hour, W, we calculate the steam per horse-power hour, we get results which, plotted like the previous diagrams, give rectangular hyperbolas, curves which agree closely with the theoretical curves for the case of varying pressure previously given. To show the great variation of steam consumption, these values are given in Tables VIII. and IX. for full load, half load, quarter load, and one-eighth load.

TABLE VIII.—Steam Consumption, Pounds per Indicated Horse-power and Pounds per Electrical Horse power Hour.

III. 100-e.h.p. engine	·65	29·5	23
IIIa. do. and one similar engine running at half speed...	·53	33·1	38

Increase of Steam Consumption Working with a Variable Load.—Captain Sankey has applied Mr. Willans's formula to find the steam consumption of one or more engines working against a variable load, as in an electric lighting station. He takes a normal mid winter load curve and examines how the necessary current could be supplied during the 24 hours (1) with one engine capable of exerting the maximum power required; (2) with smaller engines. He also considers the steam consumption when one additional engine is kept running at half speed as a stand by in case of accident. The results rearranged and a little modified are given in the preceding table. It is assumed, for convenience, that the maximum load is 500 e.h.p., and that the engines are non-condensing.

Influence of Irregular Working of the Boilers on the Expenditure of Fuel.—With a varying load the steam consumption, and consequently the fuel consumption also, is increased (1) in consequence of the decreased mechanical efficiency of the engines with light loads; (2) by the greater proportion the work expended in overcoming back pressure bears to the total work of the steam; (3) by the diminished thermal efficiency of the engine. But all these causes taken together do not explain fully the great fuel consumption in such cases as electric lighting stations. There is another very obvious cause of uneconomical working which cannot at present be estimated quantitatively for want of sufficient experimental investigation. With a very varying load, boilers must be put in steam and banked up alternatively, and the waste in getting up steam and allowing the boilers and brickwork to cool down again is no doubt considerable. This waste is at present unavoidable, except so far as means can be adopted to improve the load line.

Some tests, made by Prof. Kennedy at the Millbank street station of the Westminster Electric Supply Corporation, indicate pretty clearly a boiler waste additional to the engine waste. Dividing the day into three portions, he determined the fuel consumption, the feed water evaporated, and the indicated and electric horse power developed during each period. It will be seen that during the periods of light loading the fuel consumption per horse power hour is very large.

Perhaps the fairest way of considering the waste due to variable load will be to compare the mean consumption in the 24 hours with the consumption between 6 p.m. and midnight, when the load was heaviest. It will be seen that the mean steam consumption per electrical horse power hour was 24 per cent. greater than during the period of heavy load. But the mean consumption of coal per electrical horse power hour was 46 per cent. greater than during the period of heavy load. The difference of [illegible] per cent. must be attributed to waste at the boilers, due to irregular working. During the whole 24 hours the mean evaporation, in pounds of water per pound of coal, was only 85 per cent. of the evaporation during the period of maximum load (Table X).

(To be continued.)

EXPERIMENTS FOR IMPROVING THE CONSTRUCTION OF PRACTICAL STANDARDS FOR ELECTRICAL MEASUREMENTS.

Report of the committee, consisting of Prof. CAREY FOSTER (chairman), Lord KELVIN, Profs. AYRTON, J. PERRY, W. G. ADAMS, and Lord RAYLEIGH, Drs. O. J. LODGE, JOHN HOPKINSON, and A. MUIRHEAD, Messrs. W. H. PREECE and HERBERT TAYLOR, Profs. J. D. EVERETT, and A. SCHUSTER, Dr. J. A. FLEMING, Profs. G. F. FITZGERALD, G. CHRYSTAL, and J. J. THOMSON, Messrs. R. T. GLAZEBROOK (secretary), W. N. SHAW, Dr. J. T. BOTTOMLEY and T. C. FITZPATRICK, Prof. J. VIRIAMU JONES, Dr. G. JOHNSTONE STONEY, Prof. S. P. THOMPSON, and Mr. G. FORBES. (Presented to Section A of the British Association, September 19, 1893.)

The work of testing resistance coils at the Cavendish Laboratory has been continued. A table of the coils tested is given. They have all been "ohms," as defined by the resolution of the committee given in their last report, and since adopted by the Board of Trade Committee on Electrical Standards in the following form:

The resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass, of a constant cross-sectional area, and of a length of 106·3 centimetres, may be taken as one ohm. The relation between the B.A. unit and the ohm is the following:

One B.A. unit = ·9866 ohm.

* This coil has been tested before.

The resolutions adopted by the committee at Edinburgh were communicated to the Electrical Standards Committee of the Board of Trade. After consideration the Board of Trade Committee drew up an amended report, in harmony with the Edinburgh resolutions, for presentation to the president (see Appendix I.).

The resolutions were accepted at Edinburgh by Dr. von Helmholtz on behalf of Germany, while in France an official committee decided last June to adhere to the propositions of the Board of Trade. Austria and Italy are connected by treaty with Germany for telegraph purposes, and in consequence adopt the same units.

Tests have been made during the year on the 1-ohm and 10 ohm standards of the association. These are still being continued. The 100-ohm and 1,000-ohm standards have now been delivered, and the tests will be shortly proceeded with. Some experiments were made as to the amount of heating in the coils produced by the current used for testing. These are detailed in Appendix II. Further valuable information on this point is contained in Mr. Griffiths's paper on "The Value of the Mechanical Equivalent of Heat."*

The committee think it desirable that they should be in a position to complete the set of resistance standards of the association, and recommend, therefore, that they be reappointed, with a grant of £25, that Prof. G. Carey Foster be chairman, and Mr. R. T. Glazebrook secretary.

The committee have learned with pleasure from Mr. W. H. Preece, one of the English delegates to the International Congress of Electricians at Chicago, that the congress has accepted a series of resolutions defining the fundamental units practically identical with the Edinburgh resolutions. Thus these resolutions have now been accepted as a basis for legislation throughout the British Empire, the whole of Western Europe, and the United States of America.

* Phil. Trans., 1893.

The committee are also informed that the Chicago Congress have adopted the name "henry" for the unit of self induction

While looking with favour on this suggestion, they think desirable to postpone definite action until the official report of the congress has been received.

In March, M Mascart wrote to the secretary, asking the opinion of the committee as to a name for the standard of resistance defined at Edinburgh. A circular letter was issued inviting members of the committee to express their views on four names which had been suggested—viz, international, normal, etalon, or "ohm de 1893." After receiving replies to the circular from 12 members of the committee, the secretary wrote to Prof Mascart to the effect that the number of members who expressed a preference for the name "international" was greater than the number declaring in favour of any other name, but that he thought that the committee would accept whichever of the first three suggestions commended itself to the French committee appointed to deal with the matter.

During the year, Dr. Muirhead has remeasured his standard condenser. He now finds as the capacity of a condenser, constructed 23 years since, to represent 1 microfarad (B.A.U.), the value ·9888 microfarad.

APPENDIX I.

Supplementary Report of the Electrical Standards Committee of the Board of Trade.

To the Right Hon. A. J. Mundella, M P., President of the Board of Trade.

Subsequently to the presentation of our former report to Sir Michael Hicks Beach, in July, 1891, we were informed that it was probable that the German Government would shortly take steps to establish legal standards for use in connection with electrical supply, and that, with a view to secure complete agreement between the proposed standards in Germany and England, the director of the Physico technical Imperial Institute at Berlin, Prof. von Helmholtz, with certain of his assistants, proposed to visit England for the purpose of making exact comparisons between the units in use in the two countries, and of attending the meeting of the British Association which was to take place in August in Edinburgh.

Having regard to the importance of this communication, it appeared desirable that the Board of Trade should postpone the action recommended in our previous report until after Prof Helmholtz's visit.

That visit took place early in August, and there was a very full discussion of the whole subject at the meeting of the British Association in Edinburgh, at which several of our number were present. The meeting was also attended by Dr. Guillaume, of the Bureau International des Poids et Mesures, and Prof. Carhart, of the University of Michigan, U.S A., who were well qualified by their scientific attainments to represent the opinion of their respective countries.

It appeared from the discussion that a few comparatively slight modifications of the resolutions included in our previous report would tend to secure international agreement.

An extract from the report of the Electrical Standards Committee of the British Association embodying the results of this discussion was communicated to us by the secretary, and will be found in the appendix to this report.

Having carefully reconsidered the whole question in view of this communication, and having received the report of the sub committee mentioned in resolution 14 of our previous report, we now desire, for the resolutions contained in that report, to substitute the following

Resolutions.

1. That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by her Majesty in Council as Board of Trade standards.

2. That the magnitudes of the standards should be determined on the electromagnetic system of measurement with reference to the centimetre as unit of length, the gramme as unit of mass, and the second as unit of time, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.

3. That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.

4 That the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14 4521 grammes in mass of a constant cross sectional area, and of a length of 106 3 centimetres, may be adopted as one ohm.

5. That a material standard, constructed in solid metal, should be adopted as the standard ohm, and should from time to time be verified by comparison with a column of mercury of known dimensions.

6. That, for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordinary use, a limited number of copies should be constructed, which should be periodically compared with the standard ohm.

7. That resistances constructed in solid metal should be adopted as Board of Trade standards for multiples and sub-multiples of the ohm.

8. That the value of the standard of resistance constructed by a committee of the British Association for the Advancement of Science in the years 1863 and 1864, and known as the British Association unit, may be taken as ·9866 of the ohm.

9. That the standard of electrical current should be denominated *the ampere*, and should have the value one tenth (0·1) in terms of *the centimetre, gramme, and second.*

10. That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of one ampere

11. That an alternating current of one ampere shall mean a current such that the square root of the time average of the square of its strength at each instant in amperes is unity

12 That instruments constructed on the principle of the balance in which, by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights, should be adopted as the Board of Trade standards for the measurement of current, whether unvarying or alternating.

13 That the standard of electrical pressure should be denominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere.

13. That the electrical pressure at a temperature of 15deg. C. between the poles or electrodes of the voltaic cell known as Clark's cell, prepared in accordance with the specification attached to this report, may be taken as not differing from a pressure of 1 434 volt by more than 1 part in 1,000.

15. That an alternating pressure of one volt shall mean a pressure such that the square root of the time average of the square of its value at each instant in volts is unity.

16 That instruments constructed on the principle of Lord Kelvin's quadrant electrometer used idiostatically, and for high pressures, instruments on the principle of the balance, electrostatic forces being balanced against a known weight, should be adopted as Board of Trade standards for the measurement of pressure, whether unvarying or alternating.

November 29, 1892.

Specification Referred to in Resolution 10.

In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment and by noting this time the time average of the current, or if the current has been kept constant, the current itself can be deduced.

In employing the silver voltameter to measure currents of about one ampere, the following arrangements should be adopted. The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 centimetres in diameter, and from four to five centimetres in depth

The anode should be a plate of pure silver some 30 square centimetres in area, and two or three millimetres in thickness.

This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax.

The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

Method of Making a Measurement.

The platinum bowl is washed with nitric acid and distilled water dried by heat, and then left to cool in a desiccator. When thoroughly dry it is weighed carefully.

It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support, to which a binding screw is attached. This copper support must be insulated.

The anode is then immersed in the solution, so as to be well covered by it, and supported in that position; the connections to the rest of the circuit are made.

Contact is made at the key, noting the time of contact. The current is allowed to pass for not less than half an hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval.

The solution is now removed from the bowl and the deposit is washed with distilled water and left to soak for at least six hours. It is then rinsed successively with distilled water and absolute alcohol, and dried in a hot air bath at a temperature of about 160deg. C After cooling in a desiccator it is weighed again. The gain in weight gives the silver deposited.

To find the current in amperes, this weight, expressed in grammes, must be divided by the number of seconds during which the current has been passed and by ·001118.

The result will be the time average of the current, if during the interval the current has varied

In determining by this method the constant of an instrument, the current should be kept as nearly constant as possible and the readings of the instrument taken at frequent observed intervals of time. These observations give a curve from which the reading corresponding to the mean current (time-average of the current)

can be found. The current, as calculated by the voltameter, corresponds to this reading.

SPECIFICATION REFERRED TO IN RESOLUTION 14.

Definition of the Cell.

The cell consists of zinc and mercury in a saturated solution of zinc sulphate and mercurous sulphate in water, prepared with mercurous sulphate in excess, and is conveniently contained in a cylindrical glass vessel.

Preparation of the Materials.

1. *The Mercury.*—To secure purity it should be first treated with acid in the usual manner, and subsequently distilled in vacuo.

2. *The Zinc.*—Take a portion of a rod of pure redistilled zinc, solder to one end a piece of copper wire, clean the whole with glass paper, carefully removing any loose pieces of the zinc. Just before making up the cell dip the zinc into dilute sulphuric acid, wash with distilled water, and dry with a clean cloth or filter paper.

3. *The Zinc Sulphate Solution.*—Prepare a saturated solution of pure ("pure recrystallised") zinc sulphate by mixing in a flask of distilled water with nearly twice its weight of crystals of pure zinc sulphate, and adding zinc oxide in the proportion of about 2 per cent. by weight of the zinc sulphate crystals to neutralise any free acid.* The crystals should be dissolved with the aid of a gentle heat, but the temperature to which the solution is raised should not exceed 30deg. C. Mercurous sulphate, treated as described in 4, should be added in the proportion of about 12 per cent. by weight of the zinc sulphate crystals, and the solution filtered while still warm into a stock bottle. Crystals should form as it cools.

4. *The Mercurous Sulphate.*—Take mercurous sulphate, purchased as pure, and wash it thoroughly with cold distilled water by agitation in a bottle; drain off the water and repeat the process at least twice.* After the last washing drain off as much of the water as possible.

Mix the washed mercurous sulphate with the zinc sulphate solution, adding sufficient crystals of zinc sulphate from the stock bottle to ensure saturation, and a small quantity of pure mercury. Shake these up well together to form a paste of the consistence of cream. Heat the paste, but not above a temperature of 30deg. C. Keep the paste for an hour at this temperature, agitating it from time to time, then allow it to cool; continue to shake it occasionally while it is cooling. Crystals of zinc sulphate should then be distinctly visible, and should be distributed throughout the mass; if this is not the case, add more crystals from the stock bottle, and repeat the whole process.

The method ensures the formation of a saturated solution of zinc and mercurous sulphates in water.

Contact is made with the mercury by means of a platinum wire about No. 22 gauge. This is protected from contact with the other materials of the cell by being sealed into a glass tube. The ends of the wire project from the ends of the tube; one end forms the terminal, the other end and a portion of the glass tube dip into the mercury.

To Set up the Cell.

The cell may conveniently be set up in a small test tube of about two centimetres diameter, and six or seven centimetres deep. Place the mercury in the bottom of this tube filling it to a depth of, say, 1·5 centimetre. Cut a cork about ·5 centimetre thick to fit the tube; at one side of the cork bore a hole, through which the zinc rod can pass tightly; at the other side bore another hole for the glass tube which covers the platinum wire; at the edge of the cork cut a nick, through which the air can pass when the cork is pushed into the tube. Wash the cork thoroughly with warm water, and leave it to soak in water for some hours before use. Pass the zinc rod about one centimetre through the cork.

Clean the glass tube and platinum wire carefully, then heat the exposed end of the platinum red hot and insert it in the mercury in the test tube, taking care that the whole of the exposed platinum is covered.

Shake up the paste and introduce it without contact with the upper part of the walls of the test tube, filling the tube above the mercury to a depth of rather more than two centimetres.

Then insert the cork and zinc rod, passing the glass tube through the hole prepared for it. Push the cork gently down until its lower surface is nearly in contact with the liquid. The air will thus be nearly all expelled, and the cell should be left in this condition for at least 24 hours before sealing, which should be done as follows:

Melt some marine glue until it is fluid enough to pour by its own weight, and pour it into the test tube above the cork, using sufficient to cover completely the zinc and soldering. The glass tube should project above the top of the marine glue.

The cell thus set up may be mounted in any desirable manner. It is convenient to arrange the mounting so that the cell may be immersed in a water bath up to the level of, say, the upper surface of the cork. Its temperature can then be determined more accurately than is possible when the cell is in air.

In using the cell sudden variations of temperature should as far as possible be avoided.

Notes.

The Zinc Sulphate Solution.—The object to be attained is the preparation of a neutral solution of pure zinc sulphate saturated with $ZnSO_4 \cdot 7H_2O$.

At temperatures above 30deg. C. the zinc sulphate may crystallise out in another form. To avoid this 30deg. C. should be the upper limit of temperature. At this temperature water will dissolve about 1·9 time its weight of the crystals. If any of the crystals put in remain undissolved, they will be removed by the filtration.

* See Notes.

The amount of zinc oxide required depends on the acidity of the solution, but 2 per cent. will in all cases which will arise in practice with reasonably good zinc sulphate be ample. Another rule would be to add the zinc oxide gradually until the solution became slightly milky. The solution when put into the cell should not contain any free zinc oxide. If it does then when mixed with the mercurous sulphate, zinc sulphate and mercurous oxide are formed. The latter may be deposited on the zinc, and affect the E.M.F. of the cell. The difficulty is avoided by adding, as described, about 12 per cent. of mercurous sulphate before filtration. This is more than sufficient to combine with the whole of the zinc oxide originally put in if it all remains free. The mercurous oxide formed, together with any undissolved mercurous sulphate, is removed by the filtration.

The Mercurous Sulphate.—The treatment of the mercurous sulphate has for its object the removal of any mercuric sulphate, which is often present as an impurity.

Mercuric sulphate decomposes in the presence of water into an acid and a basic sulphate. The latter is a yellow substance—turpeth mineral—practically insoluble in water; its presence, at any rate in moderate quantities, has no effect on the cell. If, however, it is formed the acid sulphate is formed also. This is soluble in water, and the acid produced affects the E.M.F. The object of the washings is to dissolve and remove this acid sulphate, and for this purpose the three washings described in the specification will in nearly all cases suffice. If, however, a great deal of the turpeth mineral is formed it shows that there is a great deal of the acid sulphate present, and it will then be wiser to obtain a fresh sample of mercurous sulphate rather than to try by repeated washings to get rid of all the acid.

The free mercury helps in the process of removing the acid, for the acid mercuric sulphate attacks it, forming mercurous sulphate and acid, which is washed away.

The cell may be sealed in a more permanent manner by coating the marine glue, when it is set, with a solution of sodium silicate and leaving it to harden.

APPENDIX.

August 12th, 1892.

Dear Sir,—I am desired by the Electrical Standards Committee of the British Association to communicate to the Electrical Standards Committee of the Board of Trade the enclosed extract from their report made to the Association on August 9th, 1892.

I remain, yours faithfully,
(Signed) R. T. GLAZEBROOK,
Secretary, Electrical Standards Committee
of the British Association.

To Sir Thomas Blomefield,
Secretary, Electrical Standards Committee
of the Board of Trade.

EXTRACT FROM THE REPORT OF THE ELECTRICAL STANDARDS COMMITTEE OF THE ASSOCIATION, AUGUST 9TH, 1892.

The following resolutions were agreed to:

1. That the resistance of a specified column of mercury be adopted as the practical unit of resistance.

2. That 14·4521 grammes of mercury in the form of a column of uniform cross section 106·3 centimetres in length at 0deg. C. be the specified column.

3. That standards in mercury or solid metal having the same resistance as this column be made and deposited as standards of resistance for industrial purposes.

4. That such standards be periodically compared with each other, and also that their values be redetermined at intervals in terms of a freshly set up column of mercury.

It was further agreed that these resolutions be communicated to the Electrical Standards Committee of the Board of Trade.

With regard to the units of current and E.M.F. it was agreed that the number ·001118 should be adopted as the number of grammes of silver deposited per second from a neutral solution of nitrate of silver by a current of one ampere, and the value 1·434 as the E.M.F. in volts of a Clark cell at 15deg. C.

Dr. von Helmholtz expressed his full concurrence in these decisions, which are, as he informed the committee, in accord with the recommendations which have already been laid by the Curatorium of the Reichsanstalt, as well as by himself, before the German Government.

APPENDIX II.

Experiments on the Effects of the Heating produced in the Coils by the Currents used in Testing. By R. T. GLAZEBROOK.

Various circumstances (notably the experiments of Mr. Griffiths*) had made it appear probable that the heating effect in the coils produced by the current used in making the resistance test might be sufficient to affect the results of the tests. Some experiments were made to examine the point directly.

The resistance of a coil of 100 ohms (nominal value) was measured in the usual way—*i.e.*, by making a Wheatstone bridge of four coils whose nominal values were 1, 10, 10, and 100 ohms. If the coils had been accurate there would have been a balance; as it was, one of the 10 ohm coils needed to be shunted, and the adjustment was made by determining the value of the shunt when no current passed through the galvanometer.

As the current in the battery circuit was increased by varying the number of cells this shunt decreased in value, showing that the effect of the heating was to produce an apparent diminution

* *Phil. Trans.*, 1893.

of the resistance of the 1,000-ohm coil. This, of course, is as would be anticipated, for ten-elevenths of the current goes through the 1-ohm and one of the 10-ohm coils, the remaining one-eleventh goes through the 10-ohm and the 100-ohm. The rise of temperature will clearly be greatest in the first 10-ohm coil, and to counterbalance the increase in resistance produced thereby it becomes necessary to reduce the shunt. The following readings were obtained:

Current in amperes.	Shunt in 1,000 ohms.	Correcting factor.
·06	32·5	1·00028
·09	32·5	·00031
·12	*30	·00033
·14	30·5	·00033
·15	29·5	·00034

* Only one observation at this current was made; the others are the mean of several.

The true value of the 100 ohm is given by taking the product of the values of the two 10-ohm coils at the temperature of the observations, dividing by the value of the 1-ohm and multiplying by a factor representing the effect of the shunt.

During the above observations the temperatures remained steady, the factor changed from 1·00028 to 1·00034. Thus the resistance of the 100-ohm coil changed by ·031 – ·028, or ·006 ohm.

The apparatus was not sensitive with a smaller current; the effect, however, will vary as the square of the current and since trebling the current produces so small a change, we may infer that the total effect is itself small.

Another coil gave the following results:

Current in amperes.	Shunt in 1,000 ohms.	Correcting factor.
·05	48	1·000208
·09	45	·000222
·12	43	·000233
·14	41	·000244
·15	40	·000250

indicating a change in the measured resistance of ·0042 ohm on 100 ohms.

It is clear, therefore, that the effect of heating is small, though appreciable when currents approaching ·15 ampere are used.

ELECTRIC LIGHTING OF PETERBOROUGH.

We have received a copy of the report on electric lighting presented to the Town Council of Peterborough by Mr. J. C. Gill, A.M.I.C.E., the waterworks engineer to the Corporation. The report, which is addressed by Mr. Gill to the mayor, aldermen, and councillors, is as follows:

In accordance with your instructions, I have the pleasure to submit for your consideration the following report upon the application now before you of the Midland House to House Electricity Company for your consent to supply electricity within the borough of Peterborough.

Mode of Procedure.—Before going into the general question of the advisability of the Corporation themselves applying for a provisional order, it may be well to point out the mode of procedure to be adopted in making such application. It is laid down by law that "the application must be made in pursuance of a resolution passed at a special meeting of the local authority, after one month's previous notice of the same, and of the purpose thereof. The notice of application must be published in the months of October and November in two successive weeks in a local paper, and once in the *London Gazette*. The plans, etc., must be deposited on or before the 30th November with the clerk of the peace of the county and with the Board of Trade." It will thus be seen that with the month's notice before the meeting, and the advertisements after, as well as the preparation of the plans, etc., seven or eight weeks is the shortest time in which the regulations can be complied with; and in order to have all the requirements completed by November 30, the Council should decide upon its action in September, or, at the latest, early in October.

Area to be Lighted.—If the Corporation decide to apply for a provisional order the whole of the borough would be the area over which the powers would extend, but a "compulsory area," to be lighted within two years from the confirmation of the order, must be scheduled. This area would be the central portion of the town, and the mains would be extended outside its boundaries as required. The compulsory area may be large or small, at the will of the Council, but I would recommend the following streets as being suitable, viz., Westgate, Midgate, Long causeway, Market place, Church street, Cowgate, Queen street, Exchange street, Cumbergate, Cross street, Priestgate, Wentworth street, Narrow street, Bridge street, Bridge, and Bridge place.

Estimate of Cost.—In designing a central station for the supply of electricity, it is necessary to make provision for future extensions, and the first installation is thereby rendered more costly than if it were complete in itself. The buildings would provide for these future requirements, and in the buildings so designed I would recommend plant being erected capable of maintaining an output of 180,000 watts—equal to a constant lighting power of 51,500 candles. The system most suitable for supplying Peterborough is by continuous current at low pressure, and in my estimate I have adopted this system with accumulators. It is not the cheapest system, but for compact areas it is the best. I have provided for three compound steam engines, each driving a dynamo; and any two of these sets would be able to produce the current mentioned, while the third set was lying by. The total cost of buildings, engines, dynamos, accumulators, mains, switchboards and instruments required for making this installation complete I estimate at £12,500. The annual cost of maintenance when in full work, employing a working staff of nine hands and consuming 300 tons of coal per annum, would be (including management and office expenses) about £1,091, and adding interest on capital at the rate of 5 per cent. an annual return of £1,716 would be required.

Estimate of Income.—For the purpose of this estimate I have assumed that the charge to be made for current will be at the rate of 6d. per unit. At this price it will be necessary to sell 69,000 units per annum to make a return of 5 per cent. on the capital outlay, and pay the full working expenses. In Peterborough the consumption would probably average 30 units for each 16-c.p. incandescent lamp, and, therefore, it would be necessary to have 2,300 lamps connected. I believe, from enquiries I have made, that this number of lights would be subscribed for within a reasonable time, and that in a few years the electricity works would be earning such profits as to make them a very valuable property. With regard to this estimate of income, it must be borne in mind that until the lamps specified are at work the annual expenditure will not be nearly so much as stated. Half the staff and half the coal would suffice for supplying 1,200 lamps, and with this number only the works should pay their way. Then when the number of 2,300 is reached the maximum expenditure, with 5 per cent. interest, will be returned, and from this point onwards the income from additional lamps will be nearly all clear profit.

Cost Compared with Gas.—Electricity is usually sold by the Board of Trade unit, which is thus defined by Act of Parliament: "The expression 'unit' shall mean the energy contained in a current of 1,000 amperes flowing under an E.M.F. of one volt during one hour." One Board of Trade unit (or "kilowatt," as it is sometimes called), will keep an ordinary 10-c.p. incandescent lamp alight for 30 hours, or it will keep 30 of such lamps alight for one hour. The charge per unit varies in different towns from 4½d. to 8d., and could doubtless be sold in Peterborough at 6d. Taking, then, the cost of electric current at 6d. per unit, a 10-c.p. incandescent lamp would cost one-fifth of a penny per hour, which is the cost of a 5ft. gas burner at 3s. 4d. per 1,000 cubic feet. Every 5ft. gas burner could therefore be replaced with a 10-c.p. electric lamp at the same cost for current as paid for gas. Too much importance should not be attached to the relative prices of gas and electricity, because the quality of the commodity is in no way comparable. A great demand has been found for the electric light where gas of high quality is supplied at 2s. 2d. per 1,000ft., and where, consequently, the cost of electric lighting is very much higher than that of gas lighting.

Prospects of Cheaper Lighting.—There is a widespread idea that the plant for generating electricity is growing less costly year by year. This is not so. Buildings, boilers, steam engines, dynamos, and cables all cost as much now as they did when I prepared an estimate for you three years ago, and will probably cost as much three years hence. It is the current that has been cheapened, and that because of the increased output. When the quantity of units generated by the same plant is doubled, the cost per unit is considerably reduced, and can be sold at a less price. Thus the stations that have been running for some years and have got their plant working nearer to its full load, can bring down their charges from time to time, and in this way only is the generation of electricity becoming cheaper. The manufacture of all appliances used in central station works is now free and open, excepting only incandescent lamps, and in three months' time lampmaking will also be a free industry. There is therefore nothing to be gained by waiting, but, on the other hand, the sooner the works are in operation the sooner will they be earning a profit. The free trade in lamps will probably reduce the cost of electric light to the consumer, for besides getting the lamps at about one-third their present price, lamps are offered for delivery in November which are much more economical in the amount of current required per candle power.

Conclusion.—There is undoubtedly a strong desire amongst the commercial community of the city to adopt the electric light, and this is evidently the outcome of seeing the advantages derived from using electricity in other towns. There is also sufficient evidence that the local authority is the proper body to undertake the monopoly of supply. The Board of Trade regulations, very properly, make it impossible to have competition, but they give the local authority option of undertaking the supply themselves before granting powers to any company. Local authorities for some years held aloof from electric lighting, declining to go into any speculative business with ratepayers' money, and out of the first £4,500,000 invested in this industry only £474,000 belonged to local authorities. Now, however, the local authorities have realised that the supplying of electricity is a sound and profitable business, and the proportions of money expended are reversed, for out of works recently decided upon in 23 towns, costing in all £821,000, £796,000 are provided by the local authorities and only £25,000 by companies. The advantages of having any electricity supply works that may be established in Peterborough in your own hands are too obvious, and have been too often discussed to need recapitulating here, but I might point out that obtaining a provisional order does not bind you to carry out the powers granted, as the order may, if desirable, be afterwards transferred to a company. I am, however, so strongly convinced that the future of electricity supply undertakings will be profitable, that I feel justi-

fied in advising you to obtain the necessary powers in the ensuing session, and then proceed with the erection of some such central station as I have described. If, however, you should think the city would be better served by a company than the Corporation, I can safely say that you may, with every confidence as to the quality of work, allow powers to be taken by the company now seeking your consent. But if this is done, the company will be absolutely masters of the situation for 42 years, and I feel sure that a little consideration will show you that it must be for the benefit of the city that the Corporation should keep in their own hands the supply of electricity for all purposes. The successes attending municipal electricity works indicate clearly that there is everywhere a demand for this clean and wholesome light, and there is every reason to believe that when electricity works have been established in a town for 15 or 20 years, they will have obtained the same great value, as an investment, that gas and water works holds to-day.

For the reasons given in this report I submit (1) that the time has now come when the Town Council should decide either to apply for a provisional order themselves, or give their consent to the application of a company; (2) that in the best interests of the ratepayers they should obtain powers, and carry out electricity supply works themselves; (3) that they should commence with the central portion of the town, and instal a plant of about £12,500 capital cost.

ELECTRIC LIGHTING SCHEME FOR MONMOUTH.

In our issues of the 8th and 15th inst. we referred to the subjects of electric lighting and drainage as being under the consideration of the Monmouth Town Council, and to certain reports sent in to the latter authority. These reports were considered at a meeting of the Council on Friday, when the Mayor (Mr. W. Honeyfield) presided. The **Mayor** stated that at their last meeting he was authorised to form a small committee to examine the scheme foreshadowed and the statements he then made. This committee had met the electrical and sanitary engineers on the following Saturday, when instructions were given to examine and report upon the points put before them, and, if found practicable, to estimate for the cost. He would read their reports, and to enable them to consider the same ready for that day, he had made those extracts which were printed and distributed among them some days since. They had thus had an opportunity of considering the figures, and the scheme their committee recommended was the complete one, combining sewerage with the public and private lighting. The Mayor then read the following report:

REPORT OF THE BRUSH ELECTRICAL ENGINEERING COMPANY.

Our Mr. Dawbarn having inspected your borough and carefully examined local conditions affecting the question of electric lighting, we are now in a position to hand you herewith our report and suggestions as to the cost of (a) substituting 16 c.p. incandescent lamps for 95 gas lamps in existing lanterns belonging to your Corporation placed as at present; (b) extra for 11 additional lamps to replace oil lamps; (c) extra for installing plant large enough to maintain at one time 500 16 c.p. incandescent lamps for private consumers in addition to the whole of the street lamps; (d) auxiliary steam plant (equal to c), with spare dynamo, etc., as a stand-by to meet any emergency.

Power.—We thoroughly endorse the suggestion of yourself and Mr. Latley of utilising the natural power at your disposal, viz., the River Wye now running to waste, and have estimated accordingly. In Scheme A a turbine would be provided to develop 11 h.p., which would drive the sewage pump by day and the dynamo by night, maintaining the 100 or so street lamps. Under Scheme C we should require to develop 60 h.p., as against, say, 11 for the street lighting alone. The power we propose to obtain by means of two turbines, each to develop 30 h.p., which would together work upon the main shafting during the period of heavy load, say, from dusk to midnight, when one of them would be disconnected, as the other would be large enough to do all that would be required to meet the night load, including the street and private lighting, or the day load, comprising the sewage pumping, as well as any private lamps that might be alight in dark corners, etc. We do not propose at this stage to trouble you with minute details, but we may inform you that our estimates have been got out in complete detail, so that we shall be able to afford you any further information you may require at a later date without difficulty.

Alternator.—We may, however, be allowed to draw your attention to our Mordey Victoria alternator, which is the machine we recommend for your adoption. It is remarkable both for its simplicity of construction and its extremely high efficiency. We submit illustrations and a pamphlet describing our alternate current transformer system, which may be of interest. The usual pressure at which we work on the mains is 2,000 volts, but in this instance we propose only 1,000 volts.

Street Lamps.—The street lamps would be arranged in groups of 10 in series across the high pressure mains.

Private Lighting.—The private lighting would be effected by means of local transformers, to be placed either under the pavements, just outside the shop, or group of shops, or residences to be lighted, or in the basement of one of them. The arrangement of cables in our Scheme C admits of any private demand for incandescent lamps being met in the following streets to the extent of fully 500 16-c.p. lamps in all, without further outlay in mains: Wye Bridge-street, St. James's-street, Whitecross-street, Monk-street (as far as Priory-street), Church-street, Priory-street (from Agincourt-square to Market House), Agincourt-square, Monnow-street, St. Thomas's-square.

Transformers.—The transformer contains absolutely no mechanism, is enclosed in a watertight cast iron case, and is of extremely small dimensions. For instance, a 100-light transformer occupies a space not exceeding 2ft. × 1ft. × 1ft.; consequently there is no difficulty whatever experienced in actual working in disposing of these transformers conveniently for the lighting they control. The function of the transformer is to convert the pressure of 1,000 volts on the mains to 100 volts, which is suitable for private lighting and is absolutely harmless.

Mains.—The mains would be well insulated, sheathed with lead, further protected by taping, coated with special preservative compound, and laid directly in the ground in trenches provided by you. The above applies to the Schemes A and B, and to the small 10-light group conductors for the street lighting in Scheme C. The high pressure mains in Scheme C would, however, be drawn into iron pipes so as to admit of extension hereafter by drawing in larger cables in order to meet a growing demand from private consumers.

Auxiliary Plant.—If you undertake private lighting it will be absolutely necessary to provide against any possibility of interruption to the lighting, say through flood, which might prevent the turbines from working to their full advantage. We therefore quote under this section for spare plant, consisting of a vertical compound steam engine, locomotive boiler, and a spare alternator complete. We also provide a combination of fast and loose pulleys and clutches, so that the engine or either dynamo can be disconnected or connected to the main shafting at will. You will please understand that our tender does not include any building to accommodate the machinery, foundations for same, or cutting a canal for water supplied to turbines or race from them to the river, nor the construction of any works that may be required in the river itself. We are of opinion, after carefully examining the conditions, that a weir is not necessary, but it is possible that you may find it advantageous hereafter to construct a rough boulder type of weir for a few yards into the river, but this, if required at all, would be a trifling matter.

[Then follows a statement upon which the Corporation conclude that, while Mr. Latley's sewage scheme alone would cost £9,817 (adding £1,317 to the original cost for contingencies and fees) with an added annual cost of £150. 10s., which, allowing for repayment of principal and interest by 30 equal instalments at 3½ per cent., would necessitate a rate of 8½d. in the pound; in connection with public lighting, a rate of 7¾d. would only be required; and, further, by uniting the public and private lighting with the scheme, a rate at 5d. in the pound is estimated to meet the outlay. These facts are derived from carefully-prepared estimates as to expenses and anticipated revenue.]

The above estimates contain ample margins, and there is no reason whatever why your actual working expenses should exceed these amounts. You may therefore safely look to the larger plant to more than cover the working cost of your sewage scheme and leave a fair margin of profit. We desire to draw your attention to the fact that if you propose to take up your own powers for private lighting, it will be necessary for you to lodge your application to the Board of Trade before November 21 next in order to secure a provisional order in the ensuing session.

The **Mayor** then read the report by Mr. Latley on the sewerage question, and also a supplementary report, from which we abstract the following:

"I have seen the figures and calculations of Mr. Dawbarn compiled for the Brush Electrical Engineering Company, and so far as I am in a position to offer an opinion they appear to me to be correct. Having approved in general terms the mechanical arrangements which I understand are necessary for the proper and efficient carrying out of the scheme proposed by the Brush Electrical Engineering Company, I have to lay before you the following estimate. [Then follows estimate agreeing with that previously referred to.] It will be within your recollection that my preliminary estimate for the sewerage scheme was £8,500, but if the scheme as laid before you by the Brush Electrical Engineering Company is carried out in conjunction with my sewage scheme, there would be a reduction of from £800 to £1,000. I have carefully looked through the maintenance estimates of this company, and it appears that they show a profit which would cover the working expenses of the sewage scheme. In the event of your adopting the street-lighting scheme only, the expense of the waterway which is included in my sewage scheme would have to be increased to the extent of about £700.

Continuing, the **Mayor** said the figures given in the report showed a very favourable balance to the credit of the proposed scheme, but the question which arose in their minds, and in those of the ratepayers was, were the amounts reliable? He had heard frequently the opinion expressed that it would be a good thing if the thing could be done, but there seemed rather a doubt in the minds of the public, not as to its desirability, but possibility. He was firmly of opinion that the estimates given were fairly correct, and his ideas of its feasibility were confirmed by every enquiry. The figures of the electrical portion of the scheme were by the Brush Electrical Company, one of the most important companies in the kingdom in that branch of engineering, and were not an approximate estimate, but a tender for which they are prepared to do the work and guarantee its working. Those referring to the sewage part are by Mr. Latley, and are based upon work of the same kind in hand, and being carried out at the present time. He concluded his remarks with formally proposing the adoption of the report.

Councillor Cossens seconded the motion, which, after some discussion, was carried.

BUSINESS NOTES.

Coventry.—The Electric Light Committee of the Town Council has been established on a permanent basis.

Directory.—A new edition of the directory of the National Telephone Company for Scotland has just been issued.

Castleford (Yorks.).—The question of lighting the town by electricity is at present under the consideration of the Local Board.

Cork.—An electric light installation has been put up by Mr. Percival, of Cork, at the offices connected with Lady's Well Brewery, Cork.

A New Arc Lamp.—A new arc lamp, devised by Mr. H. Tipping, M.I.M.E., is being introduced by the Crown Electric Light Company, 80, Queen Victoria street.

St. Saviour's, Southwark.—The surveyor to the Board of Works has complained of inconvenience caused by electric lighting companies breaking up the asphalted thoroughfares.

Appointments Vacant.—The Bristol Corporation, as will be seen from our advertisement columns, require three assistant engineers for the municipal electric lighting station.

Fire Alarms.—The attention of the London County Council is to be directed by the Wandsworth Local Board to the insufficiency of fire alarms in the parishes of Tooting and Streatham.

Marchant, Young, and Co., Limited.—This Company has been registered, with a capital of £4,000 in £1 shares, to establish and carry on the business of electrical and mechanical engineers.

Bournemouth.—A central telephone is to be fixed in the hall of the Municipal Buildings connected with the town clerk's, surveyor's, and sanitary inspector's offices. The rent will be £3 yearly.

Ryde.—The Town Council have resolved to apply for power to supply public or private lighting by electricity, and to get permission to borrow and raise the amount required for the electric lighting.

Lewisham.—The Works Committee of the District Board have under consideration the question as to whether the Crystal Palace District Electric Supply Company shall light the public streets by electricity.

Southport.—A member of the Town Council has decided to defray the cost of installing the electric light in the church of St. Simon and St. Jude immediately on the Corporation supply being available.

Copper.—Copper is still quiet, with a moderate demand both for electrical purposes and for marine engineering. In the Newcastle district tough copper varies from £46 to £46. 10s. according to quantities needed.

Bristol.—The Board of Guardians have received eight tenders for the electric light installation at St. Peter's Hospital, and that of Messrs. Willway and Sons, of St. Augustine's-parade, for £28. 9s. 6d., has been accepted.

Anglo American Telegraph Company.—The Directors have declared an interim dividend for the quarter ended September 30 of 12s. 6d. per cent. on the ordinary stock, and 25s. per cent. on the preferred stock, less income tax.

Mersey.—The Mersey Docks and Harbour Board have confirmed the recommendation of the Docks and Quays Committee to provide an electric light at the south side of the entrance to the Morpeth Lock, at an estimated cost of £200.

City of London Union.—The House Committee have had referred to them for consideration and report the question of laying on the electric light at the infirmary at Bow, where there is a large number of patients in bed night and day.

Chichester.—The Lighting Committee of the Town Council have reported the appointment of a sub-committee to interview the gas company's representatives, and that they have considered the question of electric lighting, but have not yet arrived at a decision.

Watford.—At a meeting of the Local Board last week, the clerk asked for a committee to be appointed to help him to prepare the necessary notices with regard to the application for a provisional order for electric light. Messrs. Lake and Andrews were appointed.

Appointment.—We understand that Mr. T. H. Aldridge has obtained an appointment with the Grand Junction Canal works at their pumping station at Tring. He qualified himself for the post in the works of Mr. Ronald A. Scott, M.R.I., Acton-hill, London, W.

French Telephone Company.—With regard to the recent dissolution of the Société Générale des Téléphones, it is announced that the scheme for the reconstruction of the Company has now been completed, and that it will be laid before the shareholders shortly for their approval.

South Africa.—The South African Public Works Corporation, Limited, comprises among its signatories the firms of Messrs. Black, Hawthorne, and Co., Gateshead; the Gloucester Railway Carriage and Waggon Company, Limited; and Messrs. Easton and Anderson, of Erith.

City and South London Railway Company.—The receipts for the week ending September 24 were £773, against £768 for the same period last year, or an increase of £5. The total receipts for the second half year of 1893 show an increase of £445 over those for the corresponding period of 1892.

Rawmarsh.—The Local Board have decided to reduce the price of gas. Before doing so, at a meeting last week, Mr. Spick said that there was a probability of their having the electric light in the district before long, and he thought it would be to the interest of the Board to make a reduction as soon as possible.

Electro Protector Syndicate, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to adopt an agreement, made between R. Jewell of the one part and C. O. Greenwell, on behalf of this Company, of the other part, and to carry on business as electricians, mechanical engineers, etc.

Bolton.—The work of preparing the site in Spa-road for the proposed electric lighting depôt has been commenced this week, and is being rapidly pushed forward under the superintendence of Messrs. Hinnell and Murphy, architects, and Mr. Rider, electrical engineer. The laying of the mains will be proceeded with as quickly as possible.

Eastern Telegraph Company.—This Company announce the payment on October 13 of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum, on the preference shares for the quarter ending September 30, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended June 30.

Blackpool.—What is termed an "electrical *fête*" is to take place in a few days. At the electric lighting station all the dynamos for supplying the current for the arc lamps are now in readiness for running, and the electricity generated by one is being utilised for the arc lamps at the Winter Gardens. The total number of lamps to be erected along the Promenade is 73.

Guildford.—The Board of Guardians have referred to the House Committee a letter from the town clerk of Guildford, stating that the Council would have no objection to the telephonic connection of the union workhouse and the borough police station on condition that the whole of the expense was defrayed by the Guardians, and that an undertaking was given to remove the wires at any time on reasonable notice being given.

Bath.—When the Surveying Committee of the Town Council met last week, Mr. Sturges brought up a table which the Electric Lighting Committee had adopted, showing the hours at which the electric light would be switched on and off every evening and morning in the year. According to the table, the light would be switched on at 6.37 in the evening and off at 4.11 the next morning. It was decided to give a trial to the hours mentioned.

Yeadon.—The Yeadon Local Board have received a letter from Mr. R. Hammond, giving the terms on which he would prepare a scheme of electric lighting for Yeadon. The Board have decided to have another interview with Messrs. Andrews and Preece, of Bradford and Morecambe, and after that to call a public meeting for the purposes of asking the ratepayers' sanction to the Board undertaking the supply of electricity for both public and private lighting.

Electric Lighting at Wrexham.—On the 20th inst. a special meeting of the Town Council was held for the purpose of considering in committee a letter from Messrs. Lewis and Son, solicitors, stating that the Wrexham and District Electric Supply Company, Limited, were prepared, in accordance with the offer made by the chairman of the company to the Lighting Committee on April 25th, to sell to the Corporation the provisional order of the company for the sum of £500.

Meeting of Creditors.—A meeting of creditors of Selina Rowbottom, electrical engineer, of 82, Abbey street, Derby, carrying on business as S. Rowbottom and Co., has been held at Derby. The debtor's statement showed liabilities £302. 19s., of which £280. 4s. was expected to rank for dividend. The stock in trade, which cost £400, was estimated to realise £250, the machinery £36, trade fittings, etc., £25, furniture £20, and there were good book debts put down at £26. 10s. The alleged cause of failure was bad trade during the past year. The usual resolutions have been passed.

Lighting at Brighton.—As mentioned in our last issue, a considerable portion of the front—namely, from the western boundary to the Aquarium—has been lighted by electricity, the ceremony of switching on the current for the first time being performed by the Mayoress. The inaugural proceedings were very successful, and the electric light was seen to be a great improvement on the old system of lighting. Twenty out of the 40 lamps are put out nightly at 11 o'clock, the others being kept on till dawn. The difference in the cost as compared with gas is an annual increase of £300.

Weston-super-Mare.—At a meeting on the 11th inst. of the Inspection Committee of the Town Commissioners, Mr. Goode, of Messrs. Fowler and Co., of Leeds, waited on the committee to state that he would be willing to prepare and submit a scheme and estimate for fitting up an electric lighting station and laying down plant within the compulsory area. The committee explained that as the Board were now in negotiation with the Brush Electrical Engineering Company, Limited, they could not at the present time give his firm any instructions in the matter. The Commissioners are to hold a special meeting, when, among other matters, a letter from the Brush Electrical Engineering Company will be considered.

Halifax and Bermudas Cable Company.—The annual meeting was held at 33, Old Broad street last week. The report, which was adopted, stated that the year's working had resulted in a profit of £1,717, as compared with £1,261 for 1891-2. The balance of £1,682 brought forward made the sum to the credit of revenue £3,399. The net cable receipts were £4,856, as compared with £3,915. The loan of £9,000 from the Gresham Life Office at 6 per cent. has, since June 30th, been further reduced to £6,800, and the rate of interest to 5 per cent. The £10,153 which appeared in

the last balance-sheet as debit against capital account had been reduced to £6,754 by the application of the £3,399 to credit of revenue account. The fund for the redemption of the debentures is now £7,995 as compared with £5,175 last year.

New Installation.—On Monday night a numerous company assembled in the warerooms of Messrs. Robert Adams and Son, furnishing ironmongers, 14, East Maitland street, Edinburgh, for the purpose of seeing the electric light turned on in these premises. The work has been carried out under the superintendence of Mr. Mathew Buchan, electrical engineer, Portobello, and by an ingenious arrangement of lamps with coloured shades a most pleasing effect has been obtained. The engine is an Otto of 8.5 actual or brake horse-power, with two heavy flywheels. The dynamo is driven by one of the flywheels, a patent link leather belt specially adapted for such work being used. The dynamo, which is of special design, is constructed to light either arc or incandescent lamps, or of charging accumulators so that the lights may be turned on when the engine is not running.

Southampton.—When the Harbour Board met on the 19th inst. the Works Committee mentioned that an offer having been received from Messrs. Statter and Co. to supply some spare parts for electric cranes, at a cost of about £150, the offer was not entertained, though permission was given to the firm to make some tests as to the efficiency of these cranes, on the understanding that they would pay for the current supplied. Alderman Bone, in moving the adoption of the report, said that with regard to the electric cranes, an offer had been made by Messrs. Statter and Co. to supply some spare parts for the electric cranes at a cost of £150, but the committee felt there was no necessity for this, because they hoped to have the other crane working soon, and if anything happened to one the other could take its place until what was necessary had been done to it. The report was adopted.

Lighting at Dewsbury.—The Electric Lighting Committee of the Board of Guardians, after considering the tenders for lighting the workhouse, etc., have recommended the Board to formulate a specification based upon the several tenders, to provide for the lighting of the cottage homes, and to contain a clause guaranteeing the proper and effective lighting of the workhouse, etc., for a reasonable period thereafter, and that the tenderers submit tenders in accordance with such specification. Mr. Joseph Brown, at a meeting of the Board last week, said that the committee had gone very carefully into those matters, and had come to the conclusion that the cost of lighting the premises by electricity would be less than by gas. The minutes were passed, and it was resolved to apply for power to borrow £2,100 for the electric lighting of the premises. The Board have agreed that it be an instruction to the committee to prepare a specification for the complete lighting of the Board's premises, including the cottage homes.

Telegraphists' School of Science.—The eighteenth session of this school will be opened next week at the Central Telegraph Office, and the list of prizes gained by last year's students at the City and Guilds Institute and in the science and art examinations has been published. The names of the principal prizetakers are as follows: The City and Guilds Institute's Examinations: Telegraphy and Telephony: Honours grade, first prize in the United Kingdom, silver medal and £3, Mr. A. R. Nichols; first-class certificates, Mr. W. J. Bailey, Mr. A. J. Eames, Mr. A. R. Nichols, Mr. S. F. Pace, Mr. T. Pender, Mr. R. Nimmo, Mr. J. E. A. Sorrell, Mr. W. Stevenson, Mr. J. E. Taylor, and Mr. C. W. Wheeler. Ordinary grade: first prize in the United Kingdom, silver medal and £2, Mr. G. R. Adams; third prize in the United Kingdom, bronze medal and £1, Mr. C. G. Roach; first-class certificates, Mr. G. R. Adams, Mr. F. Barfield, Mr. A. J. Dawes, Mr. E. M. Draper, Mr. E. J. Eames, Mr. J. Kilford, Mr. H. Maguire, Mr. F. Morgan, Mr. C. G. Roach, Mr. T. Smerdon, Mr. C. J. Turner, Mr. E. W. J. Todd, and Mr. J. Wendon. The Science and Art Examinations—Magnetism and Electricity: Advanced stage, first class certificates, Mr. R. Nimmo, Mr. T. Pender, and Mr. J. E. A. Sorrell; second class certificates, Mr. G. R. Adams, Mr. A. R. Nichols, Mr. S. F. Pace, Mr. T. Smerdon, Mr. W. Stevenson, and Mr. C. W. Wheeler.

Huddersfield.—The rooms on the ground floor of the Technical School have been fitted up with the electric light by Messrs. Scott and Mountain, of Newcastle-on-Tyne, and last week the supply of electricity from the Corporation mains was formally turned on by Alderman J. F. Brigg, the president. Altogether about 125 incandescent lights have been distributed amongst the ground corridors and rooms, which comprise the weaving shed, the dyeing house, the chemical laboratories, and the chemistry, dyeing, and physical lecture rooms. These are departments of the school in which the improved light will be a great boon, proper colour being an important point in each. It is contemplated to extend the installation throughout the school. On the confirmation of the minutes of the Electric Lighting Committee of the County Council, Councillor Broadbent asked if anything had been done with regard to an exhibition of electricity. Councillor Marshall replied that if any manufacturer required to exhibit, and took a shop in the town, the committee would supply the light. The Central Wards Committee of the Town Council recommended, on the 20th inst., that St. George's square should be lit by electricity, and that four arc lamps should be erected. Alderman Brigg (chairman of the committee) said that no doubt if the experiment was successful the electric light would be more extensively used for the lighting of public thoroughfares. The recommendation was adopted.

Electric Lighting of Edinburgh.—A report on this subject has been presented by Prof. Kennedy to the Electric Lighting Committee of the Town Council. Pressure on our space compels us to postpone the publication of the report until next week. At a meeting of the Town Council on Tuesday, Mr. Mackenzie, at the request of the Lord Provost, made a statement as to the present position of the electric lighting question. On 16th May last, he said, the minutes were finally approved authorising the Corporation to proceed with an installation of the electric light. The matter was remitted to a sub-committee. It might appear to some present and to people outside that a great deal of time had been lost. Prof. Kennedy explained that a considerable amount of the preliminary work had to be rearranged in consequence of the decision of the Gas Commissioners not to supply gas for gas-engines at the rate for public lighting purposes, he having been in the belief that such a concession would be granted. In the circumstances, he had to begin over again, and this accounted for a considerable portion of the time that had elapsed. Recently, however, Prof. Kennedy had been instructed to prepare plans and specifications for the lighting of the compulsory area, and beyond that area, to the extent that he thought it would be judicious on the part of the Corporation to go. When these plans and specifications were ready, the committee would again approach the Council for their opinion as to going outside the compulsory area.

Electric Lighting at Lynton.—A correspondent writes that the electric light at Lynton and Lynmouth is not altogether a success. He states that during the winter months when the River Lyn is in full flood the electric light company have no difficulty in supplying a good current, but directly the river begins to get low the consumers of electricity suffer, showing that some additional power is required. For some time past it has been reported that the company intended using steam as an auxiliary when the water power failed, but up to the present time nothing has been done, despite the many complaints made by the consumers, and the utter impossibility to supply new customers (if they were forthcoming), after such experiences as have been witnessed during the past three years. Continuing, he says: If the present company do not care to incur the additional expense of extra machinery, perhaps the Local Board might be induced to consider the advisability of having the lighting of the two villages in their own hands, and eventually working it to the advantage of the ratepayers generally. Not only is a better light required, but complaints are numerous of the late hour when the current is put on, many householders having to use some other illuminant quite an hour before the electric light company think fit to lighten the darkness. The customers of the company will probably have something to say when the quarter's rent becomes due, but in a case like this, where individual complaints are not heeded, it would be well to remember that unanimity and determination may in the end do some good.

Electric Lighting of Derry.—The Corporation of Derry deserves credit for the business-like manner in which the scheme for the lighting of that city by electricity has been promoted and brought to its present position. The street lighting will be effected by arc lamps placed on the pillars that are being erected throughout the city. The system adopted by Mr. Blake, the consulting engineer to the Corporation, is continuous currents at high pressure, worked direct from the generating station. There will be two circuits in each street, and every alternate lamp will be placed on one of these circuits, so that one half of the lamps can be lighted or extinguished simultaneously. By a switch placed in the pillar each lamp can be extinguished separately. The city is divided into sections, east and west, and each section has its own distinct and separate circuits, dynamos, and machinery. All the city south-east of Shipquay-street and Bishop-street, including the waterside, will be supplied by its own distinct duplicate circuits from two of Siemens's constant-current dynamos, and all the city north-west of these streets will be supplied by different circuits from another pair of dynamos. A third set of dynamos is installed in the station as a stand-by. These six dynamos are each capable of running 60 arc lamps of 2,000 c.p., but as two of these will be held in reserve there will be in constant use four machines capable of running 240. The present contract is for the installation of 160 lamps. The arc lamps are of the Brockie-Pell type. The conductors are highly insulated copper cables, armoured, and laid directly in the ground. This extensive system of street lighting by electricity is being carried out by the Corporation without any additional tax on the ratepayers. It is estimated that the annual payment hitherto made to the gas company for street lighting will cover the repayments and interest of the loan of £15,000 granted by the Board of Works, and after the loan is paid off the cost of lighting the city by electricity will be only one-third of the cost of lighting it by gas. Everything is in a forward state. The generating station has been erected, the boilers are set, the machinery is in course of erection, and Messrs. Siemens Bros. and Co., Limited, are busily engaged in laying the underground cables and wiring the lamp pillars, and by end of next month it is expected that two of the circuits will be lighted and the other two circuits immediately after, so that the whole installation will be completed and working this winter. The Corporation is ready to undertake private lighting provided a sufficient number of ratepayers intimate their wish to be supplied.

Lighting at Killarney.—The Town Commissioners considered the question of public lighting at a meeting last week, Mr. J. Duckett occupying the chair. When the minutes of the last meeting were read, Mr. Moriarty stated that he attended through a notice served on him and on the town clerk by Mr. Leahy, cautioning him against drawing up any bond to be signed by Mr. Santry on the grounds that the resolution with regard to the gas tender was not put to the meeting, was not accepted, and that the meeting rejected the electric light tender, etc.; they did not at all consider the question of the gas tender. He came to have the instructions of the Board how he was to act in the matter. The

minutes showed that it was passed without a division, whatever that meant. Mr Haggard, solicitor, stated that the electric light company had put in a tender the last day for the lighting of the town, in pursuance of an advertisement. From what he heard he understood Mr M'Carthy urged there the last day that the tender did not state the names of the sureties proposed. As far as he could see from the advertisement, the latter did not require that at all. They (the electric light company) considered their tender was in proper order, as it should be in pursuance of the advertisement, and that being so, they asked to know, before the signing of the minutes of the last day, was the tender of the gas company accepted by resolution? They said it was not, and he was very glad it was not carried, because if it was they (the Commissioners) would have brought about this curious state of things in Killarney: that while the electric light company, in pursuance of an advertisement, tendered for a sum of £50, the Town Commissioners of Killarney, for the same light exactly as the gas, accepted the gas company's tender at the enormous sum of £92 10s. Now this was a very extraordinary state of things. He need not go back upon the history of the electric lighting question in the town. They might remark that when the electric light was first started, the Town Commissioners went so far themselves into the question that they applied to the Board of Trade for a provisional order to light the town with electricity, and now when the electric light was there, they gave the contract to the gas company at a far higher price. He understood they proposed to charge £2 10s. for each public lamp in the town, while the electric light company tendered for £2. He would ask them to postpone signing the minutes, if they were not strictly in accordance with the facts, and they did not appear to be. He could form no reason why the electric light company's tender was not accepted. He had heard that it was stated by Mr Leonard that the electric light company was a bogus company, and asked the Town Commissioners not to contract with any English company. He (Mr Haggard) knew a great deal about the electric light company, and certainly it was not a bogus company. The Commissioners themselves knew this when they were fighting the question before the Board of Trade. There was more Kerry money in it than in the gas company. It was a local company, and deserved local support. If they could supply light to the Town Commissioners cheaper than the gas company, they asked for fair play. If they could supply it at half the price, they demanded it as a right. If the Town Commissioners didn't wish to do so it would be a question upon which the ratepayers of Killarney might have an opinion to express, and he came there to say that their giving the contract to the gas company the last day was not carried at once. The clerk (Mr. M. Healy) stated that as regards the signing of the minutes that day the present chairman had nothing to say to them. The chairman who presided last day was responsible for them, and would sign them when he liked. The chairman last day was Mr T. T. O'Connor, who now declined to sign the minutes. After further discussion, on the motion of Mr Hurley, seconded by Mr. Brosnan, the following resolution was adopted: "Resolved, that we protest against the minutes, as they do not contain a resolution accepting the tender of the Killarney Gas Company, which was not put to the vote."

PROVISIONAL PATENTS, 1893.

September 18.

17501. **Improvements in and connected with alarum clocks, and electrical signalling appliances.** Walter Fielder, 57, Shakespeare road, Herne Hill, Surrey.

17521. **An improved method of illuminating by the electric arc.** James Jackson and Walter Dixon, 27, Sandyford place, Glasgow.

17526. **Improvements in or relating to fac-simile telegraphy.** Richard Joseph Crowley and Harry William Charles Cox, Harbour road, Queenstown, Ireland.

17557. **Improvements in electric motors.** Edmond Commelin, 6, Lord street, Liverpool.

17564. **Improvements in electric accumulators.** Adolf Koch, 23, Southampton buildings, Chancery-lane, London. (Complete specification.)

September 19.

17603. **Arc lamp.** Arthur Stanley Atwater, 52, Chancery-lane, London. (Complete specification.)

17605. **Improvements in dynamos and dynamo motors.** William Spiers Freeman, Invicta Works, Otford, Kent.

17618. **Improvements in electric motors.** Carl Erben and E. Bergmann, 6, Lord street, Liverpool.

17631. **Improvements in and connected with alarm clocks and electric sound signalling appliances.** Henry Newmarch, 166, Fleet street, London.

17645. **Improvements relating to the distribution and regulation of electric current.** Hubert Henry Grenfell and Octavius March, 45, Southampton-buildings, Chancery-lane, London.

17646. **Improvements in telephone switch operating mechanism.** Thomas Wood Ness, 46, Lincoln's-inn fields, London. (Complete specification.)

17658. ***Improvements in current conveyors for electric railways.*** *Reginald Walter Barker, Monument chambers, King William street, London. (The Lawrence Electric Company, United States.)* (Complete specification.)

September 20.

17666. **Lithophanique porcelain shades for the electric light.** William Isaiah George Lewis and Edgar James Bradley, 18, Chester street, Newcastle-on-Tyne.

17690. **In or relating to the transmission of electricity and sound along a conductor without a return circuit and a means of reducing electrical resistance in the air, earth, or sea.** Richard Joseph Crowley, Harbour row, Queenstown, Ireland.

17692. **An electric match.** Emile Coustau, 23, Plato road, Brixton, London.

17729. **An improved convertible combination lamp for electric light, gas, oil or candle fittings for general advertising.** Alexander Kelvie, 78, Adelaide road, Brockley, London.

September 22.

17796. **Improvements in electric arc lamp regulators.** Rankin Kennedy, 1, Clifton villas, Camden square, London.

17804. **Improvements in or connected with secondary batteries.** Francis Louis Berners and John Limbrey Higgs, 54, Fleet street, London.

17830. **A new and improved galvanic battery to be called a cartridge-shell battery.** George Abbott, 57, Pantiles, Tunbridge Wells. (James John Pearson, United States.)

17850. **Improvements in electrically propelled vehicles.** Ernest John Cotton and Alfred William Southey, 53, Chancery-lane, London.

17866. **An improved manufacture of electric accumulators.** Ludwig Wilhelm Schaller and George Ernst Wilhelm Scheffer, 45, Southampton buildings, Chancery-lane, London.

17867. **Improvements in apparatus for the electrolytical decomposition of brine and other liquids.** Herbert Guthrie and Malcolm Guthrie, 16, Lincoln's-inn fields, London.

September 23.

17874. **Improvements in globe holders for gas, oil, or electrical purposes.** Howard Walker, 12, Cherry-street, Birmingham.

17933. **Automatic supply fuse for electric supply currents, and in apparatus connected therewith.** James Hopwood, 11a, Cargill-road, Earlsfield, London.

SPECIFICATIONS PUBLISHED.

1892.

16315. **Electric telegraphs.** Bowen.

17093. **Electrostatic measuring instruments.** Ayrton and Mather.

18357. **Electrical switches.** Wyand and Schramm.

19184. **Electric lamps.** Imray. (Westinghouse Electric and Manufacturing Company.)

19404. **Cut-outs for electric generators, etc.** Raworth.

19821. **Current transformers.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

19834. **Telephonic apparatus.** Bennett.

20700. **Lighting trains by electricity.** Jones.

21243. **Electric light cables and lamps.** Webb and Thompson.

22038. **Incandescent electric lamps.** Cathrow.

23579. **Electric incandescent lamps.** Zobel and Buchmüller.

1893.

206. **Producing light by alternating electric currents.** Salomons and Pyke.

2331. **Secondary batteries.** Edgerton.

5987. **Telephone, etc., circuits.** Fletcher.

9262. **Electric meters.** Ericsson.

13066. **Electric incandescent lamps.** Boult. (Stoner.)

13858. **Galvanic element.** Heil.

13911. **Heating, etc., metals electrically.** Thompson. (Coffin.)

14076. **Electric measuring instruments.** Lake. (Armen.)

14474. **Telephone circuits.** Forbes.

NOTES.

Burmah.—A further extension of telegraphs is to be made in Upper Burmah.

New Arc Lamp.—A new arc lamp, termed "Progress," has been brought out in Paris.

Leeds.—The entire tramway system is expected shortly to pass into the hands of the Corporation.

Cambridge.—Lord Kelvin is to open the new science buildings at the Leys School on 28th inst.

Obituary.—The death occurred on Monday of Sir Stevenson Arthur Blackwood, secretary to the General Post Office.

Madras Tramways.—The plans for the construction of the electric tramways have been approved by the Government.

Pelican Club.—The National Telephone Company have taken over the old premises of the Pelican Club in Gerrard-street, Soho.

Telegraph to Gilgit.—The new line from Bundipur to Gilgit has been erected to within four miles of the highest part of the Burvil Pass.

Leicester Tramways.—The Town Council have instructed a committee to report on the subject of acquiring and working the tramways.

Railway Carriage Lighting.—Extensions in the lighting of the carriages of the Paris, Lyons, and Mediterranean Railway Company are in progress.

London-Paris Telephony.—No less than 150 words per minute can, it is said, be transmitted along this line in the French language, as compared with only 90 words per minute in English.

Rothwell.—A dispute between gas users and the gas company has led the former to dispense with gas for the present. This should lead to the question of electric lighting being considered.

Geneva.—An international electrical exhibition is spoken of in Geneva for 1896. This exhibition would be opened at the same time as the starting of the new municipal hydraulic and electric works.

Gilchrist Lectures.—The first of the Gilchrist lectures on science, in connection with the Bethnal Green Free Library, was delivered last week by Prof. V. B. Lewes on "The Atmosphere and its Relation to Life."

London School Board.—The new building of the London School Board on the Thames Embankment is lighted throughout by electricity, and the Council-chamber is ventilated by means of a fan driven by an electric motor in the central turret of the roof.

Birmingham Cars.—A suggestion having been made by a correspondent that the tramcars on the Bristol-road line should be operated on the overhead trolley system, other correspondents of Birmingham papers have written objecting to the system as being unsightly.

Telephony.—Telephone lines are being established between Leeds and Hull, London and Brighton, Swansea and Cardiff, Cardiff and Newport, Newcastle and Hexham, Newcastle and Morpeth, and Glasgow and Belfast. The entire system will consist of metallic circuits.

Military Telegraphy.—The War Department authorities have given instructions for telegraphic communication to be established between Sheerness Garrison and the new battery recently constructed at Barton's Point, which forms the outwork of the military defences for the protection of the entrances to the River Thames and Medway.

City of Manchester Tenders.—With regard to the advertisement printed on page iv. for the supply of electrical plant, the date for sending in tenders is 17th October, and the words "Town Hall, Manchester, 29th September," should read "Town Hall, Manchester, 5th October." This, then, makes the "17th inst." to be correct.

A Lady Electrician.—The first woman to receive the degree of electrical engineer was Miss Bertha Lampre, of Springfield, Ohio. She was "high man of her class" all through the course in the Ohio State University, and has proved herself practical as well as scientific by securing a position with the Westinghouse Electric Company at Pittsburg.

Union of German Electrical Engineers.—Dr. Slaby, of Berlin, presided at the first annual meeting of this society, held at Cologne last week. It was mentioned that no less than 762 persons had become members of the union, these including not only those engaged in the electrical industry, but also representatives of local authorities.

Train-Lighting.—In a note dealing with defective lighting of railway carriages the *Lancet* states: "Our protest is in the interest of the public and of the eyes of our patients, but the interest of the railways and the omnibus companies would also surely be served by the reform, and we strongly advise the public to patronise the company that is most generous in the matter of providing efficient light."

A Brilliant Meteor.—On Sunday evening a meteor of extraordinary brilliancy was seen at Leicester. It seemed to burst from near the zenith, and proceeded towards the western horizon, increasing very rapidly in brilliancy, until the ground and atmosphere were lit up as by an electric lamp of great power. Objects in the landscape could be clearly seen at a long distance for several seconds, and then the meteor disappeared.

Vulcanised Fibre.—A pamphlet has been issued by Messrs. Mosses and Mitchell, of Chiswell-street, London, E.C., concerning the patent vulcanised fibre supplied by the firm. Hard vulcanised fibre is largely used by makers of electrical instruments in place of vulcanite, ebonite, etc., and in dynamos for commutators, magnet heads, for switchboards, insulators, press buttons, etc. Tubes are likewise made of this material, as are also valves for air and circulating pumps.

Books Received.—"A Manual of Telephony," by W. H. Preece, F.R.S., and A. J. Stubbs; second edition, price 15s. "Electric Lighting and Power Distribution—Part II.," by W. P. Maycock, M.I.E.E., price 2s. 6d. "The Principles of Fitting," by a Foreman Patternmaker, price 3s. 6d. The above books have just been issued by Messrs. Whittaker and Co. "The Design of Alternate-Current Transformers," by R. W. Weekes, Whit.Sch., Assoc.M.Inst.C.E., price 2s., is just issued by Messrs. Biggs and Co.

Towing by Electricity.—Reference was made to this subject in a previous issue, and we now learn that an appropriation has been voted in New York State for carrying on experiments in towing on canals by means of electricity, and that the Superintendent of Public Works has arranged for some practical tests. Poles are to be erected on each side of the canal at Pittsford to suspend trolley wires which are to be strung over the middle of the waterway. The current will be collected in the ordinary manner.

Continuous from Alternating Currents.—Before the recent meeting of the Union of German Electrical Engineers, Mr. Pollak described an apparatus for converting alternating current to direct current, and for utilising the latter for charging accumulators. He claimed to obtain by the use of this apparatus an efficiency of 98 per cent., or a loss in conversion of only 2 per cent. He suggested that the adoption of this system would be advantageous for the working of electric tramways.

Telephony at Manchester.—The National Telephone Company is getting vexed with the Manchester Corporation with regard to underground wires. The company is anxious for the Town Council to come to a speedy decision on the subject, because it is alleged the work cannot be further delayed without danger of the dislocation of the telephone service. If facilities are not granted for placing the wires underground, the company threatens to duplicate the overhead wires. The cost to the company of reconstructing the system underground will be £40,000.

Morley Memorial College.—The honorary secretary of the Morley Memorial College for Working Men and Women, Waterloo-road, S.E., desires us to draw attention to new classes and lectures now commencing. A course of 10 lectures will be given on "The English Citizen" by Mr. Graham Wallas, M.A.; classes have been arranged in "Steam" and "Heat" in connection with the Science and Art Department, and in foreign languages, building and machine construction, political economy, etc. A prospectus can be obtained of the honorary secretary at above address.

An Electrical Fete.—As mentioned in our last issue, the Blackpool Town Council have decided to hold an "electrical *fête*" on the 18th inst. The arc lamps along the promenade will be lit for the first time, and it is proposed to festoon the whole length with incandescent lamps. The tower will be outlined from top to bottom with incandescent lamps surmounted by a group of arc lamps and a powerful search-light. There is to be a cyclists' parade, the machines to be lighted by electricity. There will also be a banquet, at which Lord Kelvin is announced to deliver an address.

Lightning Discloses a Mineral Spring.—During the prevalence recently of a thunderstorm in the neighbourhood of Seis, in the Tyrol, the lightning struck a heap of old wood which was piled on a rock, splitting the latter and setting fire to the former. When the flames had been extinguished, it was noticed that a stream of water flowed from amidst the rubbish. Further examination showed that the stream proceeded from the lightning-created cleft in the rock, and chemical analysis demonstrated that the water was impregnated with iron and magnesium, in the form of sulphates.

Willans Memorial Fund.—We are asked to mention that the subscription lists for this fund will be closed on November 1, so that any engineers or others who intend to send in subscriptions and have not done so should do so at once. Mr. Alexander Siemens, 12, Queen Anne's-gate, Westminster, is the treasurer of the committee. It may be remembered that the proposal is to establish a fund in connection with the Institution of Mechanical and Electrical Engineers from the interest of which a premium might be awarded for papers relating to the subjects which the late Mr. Willans made so peculiarly his own.

Water Power in India.—The committee of experts appointed to enquire into the question of utilising the water power shortly to be available at Peniyar have sent in a report to the Secretary of State. There is believed to be no doubt as to the practicability of turning this water power to good account. It is submitted that the first step that should be taken is the construction of a light electric railway from the foot of the hills where the power is to be obtained, to some convenient spot on the existing railway system of Southern India. By this means the current could be distributed for the lighting of towns, etc.

University College, London.—The new engineering and electrical laboratories in this college are now ready for the reception of students. This new wing of the college will afford greatly increased facilities for teaching mechanical, civil, and electrical engineering. Complete laboratory and lecture courses in these subjects are given under the direction of Prof. T. Hudson Beare, Prof. J. A. Fleming, and Prof. L. F. Vernon-Harcourt. In addition to these engineering laboratories, new physical laboratories have been erected for Prof. G. Carey Foster, and the whole of the new buildings are completed for the session which is now commencing.

Hardening Aluminium.—The hardness which aluminium is said to lack can, according to a new process, be imparted to it by the addition of chromium. Of course certain precautions have to be taken to alloy the two metals, owing to the difference in their fusing points. If electrolysis is employed for this purpose, one or another of the known methods can be used, and the alumina, salts of alumina, cryolite, etc., treated direct with a determined quantity of granulated chromium or chromium in any other suitable condition, or with the salts or oxides of chromium. Finally, an ingot of chrome-aluminium is obtained, which can subsequently be treated and transformed by known methods. This method, it is believed, renders the aluminium as hard as chrome-steel.

Primary Battery.—A primary battery has been devised by Mr. H. C. W. Emery, in which the cells are formed in the shape of a ship's rudder, the elements being suspended vertically from the mouth, which is of small area as compared with the lower part of the cell. The elements consist of zincs and carbons, and when the battery is in its normal position, they are immersed in the electrolyte, which is a solution of chromic acid. In this position the battery is in working order, but when it is required to stop its action it is laid on its front, the cells and the elements thus assuming a horizontal position. The quantity of the depolarising solution is so regulated that when in this position the elements are high and dry above the solution, which lies in the enlarged part of the cells, and the generation of the current ceases.

Honours.—The American Electro-therapeutic Association, having widened its constitution so as to admit electrical experts, has just elected as fellows the following gentlemen: A. E. Kennelly, chief electrician of the Edison Laboratory, N.J.; J. J. Carty, vice-president N.Y. Electric Society; Prof. E. J. Houston, Philadelphia; H. Newman Laurence, M.I.E.E., London, Eng.; and Mr. J. Jenks, electrical engineer, N.Y. As this association is a select body of medical men, many of whom stand high in their profession, the admission as fellows of electrical experts who are not medical men is a significant step in scientific co-operation. We note with pleasure that Mr. Newman Laurence is among those thus honoured, and that so important a body has recognised the thoroughness and honesty of his work in matters relating to electricity and the human body.

Not Idle Tales.—Prof. Oliver Lodge, in the course of his inaugural address on "The Advantages of Indirection," delivered on the 29th ult. on the occasion of the annual distribution of prizes at the Liverpool School of Science, Technology, and Art, said it was true that all could not be leaders, "but unless a youth is ambitious he will achieve nothing. There is plenty of room to spread yourself: make

yourself a good base or you will never build high. You are going to aim high: by all means do so, but don't erect a slender top-heavy column on the surface. The higher you intend to build the broader and deeper must you lay your foundations. You who wish to become skilled artisans, do not imagine that heat, light and sound, magnetism and electricity, chemistry and mechanics, are idle tales. If you have a chance of learning these things, learn them; you can hardly overestimate the value of an acquaintance with scientific principles."

An Electric Tug-of-War.—The anniversary of the opening of the Manchester and Liverpool Railway—which took place, it will be remembered, on September 15, 1830—was celebrated by the railroad interests of America (no unimportant section of the industrial world) in the shape of a "railroad day" at the Chicago World's Fair. A great number of railway men, both Americans and foreigners, assembled together, and were treated to some addresses from prominent railroaders on topics of common interest; subsequently proceeding to an inspection of the railway and kindred exhibits in the Transportation Building. One special feature of the day's proceedings which caused particular interest to the onlookers was a tug-of-war between a steam locomotive employed for shunting purposes on the Baltimore and Ohio Railroad, and the electric locomotive exhibited by the General Electric Company, some details of which, accompanied by illustrations, were recently given in our pages (see the *Electrical Engineer*, July 28, 1893). The result of the tug was a defeat for the electric locomotive.

Chicago Exhibition.—In the course of a lengthy article in the *Times* of yesterday, a correspondent at Chicago says in regard to the Machinery Building: "The American tariff interferes with the sale of machinery, electrical supplies, and the transportation display, but manufacturers have generously exhibited in spite of this obstacle, and they generally announce the sale of patent rights for America. There are three lines of shafting in the machinery section, one being driven by a 350-h.p. horizontal compound Galloway engine. The other two lines are driven by two Willans and Robinson single-acting central-valve engines, respectively of 360 h.p. and 165 h.p." The same correspondent states that there is not much British competition in the Electricity Building, only five exhibitors appearing in this enormous display. The British Government makes an extensive postal-telegraphic display, which is one of the best exhibits in the building; the General Electric Company, of London, shows electrical apparatus and arrangements for lighting; the Epstein Electric Accumulator Company shows batteries, etc.; and J. G. Lorrain has various electrical appliances.

Cables, Wires, and Batteries.—A revised price list of electric light cables and wires has been issued by the India Rubber, Gutta Percha, and Telegraph Works Company, Limited. The list is divided into two parts; the first referring to vulcanised and the second to non-vulcanised rubber cables. In the first part three series of cables have been arranged suitable for installation wiring where the E.M.F. used is only moderate. Then come cables for underground work and the concentric series, made for pressures up to 2,500 volts. During the process of manufacture all the vulcanised cables, wires, etc., are subjected to a temperature considerably over 200deg. F., and they can therefore be relied upon to work efficiently even at such high temperature. They are, moreover, tested in water with a battery giving an E.M.F. of at least 500 volts, and the tests for insulation taken after one minute's electrification, and after they have been immersed at 60deg. F. for at least 24 hours. This high pressure and long immersion are calculated to break down any faults that might exist in the cables. The same company have issued a list of the Silvertown dynamos, made in sizes giving outputs of from 1,500 to 48,000 watts, and a list of galvanic batteries for telegraphic, signalling, and electric bell work, for testing purposes and for torpedo firing and for blasting operations.

Currents between Gas and Water Pipes.—Some time ago attention was drawn in the *Genie Civil* to the difference of potential between gas and water pipes, and now Dr. S. Kalischer, in the *Elektrotechnische Zeitschrift* of the 22nd September, refers to experiments made in this direction in the physical-room of the Agricultural High School. The object of the investigations was to determine whether in the path of the current any relation was found to the magnetism of the earth and to meteorological data. No less than 2,000 observations were made by Dr. Kalischer in conjunction with Dr. Less. The inconstancy of the current rendered the making of the measurements very difficult, but Dr. Kalischer was enabled to make a number of measurements of the E.M.F. on the compensation method. A Daniell cell was used as the compensating element, and the ascertained maximum current obtained with this cell amounted to ·0024 ampere, and the minimum to 0·0004 ampere. The greatest internal resistance of the "earth battery," as the combination of the pipes with the earth is termed by the author, came to ·5871 ohm and the smallest to ·0310 ohm. As far as the direction of the current is concerned, the water-pipe plays the part of zinc in a galvanic cell: the current passes from the water-main through the earth to the gas-main. A permanent diminution or increase in the current was not noticed. The author concludes by stating that it will perhaps be possible to ascertain further information concerning the nature of these currents by the use of registering apparatus.

Electric Distribution of Time.—Mons. H. Campiche, of Geneva, who supplies all the clocks for the Egyptian Government railways, post office, and telegraph departments, has devised an extremely simple type of electric regulator or master clock, from which may be operated a number of dials throughout a circuit for the purpose of showing time synchronously with the regulator. The appliance consists mainly of a seconds pendulum, near the top of which is fixed a horizontal spring actuating a ratchet wheel with 30 teeth. The wheel thus makes one revolution per minute: on its axis a lever is carried, with a contact at the end. As the wheel revolves, an electrical contact is thus made once in each minute, the current passing momentarily through the entire circuit, and operating all the receiver mechanisms with ordinary electromagnet and ratchet devices. There is also inserted in the circuit an electromagnet fixed to the pendulum case, with a balanced pivoted armature. The latter is raised at every vibration of the pendulum by an arm fixed to the latter through the intervention of a spring; at the moment when contact is made and current passed through the circuit, this electromagnet is, of course, energised similarly to all those in the receiver mechanisms, the armature is attracted downwards so as to give a blow to the pendulum arm and thus keep up the oscillation. The force of this blow is regulated and kept in form by means of the spring between the arm and the pendulum itself. Every minute, therefore, a fresh impulse is given to the pendulum, and the winding up of a clock train wholly avoided. A few Leclanché cells of No. 2 size are sufficient to supply the necessary power for operating the magnets.

Electrical Engineering in Queensland.—A correspondent informs us that the central station of the Rockhampton Gas and Coke Company, Limited, which

is the only gas company in Queensland that supplies both electric light and gas, was erected under an Act granted in November, 1889. The plant at the station, which was started in September of last year, consists of two 120-h.p. Roots boilers by Conrad Knap and Co., Lincoln; a 100-h p. indicated horizontal engine, by Davey, Paxman, and Co.; and a 6½in. by 6in. Westinghouse engine, a 280-ampere 110-volt Hookham patent dynamo with constant-lead brush gear, hand-regulated by resistance in field-magnet circuit, and an A. Mordey-Victoria alternator, the whole plant being thus capable at present of supplying 2,000 8-c.p. lamps, of which 914 are in use outside the works and 1,700 on order. The Fitzroy Bridge is lighted by alternate-current arcs, and the cathedral by eight arcs and 20 incandescents. The whole of the mains are laid underground on the Callender system, and the current is charged by meter or by contract as the case demands. Hookham's meters are used. The supply is from 4 p.m. to 7 a.m., and is maintained well. The company are also undertakers of isolated installations, their largest at the present time being the re-establishment of the electric light plant at the Mount Morgan Gold Mining Company's Works, Mount Morgan. This new plant consists of 60 light and 25-light 10-ampere Kapp dynamos, with Brockie-Pell arc lamps in series, and a Crompton 100-light incandescent dynamo. The circuits are over eight miles in length, and are carried overhead on poles and Pell's patent fluid insulators. The engine is a 20in. coupled high-pressure, by Fowler, of Leeds. There are two Paxman Lancashire boilers. Over 50 arcs and 30 series Bernstein lamps are in use on the high-tension circuits, and 85 incandescents of 16 c.p. on the low-tension. These two installations are the largest in Queensland, and have been entirely planned out and erected under the immediate superintendence of Mr. A. E. Neal, the electrical engineer to the gas and coke company.

Maximum Efficiency of Arc Lamps with Constant Watts.—In a paper on this subject presented to the recent Electrical Congress in Chicago, Prof. H. S. Carhart, of Ann., stated that it was of interest to determine, in connection with the proposal to define a 2,000-c.p. arc light in terms of the watts expended on it, whether the illumination is independent of the current as a variable. He said that if a 2,000-c.p. lamp shall be defined as one requiring 450 watts for its maintenance, shall the current be 10 amperes and the potential difference of the arc 45 volts, or will a smaller current and a higher voltage give higher illumination? The experiments to which the author referred were conducted by three of his pupils, and they were confined to the circuit of a constant-current dynamo with closed-coil armature, and to soft plain carbons $\frac{7}{16}$in. diameter. The method employed was as follows: With any constant current within limits a series of measurements of candle-power was made by changing the length of the arc, and hence its potential difference. A curve was then plotted with candle-power and volts as co-ordinates. Fifteen such curves were drawn for currents ranging between 6·75 and 10·75 amperes. Then any number of watts was chosen, say 450, and this was divided in succession by the several currents used in obtaining data for the 15 curves, or by so many of them as came within practical limits. With the potential differences obtained in this manner, and the corresponding candle-powers read off from the several curves, another curve was constructed, with candle-power and volts as co-ordinates, and with the watts constant. Such curves showed a maximum point corresponding to the volts at which the lamp gives the greatest candle-power. The measurements were all made in the photometric room with a 32-c.p incandescent lamp as a standard of comparison. The author had plotted only four of the 15 curves composing the series. In the four cases, with currents of 7·3, 7·9, 8·7, and 10·75 amperes respectively, a maximum of only a little over 1,100 candles was obtained. Two curves derived from all the data, and with constants of 450 and 500 watts respectively, both showed a pretty well defined maximum at 54 and 55 volts respectively. Hence for a lamp of 450 watts the current should be about 8·4 amperes with the above-mentioned carbons. The candle-power was then 900. At 10 amperes and 45 volts the curve showed the surprising fact that the candle-power was only 450. With 500 watts the current rises to about nine amperes and the voltage to 55. The author does not attach great importance to these particular figures, but the series of experiments shows a very large variation of candle-power, current and potential difference varying inversely, their product or the watts remaining constant.

A Powerful Lighthouse Light.—What is regarded as the most powerful lighthouse light in the world is now being fitted up at the Cap de la Hève lighthouse. The old Alliance magnetos have been replaced by two direct-current dynamos, giving from 25 to 100 amperes at 70 volts, and two de Méritens alternating magnetos, yielding the same intensity at from 40 to 45 volts. The current will be used in Serrin regulating lamps having cylindrical carbons. The optical apparatus devised by M. Bourdelles in place of the old fixed lights, produces a flashing light every five seconds. It possesses this peculiarity over the old type of apparatus—namely, that the number of lenticular panels, which in lights of the first order varies from eight to sixteen, has been reduced to four. The difficulty of revolving the panels at the necessary rapidity so as to produce the flashes at sufficiently regular intervals has hitherto prevented this improvement being carried out, but this disadvantage has now been overcome in a most ingenious manner. A float placed in a mercury bath supports the optical panels, the weight of which is considerable, and which is equilibrated by the "push" of the liquid. The resistance to be overcome in the rotary movement is thus reduced to the friction on the mercury. By means of this arrangement, the new light at the Cap de la Hève will be able to make a complete revolution every 20 seconds, whereas with the ordinary lighthouses of the first order at least four minutes are required to effect this operation. The new apparatus has been constructed by Messrs. Sautter-Harlé and Co., and the optical part is made of a special glass composition from the works of Saint-Gobain. The old square lantern has been removed and a circular one substituted. The following table, giving the luminous powers and the range of the light in fine weather for the different systems used at la Hève, shows the great progress made:

Apparatus.	C.P.	Distance visible in nautical miles.
Oil lamps with reflectors	7,600	41
Oil lamps with fixed lenticular apparatus	19,000	49½
Electric arc lights with fixed lenticular apparatus	25,000	57½
Electric arc lights with flashing lenticular apparatus	24,000,000	130½

The most recent electric lighthouses—Ouessant, Belle-Isle and Barfleur—have a power of 5,700,000 candles, and are visible a distance of 62 miles. The new lighthouse light at the Cap de la Hève will, however, be more powerful, attaining something like 30,000,000 c.p. to 40,000,000 c.p., and its geographical range is about 23 miles.

Lighting of the Gardening and Forestry Exhibition.—The method of lighting this exhibition, now being held at Earl's Court, S.W., is of a most varied character. It comprises high tension series arc lighting, low tension parallel arc lighting, alternate current arc lighting with transformers, high-tension alternate-current incandescent lighting with transformers, direct-current electric motors, and alternate-current electric motors. The steam plant consists of four Davey-Paxman steel loco. boilers working at a pressure of 120lb., a compound horizontal fixed engine of 210 i.h.p., one of 120 i.h.p., and a coupled compound engine of the girder type capable of working up to 120 i.h.p. These, which are also by the same makers, are arranged to drive respectively on to three independent countershafts working in line with couplings ready for connection in event of any one engine being stopped. The dynamos are driven by means of belts from this line of countershafting. The dynamos comprise eight Brush arc light machines, each capable of running 35 10-ampere lamps in series, two of which are reserve, two low-pressure direct current Victoria dynamos used for the large projector arc lamps in the arena section, one 100-kilowatt Mordey alternator, and one 37-kilowatt Mordey alternator. The larger of the two alternators, working at 2,000 volts, maintains 1,000 incandescent lamps throughout the buildings and grounds and the arc lamp for the luminous fountain, these all being worked in groups from small transformer sub-stations. The 37-kilowatt alternator supplies the current for the lighthouse only. In addition to the above plant, a complete set of gas-engine, dynamo, and accumulators is in operation to maintain a continuous light for an experiment in plant culture under electric light, daylight being completely excluded, and the accumulators supplying the light during the night. There are 210 Brockie-Pell arc lamps arranged throughout the building and grounds. An interesting feature of the outdoor lighting is a small illuminated fountain in the Western Gardens. This has been specially designed by Mr. G. C. Fricker, who has carried out the lighting at the exhibition. It is a new departure in colour-changing fountains, being perfectly automatic in action and working most successfully. The light from a powerful arc is thrown horizontally from some 15 yards distance in parallel coloured beams on to a mirror at 45deg., from which it is reflected vertically through a glass plate under the jet. There are five distinct colours which succeed each other at an interval of one minute by means of a simple relay and electromagnetic gear. The effect is pretty, and it is probable that the next application of this device will be on a considerably larger scale. The lighthouse in the Central Gardens carries one of the most powerful arcs which have ever been used. The current supplied is 250 amperes, and the light is refracted by a powerful set of revolving lenses into 12 separate beams, each of which, as it slowly sweeps the horizon, can be seen in dazzling brilliancy for some miles around London. The lighting of Captain Boyton's World's Water Show constitutes a large section of the installation. There are on the roof around the arena 10 projector lamps, each of about 10,000 c.p to 15,000 c.p., and three search lamps of some 20,000 c.p. to 30,000 c.p. each. In addition to these there are 20 arc lamps of 2,000 c.p., and about 100 incandescent lamps scattered over the ground. As a mark of the appreciation in which Mr. Fricker's services have been held, a special honorary medal has been awarded to him for the electric lighting of the exhibition.

Refuse Destructors.—A paper on "The Disposal of Refuse" was read by Mr. Wm. Warner, A.M.I.C.E., before the British Association. The author gave some figures concerning the amount of refuse dealt with per cell in different towns and the horse-power obtained from the destructors. As the subject is of considerable importance, we produce the author's statements as follow: "From a report of the committee at Oldham, Horsfall's destructor deals with 5·5 tons per cell, and at Leeds, with Horsfall's steam-jets and Hewson's improvements, their destructor deals with 5·5 tons per cell in 24 hours. The cost of burning refuse at these towns, exclusive of interest on capital, is: Batley, 7½d. per ton; Blackburn, 10d.; Bradford, 11¾d.; in Fryer's destructors, 9¾d. per ton, the cost at Hornsey is 9d.; and at Newcastle, 8d., or equal to 8½d. per ton in Warner's Perfectus destructor. At Oldham the cost is given at 1s. 1d. per ton in Horsfall's destructor. The horse-power given at Batley is 5, at Blackburn 5 6, Bury 4, Bradford and Leeds about 4 per cell, which is equal to about 4·5 h.p. generated from 5cwt of refuse, or about 125lb. per horse power, and 6·25lb. to 1lb. of water evaporated, giving a comparison of about one forty-second the value of coal when burnt in Fryer's destructor at the above towns. The horse power at Hornsey is about the same in the "Perfectus" destructor. At Oldham the horse-power is given at 50 for six cells, equal to 8 3 per cell, or about 46lb. of refuse per horse-power, and 2·3lb. to 1lb. of water. It is, however, difficult to reconcile these figures, as practically the same furnaces, with equal steam generating appliances, give less than half that power at Leeds and Bradford. It will be seen from these figures we cannot look forward to a large amount of power for electric lighting, and it is even questionable whether the power generated could be usefully adopted for that purpose. Take a town like Nottingham, and suppose its refuse to have the average steam-producing qualities, we should get about 300 h p. for an expenditure in labour of nearly £17 per day, equal to over £5,000 per annum. With coal, the cost for labour would be only £150 per annum, and the cost of coal for fuel would be under £1,500; therefore, taking the refuse to cost nothing for delivery at a destructor works conveniently situated for producing electricity, the actual loss would amount to no less than £3,350 per annum over coal fuel, and if we take into consideration the cost for repairs and interest on capital, this loss would be greatly increased. Looking these facts in the face, electric light produced by burning refuse can only show economical results in very exceptional cases, and authorities should well weigh the matter over before launching into a scheme of that kind. I have estimated the cost of burning at 10d per ton, but if the treament should cost 1s., the increased loss would be £1,245 per annum, making a total loss of £4,590 per annum. Taking the comparison of burning refuse in different kinds of destructors, these figures should be taken carefully into consideration, as 1d. per ton more in the cost of burning means over £600 per annum at a town the size of Nottingham. I have dealt with the burning of refuse from a financial point of view, and now will review them as a sanitary improvement. On reference to the cost at various towns per ton of refuse burnt, Blackburn is 2¾d. per ton; Bradford, 5d.; Burslem, nothing; Ealing, 3¾d; Eastbourne, 1½d.; Hampstead, nothing: Liverpool, 2½d.; Longton, nothing. showing an average of 1¾d. per ton. It will be seen that the cost of treatment is considerably increased, and where steam power is not used, this will tell against the working expenses; but where the power is useful either for electric light, sewage pumping, or other purposes, the amount spent in coke is returned in useful work, and therefore the apparatus does two things—i.e., it pays its own expenses for fuel in the form of steam, and at the same time destroys the offensive gases produced in the destruction of house refuse."

TRANSMISSION OF POWER.*

BY R. S. ALLAN.

The transmission of power is a subject of the utmost importance to the engineer, as I may say his reputation chiefly depends upon the results obtained by his mechanical contrivances. In these days when competition between manufacturers is so keen, and the prices accordingly so much cut down, economical machinery is essential, so that it becomes the chief aim of the engineer to design his motors and transporters with the greatest possible working efficiency. The transmission of power may conveniently be divided into two primary classes—viz. :

1. Short-distance transmission.
2. Long-distance transmission.

Various methods are adopted in each case as are thought most efficient and economical under the working conditions.

Short-Distance Transmission may be obtained by the following means : (1) Direct driving from motor shaft ; (2) friction gearing ; (3) toothed gearing ; (4) screw gearing. Direct driving consists in prolonging the main shaft of motor, and obtaining the necessary power from it without the use of countershafting or gearing. The most common adoption of this method is in the marine engine, where the power transmitted is sometimes enormous, the most notable examples being the twin Cunarders "Campania" and "Lucania," each of whose shafts will transmit no less than 15,000 i.h.p. when running at about 80 revolutions per minute. Such a shaft would be about 24in. in diameter.

Friction Gearing is those forms in which the power is transmitted solely by the adhesion or reluctance of the driving agent to slip. The various devices in use at the present day are belting, ropes, and friction wheels. Driving by belting consists in straining flat belts, or bands, over cylindrical pulleys, or drums, which are keyed on the shafts to be actuated. Various substances are used for belting, such as leather, waterproofed cotton, rubber, and canvas, woven hair, etc., according to the class of machinery under operation. Leather is the substance most frequently used, and when properly tanned and stretched is the most durable, especially when running between setters for intermittent motion, as in workshops ; the edges of belts made from other materials fraying much sooner under this action. Leather is generally used as a flat belt of varying width and thickness, according to the power required, and to prevent slipping off runs on a slightly rounded pulley. Messrs. Tullis, of Glasgow, have introduced what is known as the chain belt, consisting of short links of leather connected in rows by wire pins passing through each series. This belt is very flexible, easily shortened, and the makers claim that when it is concaved to suit the convexity of the pulley it can transmit 25 per cent. more power than an ordinary flat belt of the same width. I think that this belt would be specially suited for high speeds, as the air current generated and drawn in by centrifugal force between the belt and pulley would readily escape between the links. This centrifugal action can be counteracted with ordinary belting by boring holes at short intervals, but this of course is at the strength of the belt. Messrs. Tullis have also introduced the narrow belts with V projections riveted on the lower side, and working under the same conditions as ropes to be described further on. Leather belts have been made up to 75in. in width, Messrs. Sampson, of Manchester, having recently placed a belt of this width to transmit about 700 i.h.p. for a woollen manufacturing firm near Brussels. The composition belts are preferable to leather under some circumstances, as, *e.g.*, in damp places waterproofed cotton or vulcanised indiarubber would be employed. Cotton has a breaking strength of about 4,500lb. per square inch of section, while leather and rubber give way at about 3,000lb., but the working tension is usually far below this, or from 300lb. to 650lb. per square inch of section.

Friction Wheels are sometimes used where a quick disconnection is desired, and where the power to be transmitted is small and no great uniformity required. The wheels are generally of the plain cylinder or wedge types. In the former, the working surfaces may be iron, but a coating of wood or leather greatly increases the adhesion. In the latter type, the working surfaces are V grooves with an angle of about 30deg., turned true from solid cast. This style lessens the wear by increasing the working surfaces.

Rope Gearing.—This form of drive is now becoming extensively used in place of leather belting, especially for main drives. The ropes are made of hemp or cotton, the latter material being the most economical. They are circular in section, consisting of three or four strands sometimes twisted round a soft central core, thus giving the rope flexibility and preventing undue hardness. The main drive with rope gearing is taken from a large pulley keyed on the shaft, and having V-grooves truly turned on its circumference. The grooves have their sides inclined to include 45deg., and are shaped so that the ropes do not bottom, but are wedged in, the adhesive force being chiefly derived from the weight of the ropes themselves. The breaking strength of hemp varies from 9,000lb. to 12,000lb. per square inch of section, while cotton is about half of this. The power transmitted depends on the speed and tension, which are generally about 200lb. to 350lb. for cotton, and up to 900lb. per square inch for hemp, with a velocity of from three to six thousand feet per minute. The size of ropes in practice range up to 2½in. in diameter. Each rope requires a groove for itself, and as many as 70 ropes have been run from one pulley, transmitting about 4,000 h.p. Several drives at different elevations would be taken from such a pulley ; and several ropes used for each drive. In addition to hemp and cotton, ropes made of leather, of square and spirally twisted sections, are sometimes used for light transmissions, the groove for the former being shaped about 70deg. Some makers profess to cast the grooves smooth enough for working, but they cannot be too smooth, and are better turned, those sizes below ¾in. being generally cut from the solid cast. For the smaller sizes of pulleys the grooves when cast in may be made tolerably smooth by means of a rapidly-revolving emery disc introduced into groove as it slowly revolves in the lathe.

Toothed Gearing.—When the power to be transmitted is large, and where a constant or relative speed is required, friction rollers would slip, and to overcome this defect projections are cast on the face of the driving wheel working into interstices on the follower ; and this constitutes what is termed toothed gearing. The form of this projection or tooth, as it is called, should be such as to give the same uniform smooth motion as with plain rollers. The curves which are found to fulfil these conditions best are the involute and the epicycloid, and in practice these have been adopted. The involute is most suitable for some classes of machinery in which the pitch circles of the gear do not always coincide, as in crushing and rolling plant ; but the epicycloid is almost universally adopted in general engineering. The exact contour or curves of the tooth is obtained by rolling a circle, the diameter of which is generally from one and a half to three times the pitch on the pitch circle of wheel or pinion. This gives an epicycloidal curve for the point of the tooth, and a hypocycloidal for the flank, when the wheel and pinion work externally, but when internally the curves of the wheel are reversed, the hypocycloidal becoming the point, and the epicycloidal the flank. The rolling-circle method has the disadvantage that only a wheel and pinion specially made for each other will work together. This objection can be overcome by using the odontograph invented by Willis, when all teeth, if of the same pitch, will work harmoniously. The teeth of gear wheels when first introduced were cut by hand ; later on this gave place to casting from a full-sized pattern. These wooden patterns, owing to shrinkage induced by repeated contact with the damp mould, sometimes become distorted, and uneven teeth is the result, gear so produced tending to knock. A marked improvement on this method was the introduction of the moulding machine, which by gear wheels can divide the wheel circle into the exact number of parts there are teeth. For this method

* This paper is the prize essay of the Aberdeen Mechanical Society. The length of essay was restricted to what could be read in 15 minutes.

only the pattern for one tooth and a core-box for one arm is required, or, better still, a set of arms if a suitable pattern can be found among the stock. All teeth moulded from the above methods, however, require a good amount of clearance, which is very objectionable and detrimental to gearing liable to sudden shocks. Modern science and improvement, however, has resulted in the wheel rim being cast solid, and teeth cut by milling tools turned to the exact shape of tooth section. Teeth made in this way are very accurate, and to all appearance approach as near as possible to perfection. They can be run at a high speed, and having no clearance are strong, and the whole face is ensured of contact, thus distributing the driving force: and these are results and advantages which cannot be obtained with any great degree of accuracy in moulded teeth. The various forms of wheels are spur, bevel, mortice, and helical. Spur wheels are used to connect two shafts running parallel. Bevels are the frusta of cones, the apices of which would meet in the intersection of the shaft centre lines. When of the same size they are called "mitre wheels." Bevels generally run at right angle, but when at any other they are called "skew bevels." Mortice or cog wheels are employed when the machinery is liable to shock, and where a quick smooth motion is desired. They consist of wooden teeth, generally of hornbeam or beech, driven into rectangular holes cored in wheel rim, and are fixed at the back by iron pins and wooden wedges. Helical wheels have their teeth inclined generally at 55deg. across the face of rim. The teeth are just part of a screw generated on surface of rim, and they may either be single or double helical. The former is sometimes objectionable on account of end thrust, but this defect is entirely overcome by the double helical which, when cast with all their teeth intersecting in the centre line plane, give a very steady motion each side of the tooth supporting the other. Helical is the strongest form of tooth we have, being about 20 per cent. stronger than the ordinary spur, while mortice is about 25 per cent. weaker. Other forms of toothed gearing are in use, such as sprocket and pocket wheels. Sprocket wheels and chains are used where a relative speed is required at a distance too great for wheel contact. The teeth are set radially on the rim of wheel, and work into pitched chains, which are now made up to large sizes. The links in the larger sizes are made of cast steel or malleable cast iron, while the smaller sizes are made from mild steel These chains are largely used in elevating and conveying machinery, as the links form a ready means of attaching buckets and pushboards. Pocket wheels are generally made to suit the common forms of linked chains, the spaces for the links being hollowed out on the wheel rim, giving the name pocket. This style is chiefly used in hoisting machinery.

Screw Gearing is only used for secondary motions, such as in machine tools, etc. The screw threads usually employed for this purpose are either square or buttress, and work in conjunction with their nuts, transmitting the power by end pressure. The best example of the screw is for propelling steamships, the nut in this case being the fluid water. The endless screw and worm is another application, and, although most wasteful of power, is found very convenient in cases where the driving is wanted non reciprocal, as when the inclination of the thread exceeds a certain amount the worm alone can act as the driving agent. The best example of these devices that I know of in Aberdeen is at the shearpoles, where the worm and wheel are used for the hoisting motion, the screw and nut for the derricking.

Long-Distance Transmission is now chiefly employed in connection with the centralisation of power—*i.e.*, in places where a great amount of power is required spread over a large area. It is found better to generate the power at a central station, and transmit it in quantities to suit the consumers, thus obviating the necessity of each small consumer having a generating plant of his own. The methods in use at the present time are: (1) Water under pressure. (2) Wire ropes. (3) Compressed air. (4) Electricity.

Water Under Pressure.—When water can be stored at a high level it possesses latent power by virtue of its weight, this potential energy being proportional to its height. This method was first introduced by Armstrong on the quays at Newcastle, where the head was obtained by pumping the water into tanks high enough to give the working pressure. When higher pressures came into use the height of those tanks became inconveniently great, and this led to Armstrong bringing out his hydraulic accumulator, the adoption of which marked a new era in hydraulic transmission, and to which this system owes its success. The hydraulic accumulator is the opposite of the hydraulic press, and consists of a cast steel or iron cylinder fitted with a ram kept tight by leather packing, and loaded to give the requisite pressure per square inch. A steam-engine is employed to pump the water into the cylinder against this weight, the ram rising as the quantity of water increases. The rise and fall of the accumulator are automatically regulated by tappet arrangements connected either to the engine throttle or to a relief valve discharging back the overflow to the storage tank. The high-pressure water is conveyed from the accumulator by a main, from which branches lead to all the motors. This system is almost exclusively English, and is adopted in some of our largest cities, such as London, Liverpool, Birmingham, etc. The machinery actuated is chiefly of the non-rotary class, such as hoists, cranes, bridges, etc.; but when a rotary motion is desired a hydraulic engine or waterwheel may be introduced. The usual pressure in these towns is about 750lb. per square inch, at which pressure the available energy of one gallon of water is rather more than ½ h.p.

Wire Ropes.—This system is carried out on much the same principles as the rope drive. It is perhaps seen to best advantage on the Continent, where it was introduced by Hirn, and where it is extensively used, especially so in France. The ropes used are made either of steel or iron, the former material being stronger and not so liable to stretch as iron. This tendency to stretch may, however, be lessened by passing the ropes through compression rollers previous to placing them in position. Ropes for transmission are of special make, being circular in section, and generally consisting of six strands of seven wires each, wound on a central core. A more flexible rope is made consisting of six strands of 19 wires each, both wires and strands enclosing a hempen core. The former class of rope is made up to 1½in. diameter, the latter up to 2¼in., and sometimes of a special quality of steel wire, having a tensile strength of 175,000lb per square inch of section. The size of pulleys for wire ropes should be as large as possible to prevent undue bending, and in practice they are about 3ft. for a ⅜in. rope, up to 22ft. for a 1½in. rope. Wire-rope pulleys differ from the cotton-rope style principally in the form of groove, the sides of which are usually inclined to include an angle of about 60deg. or more, and are dovetailed in section at the bottom for the reception of lagging to preserve the rope and increase the adhesion. Various linings have been tried, such as indiarubber, wood, cork, tarred oakum, and leather. Tarred oakum wound in the groove is very good, but leather has been found by experience to be the best. It is cut to the shape of groove section, and placed edge up through an opening in the side of rim of pulley, a closing piece of indiarubber being used. This lagging is said to last on an average of about three years. The breaking strength of iron rope is about 90,000lb. and steel about 120,000lb. per square inch of section, but the working tension is about 25,000lb. per square inch of section, when running at speeds up to 6,000ft. per minute. When the distance of transmission is great the rope is run on supporting pulleys placed at short intervals, or relays may be used where the rope, instead of running all the way, only runs from one station to the other, a double-grooved pulley being thus required in the intermediate stations.

Compressed Air.—Ordinary atmospheric air approaching very nearly to the requisites of a perfect gas is compressible, and this property has been taken advantage of by engineers to form a means for long-distance transmission of power. This is accomplished by means of the compressor, which is just a piston pump fitted with inlet and outlet valves of special design. The air is drawn

in during the in-stroke, and forced during the out-stroke through the outlet valves either into a receiver, or reservoir, or directly to the motors. The heat developed during compression in the compressor is got rid of in three ways: by cooling the air before compression, water-jacketing the compressor, or by introducing water in the form of spray into the cylinder during compression. The pressures in practice are from 50lb. to 120lb. per square inch, the latter pressure being generally got by means of the stage compressor, with intermediate cooling. The high pressure air is conveyed from the generating station to the motors by means of pipes laid similarly to those used in hydraulic installations. Paris and Birmingham have compressed-air systems, but in the latter town it has not been a decided success, owing to the form of joint adopted, a large leakage taking place in the main. In Paris they have been more successful, and by adopting a rubber joint they have reduced the leakage to about 1½ cubic feet per mile per hour—a very small loss indeed when the quantity of air passing through the pipe is considered. Hydraulic shock limits the speed of water in the mains to about 3ft. or 4ft. per second, but with compressed air a speed of 50ft. can be used with impunity. The greatest feats of engineering performed with compressed air has been the boring of the Mont Cenis and St. Gothard tunnels.

Electrical Transmission.—Power may be transmitted to a distance by converting energy in the form of mechanical work into energy in the form of the electric current. This is now generally performed by means of the dynamo-electric machine, which, to put it plainly, is just a machine for moving magnets past wires, or *vice versâ*, the connections being so arranged that the E.M.F.'s produced may generate currents. This is accomplished by fixing magnets round about (not on) an armature, which is a drum or ring carrying the conductors in which the current is developed and thence imparted to the circuit by means of collectors, or commutators. For a long time electricity was thought fit for nothing but the controllation of signals, but since the advent of dynamo-electric machinery, a different aspect has been given to the system, and it now bids fair to revolutionise the world. The chief application as yet made of electricity is for lighting purposes. In this case the current is conveyed by means of insulated copper wires, two of which are required to complete the circuit, the difference of potential between the wires giving the flow, the pressure of which is measured in volts, and the rate of passage in amperes. An important and increasing application of electricity is on the electric railway, where the current is supplied by means of a feeding conductor of special channel iron laid and supported on insulators between the rails. A passing connection is made between the conductor and the electric motor, which is generally fixed direct on the axle shaft, by this means saving intermediate gearing. Electricity is also coming to the front as a transmissive agent in connection with the utilisation of waste water power by the turbine. The best system yet completed on this basis is between Lauffen and Frankfort, a distance of 108 miles. The power is got from a turbine at Lauffen gearing into a dynamo, and the current is conveyed to Frankfort by means of three copper wires supported on oil insulators, which are carried on poles similar to those used in the telegraph. The efficiency of this system is said to be over 70 per cent., as out of 130 h.p. generated at Lauffen no less than 80 is delivered to the motors at Frankfort—truly a wonderful result. An installation far beyond anything hitherto attempted is at present being completed at Niagara Falls, in America, where facilities for generating and transmitting 450,000 h.p. are being fitted up, and representing a value in motive power of no less than 2½ millions per annum.

THE ROUTIN ELECTRICITY METER.

A French engineer, M. Routin, has devised, and is now manufacturing, a type of electric energy meter which is claimed to be more especially of a commercial and industrial form rather than possessing characteristics of value in the scientific laboratory. According to *L'Electricien*, to which we are indebted for details and illustrations, the Routin instrument belongs to the periodical or discontinuous registering meters, marking at fixed intervals of time, say, two, three, four, or even five minutes, the momentary value of electric energy passing through the circuit. It is considered that for all practical purposes the results thus obtained are, taking them all round, quite as reliable as those afforded by meters which are always in circuit and give a continuous record or registration, and probably this may be so in the average circuit, as no very sudden and excessive changes of load are thrown on and off within the time that elapses between the recording intervals.

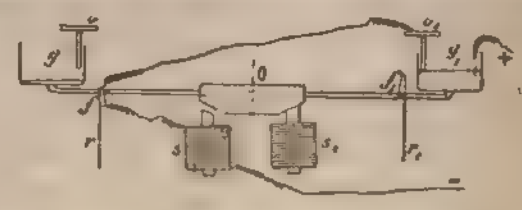

Fig. 1.

A considerable saving is thus claimed to occur in the energy required to work the meter, whilst the appliance itself may be made more strongly and with fewer parts to suffer injury or wear and tear.

After a very careful study of the requirements that are demanded from a really good and reliable electricity meter, M. Routin came to the conclusion that the following features ought to be aimed at, as being, in his mind, essential to proper working, and he has accordingly based his instrument upon them, claiming that it comes

Fig. 2.

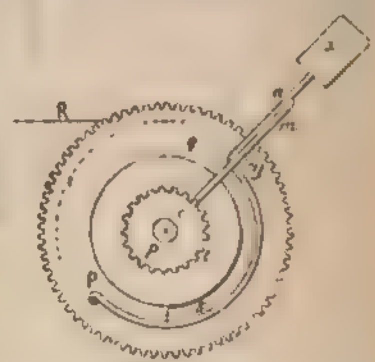

Fig. 3.

nearest to fulfilling the conditions: (1) Great exactness of readings. (2) Strong mechanical design and construction of the various parts. (3) Simplicity of same, and of the principle of working, influencing thereby the cost of manufacture. (4) Entire exclusion of all permanent magnets. (5) No springs exposed to magnetisation or other derangement. (6) No rubbing contacts, even with platinum points. (7) Calibration before sending out of the workshops, instead of in the consumer's house. (8) Great reduction in the amount of energy required to operate the meter as a registering appliance.

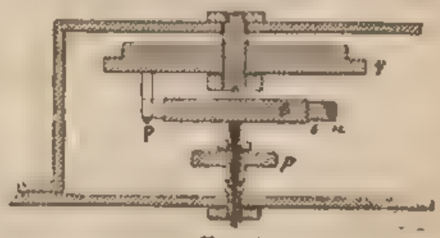

Fig. 4.

The Routin electricity meter comprises three distinct parts: (1) An electric oscillating arm, which marks exactly the interval of time desired between two successive registrations. (2) A wattmeter, giving at each fixed moment the value of the energy (E × C) passing through the circuit. (3) A train of clockwork with connecting mechanism to add up these values, thereby giving the total energy used over any required period.

The first of these parts is based upon the ancient principle of a clepsydra, or water clock, the reciprocation being effected, by means of an electric current, automatically. Fig 1 represents in diagrammatic form the outline of this oscillator, whilst Fig. 2 shows one of the details afterwards to be referred to. In Fig. 1 the oscillator appears in the shape of a fine iron tube, pivoted at O, and carrying at each end a cup, $g\ g_1$, communicating with the tube. Mercury is placed in the cups, sufficient in quantity to take an appreciable time in flowing through the pipe from one cup to the other, when the pivoted tube is tipped to one side or oscillated on its centre, O. Within the cups are two insulated screw terminals, $v\ v_1$, passing through the lids of the cups, $g\ g_1$. The tube, or pivoted arm, is maintained in position—either tipped over to the right or left—by means of two springs, $r\ r_1$, which engage with small pegs, $f\ f_1$, fastened to the arm.

Supposing that the arm has just been tilted over to the right hand side, the mercury passes along the tube and its level rises gradually in the cup g_1 until it touches the tip of the screw terminal v_1; a circuit is then closed which passes current round the electromagnet, s. A lever arm, worked by the latter (not shown in the diagram), releases the spring r_1 from the position in which it retained the arm when thrown over; the magnet, s, acts upon the iron armature fixed to the centre of the tube and pulls the latter over to the left-hand side, when the spring r catches the peg f, and maintains the arm in its tilted position. The mercury then flows from the cup g_1, along the tube to cup g, until contact is made between its level in the latter and the tip of screw v, when a corresponding circuit is made on the right-hand side, and the operations just described are similarly repeated.

The contact between the mercury surface and the screw terminal v_1 is maintained until after the spring r engages with the peg f, and in order to make sure of this, the screw terminals are set close to the inner sides of the cups, so that when the arm tips the mercury surface is inclined (as indicated in the dotted line, g_1, Fig. 1) towards the respective terminal; this gives a slightly greater depth, and a longer period of contact, than if the terminals were placed in the centres of the cups.

To prevent the sparking at the surface of the mercury, the circuit is automatically broken by rubbing contacts of platinum, as soon as the oscillation is finished and before the contact is broken between the screw and the mercury. The special arrangement of hooks on the stop-springs enable this to be done. These hooks are composed, Fig. 2, of a plate of ebonite, e, partially covered with a sheet of platinum foil, p. The latter, connected to the electromagnet, is in constant contact with the peg, c, itself connected to the screw, while the screw is not in the stop position. The circuit is thus kept closed during the time of movement, and is suddenly opened at the instant the beam reaches its position of rest. The regulation is accomplished by means of the screws, v and v_1.

Wattmeter.—The measuring part — the wattmeter — consists of a coil, B, placed near the top of the instrument (see general view, Fig. 5), of thick wire, which carries the main current; in the interior is a second coil, movable about a horizontal axis: this coil is wound with fine wire, and carries a shunt current taken across the terminals. A small counterweight exerts an inverse action to the electric couple, and keeps the fine wire coil perpendicular to the other when no current passes.

Integrating System.—Figs. 3 and 4 show the elevation and cross-section seen from above of the integrating system. This is composed of a pinion, p, gearing into a rack fixed to the oscillator. The pinion carries a finger, m, which, in rotating, meets a lever, n, at the end of which is a counter weight, x. This lever is movable on the centre, P, fixed to the wheel, q, and it is furnished with a shoe, s, which, in the movement of rotation round P, is forced against the wheel, t. This latter wheel is geared to the first wheel of the totaliser. To the wheel, q, is fixed a plug, y. The wheel is composed of two parts firmly connected, the one toothed and the other smooth; on the smooth part a spring, R, rubs, hindering its movement. The toothed part gears with a rack, C, whose upper part ends against an eccentric mounted on the axis of the wattmeter. This eccentric is cut, either empirically or as determined mathematically, so as to give the rack a movement downwards, whose amplitude is proportional to the product E × C.

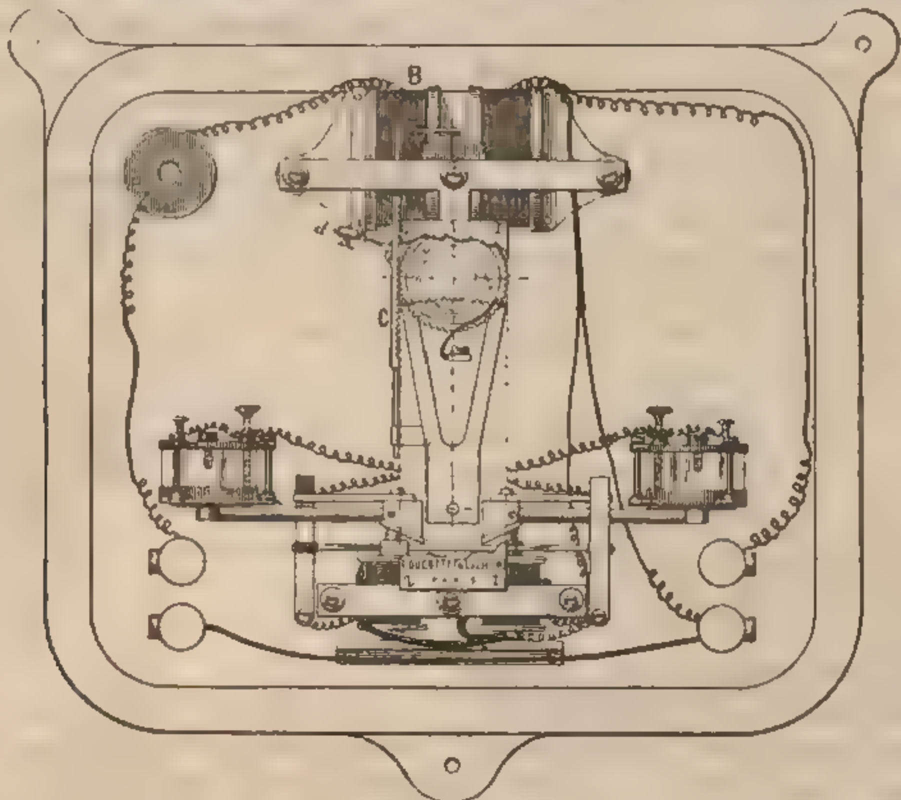

Fig. 5.

In practice, when the rack is as high as it can go, the lever, n, touches against a fixed stop, and the finger, m, draws the lever, n, by touching a spring fixed to the latter.

With regard to the mathematical determination of the curve of the eccentric, say, 90deg. + a, the angle made by the two coils, the electric couple is proportional to E C cos a, the resisting couple is proportional to sin a, whence the equation—

$$K\,E\,C \cos a = K' \sin a;$$

or,

$$E\,C = H \tan a \left(H = \frac{K'}{K}\right).$$

The equation of the curve of the eccentric in polar co-ordinates will be therefore

$$\rho = R - M \tan \alpha$$

(M being a constant, and R the maximum radius of the eccentric). To regulate the readings of the totaliser, the counterweight, x, must be shifted on the threaded stem which carries it.

The parts being thus described, the working of the apparatus, of which a general view is given in Fig. 5, will be easily understood.

During the interval of time, Θ, the pinion turns through a constant angle and comes back to its original position. When, being drawn by the ratchet, the pinion, p, turns in the direction of the hands of a watch, the finger, m, leaves the lever, n; this latter, under the action of the counterweight, x, tends to follow the movement of the finger. Under the influence of the pressure exerted by the spring, R, the lever, n, turns first around P, and the friction-shoe leaves the wheel t. But in this movement the lever meets the peg, y, and draws round the wheel q while the wheel t remains stationary. The rackwork, C, stops the movement of the wheel q when this latter has described an angle proportional to E C.

When the finger, m, turning in the reverse direction of the hands of a watch, meets the lever, n, this latter is shifted first round P, and tightens the brake, s, against the wheel t. At this time the two wheels, q and t, participate in the same movement of rotation and turn through an equal angle. The wheel q coming back to its original position, the angle described will be proportional to E C, and the totaliser will register Σ (E C Θ).

As soon as the rackwork has fallen back to its extreme position, it raises a lever, d, and puts the whole wattmeter at liberty; it fixes its momentary indication by letting the lever fall back from the beginning of its downward movement.

The system includes all the advantages enumerated at the beginning of this article; it is free of the grave defects to which the greater number of present meters are subject, notably those submitted to the competition at Paris.

The wattmeter being completely free during a time equal to $\frac{\Theta}{2}$, it can take the angle exactly corresponding to the consumption of energy. The wattmeter being braked at the moment the rackwork touches the excentric, this latter descends a space rigorously proportional to E C. The ratcheting being always accomplished with constant loss of time, the reading on the totaliser will also be absolutely exact.

The expenditure of energy required for the working of that meter is exceedingly small. Suppose $\Theta = 2$ minutes, the current will only pass into the electromagnets of the oscillator for a period equal to $\frac{1}{240}$ of the time of working. The current being about half an ampere, it will require 480 hours to consume a hectowatt, at the expense of 10c. (1d.) At an average of five hours a day, the energy consumed would come to about 40c. (4d.) a year.

Trials are being made to reduce the shunt current in the same proportion.

To apply the meter to alternate currents it is sufficient to laminate the mass of the magnet cores.

The meter is simple, strong, the regulation easy, and the fixing convenient. The meter deserves the attention of electric light companies.

INCANDESCENT LAMPS FROM THE PRIVATE CONSUMER'S STANDPOINT.

As will readily be understood from the announcements that are being made by one firm after another relative to the supply of incandescent lamps at less than one-half the current prices immediately after the expiration of the Edison-Swan Company's patents next month, the present moment is extremely opportune for bringing before our readers some figures and facts which they will do well not only to digest themselves, but also to use for the benefit of their clients—the private consumer of electricity.

The latter is an individual of many-sided character, but it may be taken as absolute that nine out of every ten persons who now enjoy the benefits of electric lighting for the interior of their premises, or who intend to do so at the earliest possible moment, are likely to feel more interest and confidence in this method of illumination, and would prove most valuable advocates of its extension, if it were shown to them that the result of free-trade in lamps means practically a large saving, not only in first cost, but also in the current used, and therefore in the total expenses.

We are shortly to be in a position to buy lamps at almost any price—from the cheap rubbish (as one is almost obliged to term it), at 1s. each, to those at 2s., with a variety of intermediate rates. The Edison-Swan Company itself—with the best possible experience and most ample resources—is asking 1s. 9d.; the Brush Company go one better, and advertise lamps from their Vienna factory at 1s. 6d.; the Zurich Incandescence Lamp Company's price is 2s., presumably because Mr. C. H. Stearn (well known as Mr. J. W. Swan's coadjutor in the early days of incandescent lamps) is giving them the advantage of his experience and energy.

In discussing, however, the economical aspects of this important development in electrical work, we shall assume as a fair price for a good reliable lamp the sum of 1s. 6d., not merely because it is the average of prices asked by the trade, but also because it allows a reasonable profit to the makers and distributors without tending too much towards the disastrous rate-cutting that usually ends in the market being flooded with absolute rubbish by unscrupulous manufacturers.

Some danger of this regrettable result is already to be feared, and both contractors and consumers cannot be too strongly warned against the short-sightedness of buying "cheap lamps and nasty."

The probability is that such lamps will neither give the candle-power claimed for them, nor will they last half as long as those made by responsible firms who have a reputation to preserve. By wasting current and necessitating constant renewals, they are indeed anything but cheap in the end.

To show consumers what real saving may be effected now that the price of lamps has dropped low enough to allow of more frequent renewals, we append some tables and other details compiled on a basis varying with the price paid for current.

TABLE A.—COST OF CURRENT, IN PENCE, PER LAMP HOUR.

		Price per Unit.			
C.P.	Watts.	5d.	6d.	7d.	8d.
16	60	·3	·36	·42	·48
16	50	·25	·3	·35	·4
16	40	·2	·24	·28	·32
8	30	·15	·18	·21	·24
8	25	·125	·15	·175	·2
8	20	·1	·12	·14	·16

Table A gives figures probably familiar already to the reader, but reproduced so that the data may be complete. It shows the cost of current in fractions of a penny per lamp hour for 8-c.p. and 16-c.p. lamps respectively, taking each three different amounts of energy for a given illumination.

Based upon this, Table B gives the total cost—*i.e.*, both of current and of renewals—over a period of 1,500 hours, which may be regarded approximately as equal to two years' lighting. The life of a 60-watt lamp is here taken at 750 hours, down to the time when it becomes too black to give the normal candle-power, even though not actually broken. Similarly the life of 50 and 40 watt lamps are assumed to be respectively 500 and 250 hours; probably all these values are well under the mark, but if so, it is to the advantage of the consumer. The price in all cases of new lamps is taken at 1s. 6d. each.

TABLE C.—APPROXIMATE TOTAL SAVING PER LAMP PER ANNUM, by substituting 40-watt lamps for 60 watt lamps; all of 16 c.p.

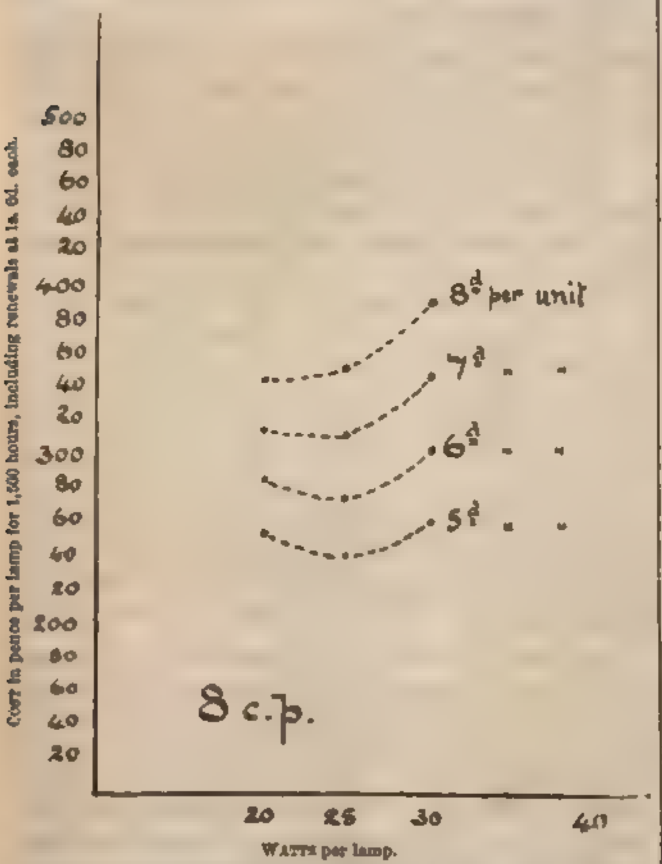
	Price per Unit.			
	5d.	6d.	7d.	8d.
Saving	3s. 3d.	4s. 6d.	5s. 9d.	7s. 0d.
Percentage	8%	9%	10%	11%

The figures of Table B show, of course, that the greatest saving is effected where current is dear—say 8d. per unit—by using 40 watt lamps. The approximate amount of total saving per lamp per annum—inclusive of renewals, in

TABLE B.—Total Cost—Current and Renewals for 1,500 Hours.

C.P.	Watts.		Price per Unit. 5d.	6d.	7d.	8d.
16	60	Current	£1 17 6	£2 5 0	£2 12 6	£3 0 0
		Renewals	0 3 0	0 3 0	0 3 0	0 3 0
			£2 0 6	£2 8 0	£2 15 6	£3 3 0
16	50	Current	1 11 3	1 17 6	2 3 9	2 10 0
		Renewals	0 4 6	0 4 6	0 4 6	0 4 6
			£1 15 9	£2 2 0	£2 8 3	£2 14 6
16	40	Current	1 5 0	1 10 0	1 15 0	2 0 0
		Renewals	0 9 0	0 9 0	0 9 0	0 9 0
			£1 14 0	£1 19 0	£2 4 0	£2 9 0
8	30	Current	0 18 9	1 2 6	1 6 3	1 10 0
		Renewals	0 3 0	0 3 0	0 3 0	0 3 0
			£1 1 9	£1 5 6	£1 9 3	£1 13 0
8	25	Current	0 15 7	0 18 9	1 1 10	1 5 0
		Renewals	0 4 6	0 4 6	0 4 6	0 4 6
			£1 0 1	£1 3 3	£1 6 4	£1 9 6
8	20	Current	0 12 6	0 15 0	0 17 6	1 0 0
		Renewals	0 9 0	0 9 0	0 9 0	0 9 0
			£1 1 6	£1 4 0	£1 6 6	£1 9 0

which the consumer naturally is interested, since he pays for them—is shown in Table C, also the percentage of saving, as between 60-watt and 40-watt lamps respectively, of 16 c.p.



In Table B, it will be noted that so far as 8-c.p. lamps are concerned the new price of lamps is still too high to allow of any material economy when current is cheap: in point of fact, the total cost of 20-watt lamps, including renewals, comes to more than that of 25-watt lamps, so that no gain is effected by the use of the former. To show this more clearly, reference may be made to the diagram, on which are marked four curves, denoting the total cost per lamp of renewals and current for 1,500 hours at different prices per unit, and for three amounts of energy required per lamp. In proportion, as the cost of current diminishes, the economy of reducing the watts per lamp is also less, and at 4d. per unit the total cost for a 20-watt lamp actually exceeds that for a 30-watt lamp.

Although, therefore, a considerable saving is effected by reducing the energy spent in lamps of 16 c.p., even at the cost of more frequent renewals, this does not wholly apply to lamps of smaller powers, and consumers may do well to bear this in mind.

The question of "overrunning" incandescent lamps is also a matter of no little importance in this connection, but requires separate treatment from a somewhat different standpoint.

THE CROSS-SECTIONAL AREAS OF STRANDED CABLES.

Assuming that a cable is made of concentric layers of wires of equal circular section, perhaps it may not be known to some that, if the copper area is given, the diameter of the core becomes greater as the number of strands is increased. Or, to take an example, a ·2 square inch core will occupy more space if made of 19 strands than if made of 7 strands.

To see this, we may suppose the space inside the insulation to be fixed, and find the ratio of the area of copper to the area of this available circular space. Now, the general term of the series 1, 7, 19, 37, ... , is $3(n^2+n)+1$, where n is the number of concentric layers round the centre strand. Hence the ratio of copper area to available area is

$$\frac{3(n^2+n)+1}{(2n+1)^2}.$$

Putting $n=0$, $n=1$, $n=2$, etc., in this expression, we find the required ratio for the different cases. The values of this ratio for the numbers of strands commonly used are as follows:

Number of strands.	Copper area / Available area
1	1
7	·778
19	·760
37	·755
61	·753
91	·752

If the number of strands is increased indefinitely the ratio becomes ·75, or $\frac{3}{4}$.

And, similarly, in three dimensions we can find that a pint of small shot will contain less lead than a pint of buck shot, provided that a number of concentric layers will fit in exactly in each case, and that the pint measure is cylindrical. If a measure of square section were used, supposing an exact fit, the amount of lead in the two cases would be the same.

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE BRADFORD ACCOUNTS.

The detailed accounts given elsewhere, as prepared by Mr. J. N. Shoolbred for the Bradford Corporation, contain a refutation to the absurd criticisms so often met with upon municipal action as regards electric lighting. We assume that sooner or later the accounts of other municipal electrical undertakings will be presented in like manner to these of Bradford. One of the criticisms to which we refer runs as follows: "Probably, like the Vestry of St. Pancras, the Dublin Corporation think it unnecessary to begin to allow for depreciation just yet, but this forbearance will only make matters worse in the near future." There are other equally insane criticisms, but this one will be sufficient to form a text for our present purpose. Let us candidly admit our aim to be to induce local authorities to undertake electric lighting; hence the reason for explaining what is really done, and disarming such statements. Municipalities against companies is the text. The former borrow money at, say, 3 per cent., but have to repay the capital in twenty-five or thirty years. This involves a sinking fund at the rate of little over another 3 per cent. A municipality has, therefore, no capital expenditure at the end of thirty years. A company has a capital that figures in the balance-sheet for ever. The one pays 6 per cent., and rids itself both of interest and capital; the other pays 6 per cent. and does nothing of the kind. Examine a little closely into the figures of Bradford as prepared by Mr. Shoolbred. It is evident that the plant is kept in repair and in the highest state of efficiency out of revenue. The interest on capital and the sinking fund to liquidate capital have been paid from the first. It seems to us that a sinking fund, if it means anything, means depreciation, and if you depreciate in one way it is not necessary to depreciate in another. Given, however, that there is a surplus after providing interest and sinking fund, as there is at Bradford, we have a further safety provision in the shape of a reserve fund. If the loans are paid off by instalments periodically, the interest on the loan must decrease proportionately, and the reserve rapidly increases. Of course, in the account as presented the capital has increased, but that is due to further expenditure, and has no bearing upon our argument. That further expenditure is undertaken to enable more work to be done, and thus a greater revenue to be obtained. The excess of revenue so earned is used to pay interest and provide sinking fund for the extra capital. One question might well be debated. Is the capital account extinguished rapidly enough by means of the sinking fund provided? We think yes—in fact, we should say, a little too rapidly; and no doubt if the Bradford authorities find the balance put to what we have termed the reserve fund increases rapidly, they will still further reduce the price of current, or take a certain proportion to diminish the rates. They will, in fact, have to decide whether it is best to relieve the ratepayer directly by appropriating profit, or indirectly by lowering his light and power bills. It will be seen that local authorities not only do depreciate, but they must depreciate:

they only obtain their capital on these terms; and critics who are so ignorant of municipal affairs as the one we have quoted above shows himself to be, ought to take a few lessons at some twopenny night school upon municipal economics. In the figures relating to Bradford, no doubt it will be noticed how for some time past the working expenses approach about 50 per cent. of the receipts, and again it may be surmised that the large number of units sold during the half-year ending June 30, 1893, is due to the increase of electrical energy for motive power rather than for light. We commend these figures for careful examination to every municipal authority.

LEEDS TRAMWAYS.

According to the views expressed by the Highways Committee of the Corporation, there is some hope for an extension of electric traction in Leeds. Most of our readers are acquainted with what has taken place in Leeds with regard to tramways during the past three years. Previous to that period there were tram lines to Roundhay Park, or rather to a point which ended at nowhere, leaving the would-be visitor to the park to walk the balance of the way. Some few feeble attempts were made to work this line, but unsuccessfully, and it seemed of the nature of a white elephant. Mr. Graff Baker came along, and with that energy born of contact with American soil entered into an agreement to work the Roundhay line electrically for two years. The working was successful, though the reward was perhaps less pleasing; but we have it on the best authority—that of users of the line—how great was the comfort and convenience of the service to those who lived in the district. It ought also to be said that the district was and is largely undeveloped, and that the town end of the line is inconveniently away from business centres. Two years passed and a further agreement was entered into for one year, and this third year of working expires, we believe, at the end of the present month. Meanwhile, the authorities have been considering the question of purchase of all rights not in their hands to the tramway lines, and arbitrators have practically agreed what is to be paid. The committee expect to be in possession shortly, and have agreed temporarily to work the lines themselves. Application is to be made to the Board of Trade for permission to borrow £130,000 in connection with this tramways purchase. The tramways are of three kinds—those worked by horse traction, those by steam traction, and those by electric traction. What principle of traction will ultimately be adopted is difficult to say, but the committee seem open-minded with, if we may say so, a slight bias towards electricity, and have determined to visit the Staffordshire lines in a body, though a sub-committee has been that way before. Mr. Dickenson will have thus an opportunity of explaining the various modifications he has introduced in these lines, so as to avoid some of the many evils of overhead traction. We are convinced that under proper guidance the Leeds authorities could not do better than to adopt electric traction. Preparatory to this, however, or contemporaneously therewith, they should acquire the electric lighting central station, and in the development of the electric light lay down power mains in addition to the light mains. There is no valid reason why the system adopted should not be partly overhead, partly conduit, and partly self-contained. If electrical engineers have any information of value, now is the time to influence the Leeds authorities. The decision once taken will be fatal to the use of some one or two forms of traction in the town, and it is to be hoped that electric traction will not be one of them.

REVIEWS.

The Dynamo: Its Theory, Design, and Manufacture. By C. C. Hawkins, M.A., and F. Wallis, A.I.E.E. Whittaker and Co.

This is a work of no mean ability, especially if viewed from the standpoint of a collection of valuable information. To criticise it exhaustively would mean the writing of another treatise, for opinions still differ as to the interpretation of many electrical matters. Hence, while trying to indicate the contents of this book, it will be impossible to discuss the many conclusions with which we heartily, or do more than cursorily examine some with which we do not, agree. That differences of opinion upon highly controversial matters exist does not detract one iota from the merit of a book. In the introductory chapter the authors point out the dual character of a dynamo which arises from the dual nature of electricity; not the dual nature, as ordinarily understood, of vitreous and resinous, or positive and negative, but from the dual phenomena of current and field. A glorious question for discussion would be the possibility of current without field or field without current. So long, however, as Ohm's law holds good, those who argue on the side of impossibility must have the advantage. Energy is discussed, as is the transformation of one kind of energy into another kind by means of the dynamo. Then chapters are devoted to "magnetic field" and "the magnetic circuit." With regard to the former all books assume too much of the student, and for the sake of condensation leave him with uncertain, if not incorrect, views. Such sentences as the following require amplification and explanation: "The lines of force indicated by the filings are crowded together near the poles where the force is strongest, and gradually widen out until where the force is weaker they are comparatively widely scattered." We take it that the authors believe in the "magnetic circuit"; indeed, the book is built upon this assumption, and, therefore, that lines of force must be closed curves. If that is so, the force through any given cross section of a field is absolutely and identically the same as that through any other cross section. If, however, we talk about the force through a given area of such cross section, then the sentence may be made to indicate the correct view. The density of lines per unit area is greater in the air-space near the poles than further away, and is usually greatest per unit area within the body of the magnet. The authors of text books, as a rule, are compelled to follow the teachings of the day. It is only now and again that an utterly unorthodox book is issued, and that usually at a heavy cost to the author. He airs his opinions and pays the piper. Hence, though we should prefer a closer assimilation of magnetic circuit nomenclature to conductive circuit nomenclature, and use the term resistance rather than reluctance, we cannot expect the authors to do so; nor would it be wise for them to disparage μ, although the value of μ is merely that of a coefficient which, when multiplied by the magnetic reluctance (resistance) of air, gives a product indicative of the magnetic reluctance of the substance for which that particular value is the coefficient. Permeability is a term really no more required as regards the magnetic circuit than it is in the

conductive circuit. If, however, the resistance of air is to be accepted as the standard magnetic resistance, it may be useful to tabulate magnetic resistances by the aid of a co-efficient. Still, we are advancing. It has only been during the last few years that the term "magnetic circuit" was tolerated in high scientific circles. Now we are so far advanced, we must advance further. This is how matters now stand:

Conductive Circuit.

Unit of E.M.F., the volt.

Unit of resistance, the ohm.

Unit of current, the ampere.

Magnetic Circuit.

Unit of resistance, none.

Practical comparisons are made from formula $\mu \times$ reluctance of air.

Unit of magnetomotive force, none.

Practical comparisons from $\cdot 4\ \pi$ ampere-turns.

Unit of number of lines of force, none.

Practical comparisons from a ratio, $\dfrac{\cdot 4\ \pi \text{ ampere-turns}}{\mu \times \text{resistance of air}}$.

Coming to the chapter on the production of E.M.F., have not the authors used the term "inductor," p. 41 and subsequently, in a sense not usual? The whole paragraph, too, needs amplification. It is true that you may move a conductor about in a field without getting indications upon an electrometer, but in the first place you have got to get your conductor into the field, and that cannot be done without indications, nor can it be taken out of the field without indications. This chapter will bear careful reading, as will the following chapters on magnetic pull and self-induction, especially the latter, but in the former we think the authors' definitions are not correct, yet as once defined, like "inductor," they hold to the definitions consistently, so that the reader has merely to be careful in getting the definitions. Chapter VII. treats of the classification of dynamos, pointing out that all dynamos consist of two main parts—one constituting the apparatus to obtain the field, the other the armature—and considering all the variety of designs as belonging to one of two classes: (1) those in which the "inductor" cuts the same lines twice over in opposite directions in each revolution; and (2) those in which each "inductor" when cutting lines is always cutting them in the same direction. The latter class are unipolar dynamos, the former all bi or multipolar. The general designs in the two classes are considered and the various actions explained in detail. One valuable feature throughout the book is the excellence and number of the illustrations. A mass of very interesting information about types of armatures will be found in this and the succeeding chapters, which deal respectively with "bipolar and multipolar alternators," "unipolar alternators," "open-coil armatures," and closed-coil armatures. Due credit is given to the pioneers in armature design—Pacinotti, Gramme, Siemens, Von Hefner Alteneck—and if after digesting these chapters the reader has not obtained a fair grasp of the variety of design, he never will.

(To be continued.)

THE RETURN CIRCUIT OF ELECTRIC RAILWAYS.*

BY THOS. J. M'TIGHE.

I have had the honour of being appointed a special committee to make a report upon "The Return Circuit of Electric Railways. To show you that the magnitude of the honour has been appreciated, and the gravity of its duties well weighed, I may say that during the whole interval the committee has been in session every day and night, including Sundays. I may also add that a committee so continuously controlled by the pernicious one-man power has hard work reaching sound and impartial conclusions upon the questions forming the subjects of deliberation at the sittings. One leading difficulty has been to obtain some crumbs of certainty from the confusing experience of others. At one sally of the committee, after deciding that iron rail bonds were only worthy of execration (and rust), we were told that nothing but iron is trustworthy. Another opinion, obtained the same day, and also based upon alleged long experience, was that the bonds should be copper and the ends or rivets soft iron. The heathen who gave this opinion, I am glad to say, has since come into the fold. Still another, also a man of experience, announced that rail bonds were all wrong, that the only thing to do was to lay a No. 0 supplementary copper wire and connect each rail to this by a soldered branch terminating in a copper rivet soldered to it and simply driven into the rail at any convenient point. That made harvest enough for one day. The committee went home and entered into executive session, and decided to remain in executive session indefinitely, and try to get at the question in its own way, since at the outset it got a knockdown blown for attempting to believe the doctrine *experientia docet* to be infallible.

The progress of the trolley system of electric railways has been so rapid as to become almost bewildering. A multitude of improvements had been added, the necessary result of careful thought and ingenuity of the electric engineer, and the critical study of the practical railway manager and his assistants. But this has been mostly true of the track and overhead construction and the cars and power equipment The return circuit has been rather neglected, being largely a case of "out of sight, out of mind." Originally installed on a basis evidencing immature study, and necessarily without experience, it has been left to shift for itself, or rely upon Mother Earth to open a frictionless path for the nearly exhausted pressure to get back to the power-house. Few practical investigations of efficiency have been made, and data are meagre. Yet the return circuit is in some respects quite as important a factor of the system as the overhead circuit, and a moment's thought will show this to be true. The efficiency of an electric circuit depends upon the resistance of all the parts. We carefully figure out the amount and size of overhead wire, so as to bring down the waste of energy in transmitting current to the motors, and we should be logically bound just as carefully to plan out the return circuit. There is this important difference, too, in our favour in the latter case, that while we must have all copper overhead, and consequently must struggle with the spectre of cost, when we get in the ground we have a veritable tower of refuge present in the rails, if we but choose to take proper steps to avail ourselves of their valuable help. Track rails are necessary, and they are getting better and bigger for our circuit purposes, and I believe that it will not be long before the absurd and costly supplementary wire will have joined the vast army of discarded "expedients," and with it the earth as a permanent part of the return circuit, except in some special cases.

On a wet day in moderate weather the earth is available, and to a very large extent, I believe, considering that with a 70lb. girder rail and double track we have something like 30,000 square feet of earth contact per mile of track. But we cannot rely upon this doing us the same service in long spells of dry weather. Still more, we cannot rely upon it doing any good whatever in severe winter weather. It is not uncommon in this State for frost to penetrate 3ft. in the ground, and to stay there for a whole winter. Under such circumstances the earth return must go out of our calculation. It is during severe winter weather that we want to realise our very last watt in the hard pulls we must contend with almost daily.

We are told in mechanics that the strength of a structure is measured by that of its weakest part under the most unfavourable conditions it is to meet. Similarly, in a compound electric circuit, the total resistance must depend upon the condition of highest resistance to be met with in any of its component parts. We must plan so as to have our return circuit efficient in the most prolonged summer drought, and in the most severe frosts of winter. Ground plates and pipes laid below permanent water-level are a refuge in a few favoured localities, but the same can hardly be said of plates and pipes laid in the ground whose moisture depends upon the wayward elements.

* Report read before the Street Railway Association of New York State, September 19, 1893.

I have made a large number of calculations as to what should be the total resistance per mile of the return circuit under different methods of the construction of the circuit. In making these calculations I have eliminated the conductivity of the earth, because in average winter weather the earth turns a very cold shoulder to the track. I have eliminated the conductivity of the fishplates, because I believe that under average conditions the comparatively small areas of contact surface are too much oxidised to be of much benefit. The most approved form of fishplate bears only at its upper and lower edges against the rail. The rail and plates are merely special forms of structural steel, rolled while hot, heavily oxidised at best, and usually rusted still more before being applied. Two such rolled surfaces never come into good contact throughout, and it cannot be expected. A straight-edge laid along the bearing surface of the ordinary fishplate will convince anyone who takes the trouble. Even on our magnificently constructed and continuously maintained steam trunk lines I have, on examination with my knife blade, rarely found a fit so perfect that I could not enter the blade at one or more points.

I have eliminated all the refinements upon which exact scientific analysis of the subject would insist, such as changes of temperature, moisture, and other conditions which are more or less insignificant in the practical work. I have based the figures on the ratio of 6 to 1 in comparing the resistance of the ordinary soft steel rails with that of our usual commercial copper, and for the latter I have followed the ordinary tables adopted by the wire manufacturers.

I have not discriminated between the different assignable values for resistance in the various forms of rail bonds, and have calculated only for the specific metal used in the comparisons, leaving the merits and demerits of the form out of the question. I will refer to the last later on.

In studying general situation prior to constructing, in the spring of 1891, the railway system of Lincoln, Neb. (of which my firm were supervising engineers), I investigated the subject somewhat closely. Though at the time, and under the local conditions, an advocate of iron rail bonds, I was and am yet convinced that supplementary ground wires are an unwise extravagance. I will try to give you the reasons for this belief.

In steel rails we usually say that every 10lb. weight per yard means one square inch of cross-sectional area. And every square inch of such area can be brought to terms of copper by dividing by 6. The resistance is easily determined, and we thus readily arrive at some important results for comparison. For example, take the average city railway rail as being a 70lb. girder. Its area is substantially seven square inches, and the four rails of a double track make 28 square inches, equal to a single steel bar 4in. thick by 7in. wide. This is electrically equal to a bar of copper having 4·66 square inches area, or, in other words, a copper conductor 1in. thick and almost 5in. wide. With such a magnificent path for our returning current, does it not seem absurd to supplement it with a No. 0 wire, whose area is that of a rod a little over a ¼in. square? But when we find the above rail resistance per mile to be but ·0086 ohm, while that of the No. 0 wire is just 60 times greater, the absurdity seems to grow, and it becomes a case of sending a very small boy to do a very big man's work with the man standing idle on the spot.

Calculating in like manner for some usual weights of rails, I obtain Table I.

TABLE I.—Double Track.

Size of rails.	Total sectional area.	Equivalent in copper.			Resistance per mile.
		Area.	Thick.	Wide.	
lb.	sq. in.	sq. in.	in.	in.	ohm.
50	20	[illegible]	1	3 33	0·0121
60	24	4·00	1	4·00	0 0101
70	28	4 66	1	4·66	0 0086
80	32	5 33	1	5 33	0·0075
90	36	6·00	1	6·00	0·0067

As it would be tedious to carry all these into further comparisons, I will carry the analysis out mainly on the 70lb. rail, with one reference to the big 90lb. rail now being extensively used in large cities.

TABLE II.—70lb. Rail, Double Track.

Case.	Description.
1	No. 4 copper bonds, connectors, and two No. 0 copper supplementaries.
2	No. 4 copper connectors to rail ends, two No. 0 copper supplementaries.
3	36in. No 0 iron bonds, single. No supplementary.
4	36in. No. 0 iron bonds, double. No supplementary.
5	36in. No. 0 copper bonds, single. No supplementary.
6	12in. No. 0 copper bonds, single. No supplementary.
7	36in. No 00 copper bonds, single. No supplementary.
8	12in. No 00 copper bonds, single. No supplementary.
9	36in. No. 000 copper bonds, single. No supplementary.
10	12in. No. 000 copper bonds, single. No supplementary.
	90lb. Rail, Double Track.
11	No. 4 copper connectors to rail ends, four No. 0 supplementaries.
12	12in. No. 0000 copper bonds, double. No supplementary.

Cases 1, 2, and 11 are given as representing the system on which probably a large majority of electric railways have been constructed. A few roads have the supplementary doubled along both tracks, and a few have used slightly larger connecting wires than No. 4 B. & S. But I am trying to give the average of what has been accepted as first class work, and will try to show it can be vastly improved. The West End and the Brooklyn City Railroad Companies laid their tracks with double supplementary copper wires (No. 0 B. & S.), but found them totally inadequate, and now have put up many miles of huge return feeders or mains at great cost. Even these are inadequate. In Brooklyn these return mains (500,000 circular mils) are, when possible, suspended on the elevated railroad structure. I am informed that occasionally the insulation scrapes off and the return main makes contact with the ironwork. Heat enough is developed at this leak to soften the insulation for many feet, thus showing that the resistance of the main return is still too high.

Taking the various cases set forth in Table II., I have constructed another table, and for the sake of fair comparison I have made the calculations on the same basis of elimination as previously noted. I am not aware that the subject has heretofore been followed up to this extent, and I think it will be found interesting, and perhaps important.

Of course, in localities favoured all the year round with wet ground, the above table would be seriously astray; but, as I have said, the table is based upon the most unfavourable condition—namely, earth frozen hard for 2ft. or 3ft. deep, and earth conductivity practically nil.

(*To be continued.*)

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE I.

(*Concluded from page 305.*)

Variation of Efficiency and Fuel Consumption in Internal Furnace or Explosion Engines.—Gas and liquid fuel engines receive their charge at atmospheric pressure as well as exhausting into the atmosphere. Hence in a complete cycle the resultant back pressure loss is comparatively small. The engine friction, however, is rather larger than in steam engines, and appears to be independent of the load. Hence the mechanical efficiency decreases at light loads. Also at light loads the combustion is in some cases less perfect, or proceeds more slowly, and this is a cause of loss. It is well understood that gas and petroleum engines should be worked as far as possible at full load. At the Dessau electric station, which is worked with gas engines, large secondary batteries are used to store the surplus energy when not required for supply, and to obviate the necessity of working the engines at light load. On the other hand, engines of this type have the very great advantage that they can be started in a few minutes when required, and stopped whenever they are not wanted. There is, in a station worked with such engines, no loss like that due to irregular working of the boilers.

* Howard Lectures delivered before the Society of Arts.

TABLE XI.—Fuel Consumption in Internal Furnace Engines.

Brake load in per cent. of load at full load.	Gas engine Cubic feet of gas per brake h.p. hour.	Oil engine. lbs. of oil per brake h.p. hour.
100	21·65	1·00
75	23·78	1·13
50	28·05	1·40
25	40·85	2·20
12½	66·45	3·80

It will be seen that the cost in fuel per horse-power increases greatly at light loads.

COST OF STEAM POWER.

The probable cost of steam power in any given case can only be determined by careful estimates in which local conditions are taken into account. The cost of coal, facilities for obtaining water, the cost of labour, even the type of engine and character of the buildings required, are more or less different in different cases. Certain typical cases may, however, be taken, and an average estimate made of the cost in such cases. The cases will be taken first of engines used in industry and working a regular number of hours daily with a nearly regular load. This will afford some indication as to how far motive power, supplied from central stations by some method of transmission, can be used economically in place of power generated locally by steam engines. Then the special case of the cost of power generated by steam in central stations for distribution will be considered.

Cost of Engines, Boilers, and Buildings.—With engines of 100 h.p. or more, the cost can be pretty definitely stated, and the total cost of engines and boilers per horse power does not vary very greatly with the type of engine adopted. For if a cheaper and simpler type of engine is selected, then, its efficiency being less, the boilers have to be larger; but, with small engines, the cost per horse power increases very considerably, both because small engines are less efficient, and because they are more expensive to construct.

It will be assumed for the following estimates that the total cost, erected, of engines and boilers, with pipes and auxiliary apparatus, and such buildings as are necessary, may be taken to be as follows:

TABLE XII.—Cost of Steam Plant.

Indicated h.p.	Cost per i.h.p. in £.	Effective h.p.	Cost per h.p. in £.
1	56	·7	80
10	30	7·5	40
50	24	40	30
200	20	165	25

In determining the annual cost, interest will be taken at 5 per cent., and maintenance (repairs) and depreciation at 7½ per cent.

Cost of Coal and Petty Stores.—In the following estimates coal will be taken at 20s. per ton. The amount of coal required must be calculated so as to allow for lighting up boiler furnaces; for waste due to cooling of boilers and brickwork when steam is let down; and for working auxiliary apparatus, such as feed pumps.

TABLE XIII.—Working Cost of Steam Plant.

Indicated h.p.	Coal per i.h.p. hour.	Effective h.p.	Coal per effective h.p. hour.
	lb.		lb.
1	8	·7	11½
10	5¼	7·5	7
50	2¾	40	3½
200	2·0	165	2¼

The cost of petty stores will be taken at 0·25lb. per effective horse-power per annum in the case of moderately large engines working 10 hours a day. In other cases a proportionate estimate will be made.

Cost of Labour.—For driving, stoking, and cleaning an allowance of £1·2 per annum per effective horse-power for 3,000 hours, or £0·6 per annum for 1,000 hours, will be made. In the case of engines of 10 h.p. or less, however, the labour reckoned on the horse power costs considerably more.

The results given in these tables are plotted in Figs. 8 and 9. The extremely rapid increase in the cost of working for small powers is very striking.

Annual Cost of an Effective Horse-power per Annum obtained by an Engine Working with Dowson Gas.—It will be useful to place alongside these estimates of the cost of a steam horse-power an estimate of the cost of a horse-power obtained from a gas-engine. For comparison, the very careful estimate of Prof. Witz may be taken, based on experimental trials of an engine of 112 i.h.p., or 77 effective horse power, worked with Dowson gas. The total cost of the engine, with pump and pipes, was £944, or £8·2 per indicated horse power. The gas generator cost £280, or £2·5 per indicated horse power. Foundations and erection (without buildings) cost £68, or £0·61 per indicated horse-power.

TABLE XIV.—Cost of an Effective Horse-power per Year of 1,000 Working Hours. The Engine Working Regularly with Nearly Full Load.

—	Indicated horse-power of engine.			
	1	10	50	200
	£	£	£	£
Interest at 5 per cent. on engines, boilers, and buildings	4·00	2·00	1·50	1·25
Maintenance and depreciation at 7½ per cent.	8·00	3·00	2·25	1·88
Coal at 20s. per ton	5·13	3·12	1·56	1·01
Petty stores	0·50	0·30	0·20	0·15
Labour	6·25	3·00	0·80	0·70
Total cost of one effective horse-power per year of 1,000 hours	23·88	11·42	6·31	4·99
Cost (in pence) per effective horse power hour	5·75	2·84	1·51	1·20

TABLE XV.—Cost of an Effective Horse-power per Year of 3,000 Working Hours. The Engine Working Regularly with Nearly Full Load.

—	Indicated horse-power.			
	1	10	50	200
	£	£	£	£
Interest at 5 per cent. on engines, boilers, and buildings	4·00	2·00	[illegible]	1·25
Maintenance and depreciation at 7½ per cent	6·00	3·00	2·25	1·88
Coal at 20s. per ton	15·39	[illegible]·36	4·68	3·03
Petty stores	0·75	0·45	0·30	0·25
Labour	12·50	6·00	1·50	1·20
Total cost of an effective horse-power per year of 3,000 working hours in pounds	38·64	20·71	10·23	7·61
Cost of an effective horse-power hour in pence	3·10	1·66	·82	·61

The total cost, without buildings, was therefore £11·5 per indicated, or £17·2 per effective horse-power a cost about equal to that of a steam engine plant of the same power. Prof. Witz takes the cost of anthracite at 25s. a ton, and coke at 28s. a ton. He allows for interest and depreciation 15 per cent. The gas consumption is taken at 84 cubic feet per effective horse-power hour, which allows nothing for irregular working. Prof. Witz's figures are reduced to a year of 3,000 working hours.

TABLE XVI.—Cost of an Effective Horse-power in a Gas engine, using Dowson Gas, per Year of 3,000 Working Hours.

Interest and depreciation at 15 per cent.	£2·78
Anthracite and coke	2·36
Petty stores	·40
Wages	·96
	6·50

The cost appears to be slightly less than that of a steam-engine of corresponding power. The cost is equivalent to 0·51 pence per effective horse-power hour.

Cost of Steam Power in Central Stations.—The case of a central station worked by steam power differs from those previously considered in consequence of the excess of plant required, and the waste due to working against a varying load.

In such a generating station, whether supplying electricity or energy in any other form, it is usually necessary to work night and day. Part of the engines must work 8,760 hours in the year; but for a large fraction of the time much of the plant is standing idle. The demand for motive power purposes is greatest during the day hours, that for lighting during the evening hours; during part of the night the demand for any purpose is very small. It follows that the plant required must be much larger than that which would be required to meet the average demand if that could be supplied uniformly during the 24 hours. Further, there must be a reserve of power, so that any engine or boiler can be laid aside for examination or repair without hindering the work of the station. That reserve will be taken to be 25 per cent. of the whole power.

The earning power of the plant depends on the average demand and average rate of working. The coal and labour depend on this also, but are increased in consequence of the uneconomical conditions of working. The interest and depreciation must be calculated on the maximum output of which the plant is capable.

Working Cost of Engines Reckoned also at per Indicated Horse-power at Full Load.—The cost of coal will be taken at 7s. per ton. The cost of oil and petty stores will be taken at £0·28 per indicated horse-power per year. Labour is a difficult item to estimate, because it depends so much on management and conditions of working. The cost of labour will be taken at £2 per

indicated horse-power. The following rates will be assumed for interest and depreciation:

	Per cent.
Interest on capital cost of plant	4
Maintenance and depreciation:	
Buildings	2
Machinery	7½

From what has been said, it will be seen that the annual cost of a horse power depends on the distribution throughout the day of the work to be done. If the work is regular, and the engine works at nearly full load, the cost of the horse power is comparatively small; on the other hand, if the work is very irregular, larger engines are required, the working is inefficient, and the cost is comparatively large.

Two limiting cases will be considered:

Case I.—Conditions similar to those of an engine pumping to reservoirs night and day all the year round. Such an engine may be taken to work 90 per cent. of the whole year, or of 7,884 hours in the year. For one effective horse-power of work done there must be exerted 1/0·85 = 1·176 i.h.p., allowing for engine friction. And for every 1·176 i.h.p., engines of 1·47 i.h.p. must be provided to allow the necessary reserve.

Case II.—Engines working in conditions similar to those of an electric lighting station. The engines work all through the year, but the maximum demand is four times the average demand. For every effective horse power the engines must exert, neglecting the variation of mechanical efficiency, 1·176 i.h.p., and for every 1·176 i.h.p. of average demand there must be provided engines capable of exerting 4·70 i.h.p. during hours of maximum demand. Further, to allow a reserve, the engine power in the station must be 5·87 i.h.p. for every effective horse-power of average demand.

Case I.—Engine Working on a Very Regular Load, in Conditions similar to those of an Engine Pumping to a Reservoir.—Here, for one effective horse-power exerted during 7,884 hours annually, engines of 1·47 i.h.p. must be provided. Such engines may be taken to use 14lb. of steam per indicated horse power in test trials; but in ordinary work, 7½ per cent. more must be allowed for leakage, working auxiliary engines, and less careful attention. This makes the consumption 15lb. of steam per indicated horse-power, or 15 × 1·176 = 18lb. per effective horse-power hour. At 9lb. of steam per pound of coal, allowing also 5 per cent. for lighting and banking fires, the engine would use 2·1lb. of coal per effective horse-power hour. There are very few engines working with quite so low a consumption.

Cost of Installation.

Cost of engines for 1 effective horse-power or with reserve 1·47 i.h.p. = 1·47 × 8·9	£13·3
Cost of boilers = 1·47 × 4·8	7·0
Cost of buildings, 1·47 × 6·0	8·8
Total	£29·1

Annual Cost of Working per Effective Horse-power.

Interest at 4 per cent.	£1·164
Maintenance and depreciation:	
Buildings, at 2 per cent.	0·176
Machinery, at 7½ per cent.	1·522
Total fixed annual cost	2·862
Coal, 2·1lb. for 7,884 hours, at 7s. per ton	2·587
Petty stores	0·327
Driving, stoking, and cleaning	2·334
Total annual cost	£8·110

This is equivalent to 0·24 pence per effective horse-power hour.

Case II.—Engines Working with Very Variable Load in Conditions similar to those of an Electric Lighting Station.—Here, for one effective horse-power supplied, on the average throughout the year, engines of 5·87 i.h.p. have to be provided. On account of the inefficiency and waste due to the variation of the load, it is best to estimate the steam and coal from experience in similar cases. Probably, no electric lighting station at present works with quite so low a consumption as 6lb. of coal per hour per electrical unit supplied. A consumption of 9lb. is probably much more common in the best-managed stations. Six pounds of coal per electrical unit corresponds to 3·8lb. per effective horse-power hour.

Cost of Installation.

Cost of engines for one average effective horse power, with reserve 5·87 i.h.p. = 5·87 × 8·9	£52·2
Cost of boilers = 5·87 × 4·8	28·5
Cost of buildings = 5·87 × 6·0	35·2
Total cost	£115·9

Annual Cost of Working per Effective Horse power.

Interest at 4 per cent.	£4·64
Maintenance and depreciation:	
Machinery, at 7½ per cent.	6·05
Buildings, at 2 per cent.	0·70
Total fixed annual cost	11·39
Coal, 3·8lb. for 8,760 hours at 7s. per ton	5·20
Petty stores	0·33
Driving, stoking, and cleaning	2·33
Total annual cost	£19·25

This is equivalent to 0·51 pence per effective horse-power exerted on the average throughout the year.

Cost of a Horse-power at Existing Electric Lighting Stations.—It is, perhaps, not entirely fair to take the cost of working of electric lighting stations as a guide to the cost of steam power. They have been recently established, they work under difficult conditions, and the best methods of economising cost have probably not yet been arrived at. On the other hand, they are central stations of the kind discussed in these lectures, and accounts of the cost of working are published in returns made to the Board of Trade.

To be as fair as possible to electrical engineers, the case of Bradford may be taken, where, according to the returns, a unit of electricity supplied is generated more cheaply than at any other station. In dealing with the figures in the returns, the cost under the heading "Salaries of manager, engineer, etc.," and that under the heading "Redemption fund," are discarded. Further, half the cost under the headings "Depreciation" and "Repairs and maintenance," is also subtracted, because under these headings are included charges not belonging to the cost of generating power. It would not make much difference if a larger or smaller fraction had been subtracted. After making these deductions, the cost of a unit of electricity supplied at Bradford mainly, if not entirely, attributable to the cost of producing power is 2·1d. Now the mechanical value of an electric unit is 1·34 horse-power hours. Taking the average efficiency of the dynamo at 0·85, then one unit corresponds to 1·34/0·85 = 1·57 effective horse-power of the engine. Calculated on this basis it

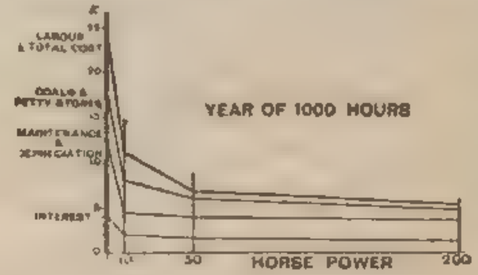

Fig. 8.

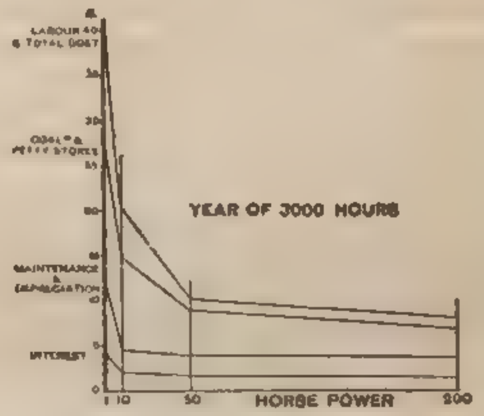

Fig. 9.

appears that the cost of an effective horse-power per year of 8,760 hours at Bradford is £49. The cost of coal and petty stores alone, exclusive of all charges for labour, interest, and depreciation, is £14·6. At most other stations for which returns are made, the cost reckoned in the same way is considerably greater.

BRADFORD CORPORATION ELECTRICITY SUPPLY.

[The Bradford Corporation being the first to elect for electric lighting has had the longest experience, and its periodic accounts are carefully read and examined by many authorities. We have pleasure in now giving the latest report, bringing the accounts up to June 30 of this year, and venture to say that these figures prove beyond all doubt the success of the undertaking.—Ed. *E. E.*]

By the desire of several members of municipal corporations, and of others interested in the development of the application of electrical energy to industrial and other purposes, I have prepared the following brief description of the progress of this, the earliest municipal undertaking of its kind, from the commencement to the present date. By the courtesy of the Bradford Corporation there is also appended a brief but complete financial statement, taken from the official six monthly accounts of the Corporation. The object of this descriptive statement being not merely to illustrate the commercial success which has attended this enterprise, but also to refute the grave misstatements respecting this electric

installation which have been made by persons who cannot plead ignorance of the subject. These misstatements, which have appeared in the public newspapers, refer to the Bradford electricity supply (and to others laid down upon similar lines) as being a mistake, both electrically and financially and one not likely to be again repeated by other municipal bodies. The fact, however, that this electrical enterprise (as the accounts show) has, within three years from the commencement of the supply, not merely met all its current expenses, including the interest on borrowed capital, and its proportion to the sinking fund for the repayment thereof, but has also paid off all of those expenses which had accrued during the construction of the works, and yet can manage, besides the above payments, to set aside regularly a further balance, and a substantial one, too, towards a reserve fund for depreciation of plant, is one that is not likely to prejudice municipal authorities against this or other similar "continuous"-current "low pressure" installations. Especially, when the relative financial position of the electrical companies using the above system, and of those employing "high pressure alternating currents" as evidenced by the Stock Exchange quotations of their respective shares shows so much, generally, to the disadvantage of the companies using alternating currents. There is yet another matter which is forcing itself into prominence, and of which municipal authorities, at least, must take cognisance. It is the fatal and unfortunately increasing number of casualties which have resulted from the use of "high pressure" combined with the "alternating" current.

JAMES N. SHOOLBRED, M.I.C.E.

13, Victoria-street, S.W., Sept. 15, 1893.

BRADFORD CORPORATION ELECTRICITY SUPPLY.

This electric installation, which was inaugurated on September 20, 1889, is on the "continuous" current system, and it is intended for a supply at "low pressure" for lighting, motive power, storage, and other applications, both industrial and domestic. The district at present supplied is situate in the centre of the town, and it comprises those streets which contain the best shops, as well as a few hotels, the Town Hall, and the public markets. The central generating station at Bolton road is at the eastern edge of the above district. The buildings erected there will, when completed, contain considerably more generating plant than is there at present. This plant now consists of four steel boilers of the "Lancashire" type, each 28ft. long by 7ft. in diameter, and one Babcock and Wilcox tubulous boiler of somewhat less capacity than each of the above boilers. The steam engines—compound, non condensing—are of the inverted vertical type, each driving direct, and placed on the same bed plate with a Siemens dynamo; and they have a total output of 1,200 h.p. indicated. All of the steam engines (except one, a Marshall double acting one) are of the Willans single acting type. The total current output of the dynamos is 5,000 amperes, which is delivered throughout the district of supply at a uniform electrical pressure of 115 volts. To the above generating plant there is added a Crompton Howell secondary battery of 70 cells, and having a storage capacity of 1,000 ampere hours. This battery plays a most important part in the working of the station, both electrically and financially, inasmuch as it enables the steam engines and dynamos to be stopped, on an average, from 10 to 12 hours daily; furthermore, whilst the engines are running, it acts as a regulator, counteracting the disturbing effect of any sudden demands, or of the contrary, upon the supply. Electrical instruments, and other apparatus, for the control and measurement of the supply to the town are also fitted up at the central station.

The supply of electrical energy is carried into the town and distributed to the houses at "low pressure" by means of underground armoured cables, which are laid in the ground itself, without the intervention of any culvert, and in most cases under the footpath on each side of the street. The mains—both the feeders and the network for distribution to the houses—have been laid on what is termed the "two-wire" system; owing to its being simpler in working at the commencement, before a supply is thoroughly established. Provision was, however, made at the very outset to enable (later

on, when the increasing demands for the supply should require it) the arrangements commonly known as the "three-wire," the "five-wire," or other even higher pressure being adopted. The demand for the supply has been very steadily increasing throughout the four years that the installation has been in operation. The series of half yearly accounts hereto annexed prove this, and point to the financial success which has attended this industrial enterprise. So large has been the augmented custom that for some time all the resources of the installation have been at times very severely taxed, and notably in the arrangements for the distribution of the supply in the town. The time had evidently arrived to take advantage of the provision made for the adoption of the "three-wire," the "five wire," or some other arrangement, such as would ensure for some years, at least, largely augmented facilities for coping with the growing demands, not merely as regards lighting, but also for motive power, and other industrial and domestic applications. The Corporation, recognising the importance of the step about to be taken, and the very considerable influence it would have upon the future development of the electrical supply in their town, and in the immediate vicinity, resolved, before deciding upon any definite proposal, to obtain the highest scientific opinion available, not merely as to the extensions which might be required, but also as to the correctness, or otherwise, of the system which had, so far, been adopted. Lord Kelvin, P.R.S. (better known as Sir W. Thomson), was good enough to undertake the task. He advised the adoption for the centre of the town of the three wire, while reserving the five wire, for a future period, in the more distant parts. At an interview with the Corporation on July 19th last, in Bradford, his lordship, after having carefully inspected the present works, in reply to various questions from the members of the Electricity Committee, said that: "The committee had acted rightly in adopting the present system at the commencement of their undertaking. The possibility of adopting the three wire system at a future time was fully considered when the works were at first laid down. The three-wire system would at that time have been premature, with the comparatively small demand for the electric light then to be provided for. . . . Replying to a question from the chairman, as to the use of the 'continuous' or of the 'alternating' current with the three wire system, Lord Kelvin said: 'Continuous current was undoubtedly preferable, even in high tension (say 2,000 volts). . . . Alternating currents were a success when a transformer was in use at each separate premises, but the use of transformers involved difficulties which did not arise with continuous current. The latter is better where there are varied requirements, as for charging accumulators, driving motors, electro plating, etc. The alternating current is more difficult to transmit in large quantity than continuous current. Alternating motors were not yet well adapted for practical use.'"

The following letter has been sent to Mr. Shoolbred from the Town Clerk's Office, Town Hall, Bradford, dated 12th August, 1893:

My Dear Sir,—I congratulate you on the fact that Lord Kelvin has done you ample justice as to your electric installation here. It justifies what you have done, and adds, that if we were to begin again it would be our duty to repeat the operation; and further, that the two wire system was the right thing at the time, not only *per se*, but as being capable of having three wire or five wire system applied, if found to be advantageous.—Yours faithfully,

(Signed) W. T. McGowen.

ELECTRIC LIGHTING AT EDINBURGH.

In our last issue reference was made to a report prepared by Prof Kennedy on the electric lighting of Edinburgh. We now give the report as follows:

On April 8 last I had the honour of making a preliminary report to the Electric Lighting Committee of the Town Council, and during the following month I received instructions from the town clerk to draw up a complete scheme for the lighting of the city. I have since then spent some time in Edinburgh, and have gone very thoroughly into the whole matter, and have pleasure in now presenting the following report.

So far as the figures in my preliminary report are concerned, I may say at once that further investigation has substantially corroborated them throughout, and I have not, therefore, anything to modify in what I originally stated, except that I find the total cost will be somewhat less than I had estimated it, although I have provided for slightly increased plant.

The first question which I had to examine was that of the area to be lighted. The district in which I advise that mains should be laid covers practically the whole business part of the city, from the Register House to Donaldson's Hospital, and the principal residential streets and terraces, along with as much of the business part on the south side as has been scheduled in the Act, with the addition of Cockburn-street and a part of High-street. I should not have included the streets nearest the University Buildings at present, but have no alternative, as they are among those scheduled in the Act.

The extent of the public or street lighting is a matter which must essentially be left for the decision of the Town Council. I understand that it is decided that the principal streets should be lit by arc lamps. This includes Princes-street and George-street, with the connecting streets between them, Leith street and the bridges, as far south as the limits of the scheduled district, High-street up to George IV. Bridge, Bank street, the Waverley Bridge, and the Mound. The lighting of the streets would involve the use of about 130 arc lamps and the cost of these lamps, with the lampposts, cables, and road work, and all necessary plant in the station for supplying current to them is included in my estimate.

The determination of the best system to be adopted is, of course, the matter which has taken up the greater part of my attention. The question is, in almost all cases, a difficult and complicated one, and Edinburgh has been no exception to this rule. The actual electric light as given out by incandescent lamps is absolutely the same, and equally good, by whatever system generated. There are, or may be, differences between the different systems in capital cost, in cost of production, and in general convenience of application and ease of regulation, but not in quality of light. Bearing these points in mind I have found it necessary to make detailed estimates of several different schemes for lighting the city by different systems, and my recommendation is the result of a comparison of these. In regard to the two principal points—namely, the double requirement of minimum initial cost, coupled with minimum cost of working—it may, of course, happen that both these minima cannot be reached by the same system in any given place, and in that case the one has to be balanced against the other. But in addition to these obvious considerations, I have had to bear in mind two other very important ones—namely, (1) that, if possible, the system used should be such that one central station should serve for the whole of the city for at least a long time to come; and (2) that it should be such that very large extensions can be made as required without going beyond the original lines, and without unreasonable additional cost.

From this point of view I found it necessary to compare the possible future demand in the south of Edinburgh with that probable in the northern district now to be supplied. I have no doubt that a demand will grow up in the southern district. If this district had been at all likely to yield as large an income as the northern district, it would probably have been worth while to put down a special station for it, in spite of the inevitable drawbacks of having more than one central station. I find, however, from a careful examination of the number of houses and length of streets in it, that it will require about twice the length of mains to supply it that is required by the northern district, and that at the same time it can never be expected to yield much more than a quarter the income of the northern district. The cause of this is, of course, the fact that it is mainly a residential district, and, further, that its houses are somewhat widely separated from each other, instead of being built in compact terraces. Under these conditions, it becomes specially important that a second station should not have to be built for this district, as such a station would be so much smaller and so very much less profitable than the northern one. These circumstances have decided me to recommend to you a plan by which both districts should be supplied, as time went on, from the one station.

For a compact urban district like northern Edinburgh, in which the lighting will be very heavy, there are practically four possible systems, with various modifications. These are (1) A three wire system, something like that which I have used in Glasgow; (2) a five wire system, such as that which is about to be started in Manchester; (3) some modification of the "Oxford" system; and (4) a combined high and low tension system, such as that used by the City of London Company. I have, after consideration dismissed the five wire system and the Oxford system as being unsuitable under the circumstances, and have worked out in detail only the other two. I have proceeded on the assumption that the central station should supply current sufficient to keep 20,000 lamps of 8 c.p. alight at one time, which is probably equivalent to about 40,000 lamps actually installed. This is the figure which I gave in my preliminary report. For this purpose the station should contain (whatever the system used) engines of about 1,500 i.h.p. (including reserves), with the corresponding dynamos or alternators and boilers, etc. With a three wire system there would be heavy trunk mains acting as feeders, and delivering current to the distributing network at various points throughout the town at a pressure of about 220 volts, but there would be no machinery or apparatus of any kind beyond the walls of the central station. With the high tension system the current would be delivered from the station at about 2,500 volts and carried by small high tension feeders into some six or eight transformer sub stations, placed in cellars or other suitable positions throughout the district. In these sub-stations there would be placed the necessary transformers and other apparatus for redistributing the current by low-tension sub feeders into the network at 220 volts.

The total cost of the plant in the central station, and the space taken up by it, I find to be practically the same in both cases. The cost of the distributing mains is also practically the same in both cases. The cost of the low tension feeders also work out the same as the total cost of the combined high and low tension feeders, the transformer sub-stations and the transformers themselves, with their instruments and connections. The total cost in each case, including an allowance of £10,000 for buildings, and including also the arc lighting plant, but not including the cost of land, will be about £80,000, or £5,000 less than the sum stated in my original estimate. The cost of doubling the capacity of the plant and mains, when this should become necessary, would be about £30,000 in the first case, and about £28,000 in the other. There is thus no practical difference in capital cost between the two systems, and so far as expense goes the decision as to which is best in this case must depend on the cost of working them. The working costs for a three wire system are well known, as many are in operation. The cost of working a combined high and low tension system can hardly yet be said to be known,

as no system of this kind has been at work anywhere for a sufficient length of time. It has, unavoidably, the considerable additional annual expense of the rents of the transformer sub-stations and the wages of the men employed to attend to them, and, including this, the lowest estimate which I can make of the difference in cost of production between the two systems is 0·5d. per unit on 680,000 units per annum; the difference might well be much greater. The balance of advantages, therefore, seems to me very much in favour of the use of a three-wire system for the northern district, and I recommend the adoption of this system.

In the southern district—for, as I have already said, I consider myself bound to consider this district as well as the other, in order that you may not be saddled with arrangements which shall prove unsuitable in the future, however advantageous for the present—the balance of advantages is altogether altered. The average length of feeders, which in the northern district is about three quarters of a mile, would be more than doubled, and the heaviest consumption would be at the ends of the longest feeders. In many places, too, the houses are so far apart that the cost of low tension distributing mains would be disproportionate to the income likely to be derived from them. These conditions are just those in which the advantages of an alternating current system make themselves felt. Not only is the additional outlay caused by the increased length of feeders much less than with low tension, but it is also possible to supply current to scattered terraces and isolated houses with transformers in the separate houses, at the same time using special transformers with low tension distributing mains wherever the demand for current justifies this. I think, therefore, that in supplying the southern district it will be advisable to use an alternating current high tension system (at not less than 2,500 volts), laying down low tension network wherever it may be found worth while to do so.

The local conditions which I have briefly summarised above therefore indicate that a low tension system should be adopted at once for the northern part of the city, and a high tension system for the southern part when it has to be supplied, and for any other isolated or outlying parts, such as the terraces on the Calton Hill. I have already said that I thought the whole city should be supplied from one station, at least until the demand was very much greater than anything at present contemplated.

There are, of course, certain obvious inconveniences in the use of two systems from one station, but these exist much more in imagination than in reality. The boilers, steam pipes, pumps, and buildings would be the same for all the plant, and there is no reason why the same type of engine, at any rate, should not be used throughout. Practically, the double system involves merely the use of electrical machines and switchboards of two different types in the same station, and I see nothing in this which is sufficient to justify me in rejecting, for either district, the plan of supplying it with electrical energy which appears undoubtedly the best for it. I recommend, therefore, that the central station should be so arranged that extensions for the lighting of the southern half of Edinburgh, when this is required, can be made on an alternating current system such as I have mentioned.

If the station were to be entirely a continuous-current station, I should have recommended that series arc lighting machines, of the usual construction, driven by separate engines, should be used for the street lighting, as has been done in Glasgow. As, however, there will in any case no doubt be alternators in the station before long, I recommend that two alternators be put down at once and used for arc lighting by the employment of Mr. Ferranti's constant-current commutators. So far as I have seen this apparatus it seems to be successful for the purpose of supplying a current suitable for the working of arc lamps in series, and its use with alternators will have the enormous economic advantage that special plant will not be required for the arc lighting, which can be worked from the ordinary switchboard used for the alternating currents.

When working out the scheme which I have described, I found that it would have been both convenient and economical to use one or more sub-stations containing gas engines driving dynamos. Such stations would entail very little additional expense in the way of attendance, as they would only be worked during the hours of maximum load, and then only during part of the year. They would also have allowed the cost of the mains to be considerably reduced. I regret, however, that the final decision of the Gas Commissioners, of which a copy has been sent to me, appears to render it impossible for any scheme of this kind to be carried out economically.

In my preliminary report I stated that the total works cost, including office expenses, should be about 3d. per unit when your output reaches 300,000 units per annum, and 2·5d. per unit when it is 680,000 units per annum. The interest and sinking fund on £100,000, if taken at 5 per cent., amount to 4d. and 1·75d. per unit respectively, making the total costs 7d. and 4·25d. per unit for the two outputs. It cannot be expected that the station should pay its way during its first year of working, but where so large a portion of the cost is a fixed charge it is, of course, of the greatest importance to do everything to secure the largest possible output at the earliest possible time. From this point of view I believe it would be the best and safest policy to start at once with a charge of 6d. per unit, the charge which is now made over nearly the whole of London. In this estimate of output and cost I have, as before, omitted the arc lights entirely, as I presume that the street lighting will be carried out for yourselves at cost price. The rate paid by the Corporation of the City of London is £27 per annum for each arc lamp, including trimming and the supply of carbons; no doubt it might cost you somewhat less.

Prof. Kennedy concludes by giving a list of streets, etc., in *which it is proposed to lay distributing mains.*

BUSINESS NOTES.

Capetown.—Telegraphic communication has been restored between Capetown and Victoria.

Paignton.—An electrical firm has written to the Local Board offering to light the town by electricity.

Western and Brazilian Telegraph Company.—The receipts for the week ended September 22 were £3,223.

West Ham.—The Town Council has deferred the consideration of the question of electric lighting for six months.

Clerkenwell.—The Vestry have declined to grant an extension of time for the completion of the electric light station.

Gravesend.—The Mayor has interviewed the Postmaster with a view to an all night telegraphic service being instituted.

Cuba Submarine Telegraph Company.—The receipts for the month of September were £295 less than for the corresponding period.

Direct Spanish Telegraph Company.—The receipts for the month of September were £146 less than for the corresponding period.

Eastern Telegraph Company.—The receipts for the month of September were £55,567, as against £55,710 for the corresponding period.

Northampton.—The surveyor to the County Council reported last week that the putting in of the electric light in the judges' lodgings had cost £260.

Bayswater.—The Wesleyan chapel has been electrically equipped by Messrs. Money and Nash, there being 73 incandescent lamps installed.

Plant Wanted.—The Northern Co-operative Company, of 54, Loch-street, Aberdeen, require offers for supplying boiler, engine, dynamo, and other electrical plant.

Situation Vacant.—An electrical engineer is required for the training ship "Shaftesbury," off Grays, Essex. Particulars will be found in our advertisement columns.

Tenders Required.—The Rivers Committee of the city of Manchester, as will be seen from our advertisement columns, invite tenders for the supply and fixing of electrical plant.

Islington.—Mr. Albert Gay informs us that he is no longer connected with the House-to-House Company, having been appointed electrical engineer to the Vestry of St. Mary, Islington, N.

Wandsworth.—The Vestry have granted an extension of six months for the County of London Electric Light Company to comply with the seventh section of the provisional order issued to them.

Henley's Telegraph Works Company, Limited.—We understand that dividend warrants have been posted for the half-yearly interim dividend on the preference shares at the rate of 7 per cent. per annum.

Fulham.—The question of providing a telephone for the Vestry has been referred to the Town Hall Committee for consideration. The Vestry are enquiring about the position of other local authorities as regards electric lighting.

Haslingden.—The Board of Guardians have authorised the chairman to sign a petition which is to be presented to the Corporation of Rawtenstall, requesting that the fire-engine station be connected with the National Telephone system.

Willenhall.—The Local Board have instructed the clerk to make enquiries as to whether the authorities would connect Willenhall by telephone with Wolverhampton and Walsall, in order that the brigades might be summoned in case of a fire occurring.

Appointment.—Mr. Lee has been appointed engineer to the Southampton Electric Light and Power Company in the place of Mr. R. A. Scott Moncrieff, who has left to join Messrs. Kilburn and Co., the Calcutta agents for Messrs. Crompton and Co., Limited.

Shoreditch.—The Electric Lighting Committee of the Vestry have requested Messrs. Manlove, Alliott, and Co. to report for £10. 10s. on the cost of burning 20,000 tons of dust per annum, with a view to the resulting heat being utilised for electric lighting purposes.

A Large Blast.—A huge mass of rock has been blasted at the Dinorwic Quarries at Llanberis. All the preparations for the great blast were carried on by the aid of the electric light, an installation being erected on the spot by the British Electric Light Company.

City and South London Railway Company.—The receipts for the week ending October 1 were £795, against £786 for the same period last year, or an increase of £9. The total receipts for the second half year of 1893 show an increase of £455 over those for the corresponding period of 1892.

Telegraphy.—An agreement has been signed whereby telegraphic communication is to be established between Llandyssul and Llangranog. Operations will commence in the spring. It has also been decided to establish telegraphic communication between Llandyssul and Velindre, Llangeler, Carmarthenshire.

Bank Lighting.—The new buildings of the London and Midland Bank at Bradford have been equipped with the electric light, there being installed 45 16-c.p. lamps. The installation has been put up by Messrs. Rosling and Matthews, of Bradford, and the fittings have been made and supplied by Messrs. Hunt, of Birmingham.

Brazilian Submarine Telegraph.—The Directors of this Company recommend a final dividend of 3s. per share, making 6 per

cent. for the year ended June 30, and a bonus of 1s. per share (both tax free), leaving a balance of £10 533, out of which £7,000 has been placed to reserve, increasing that fund to £638,075, and £3,533 being carried forward.

York The Technical Instruction and Public Library Committee of the Town Council have agreed to the lighting of the institute building by electricity, and they ask the sanction of the Council to the acceptance of the tender of Messrs. Benson and Co., of London for carrying out the wiring of the building in connection therewith for the sum of £314.

Paddington. -- The Paddington Baths Commissioners have decided to place two electric lights of 52 c.p. in front of the baths. This is a modification of the specification of the contract, and the mover of the proposal at a meeting of the Commissioners said he was sure that Messrs Dawson and Hammond, the contractors, who were obliging people, would consent.

Canterbury.—The following report of the Electric Lighting Committee was adopted at a meeting of the Town Council last week "The committee recommend that a letter be written to the Board of Trade stating that the Council are perfectly satisfied with the steps the Canterbury Electricity Supply Company, Limited, are taking to carry out their agreement with the Council."

Tweedmouth. –The sawmills of Messrs. Allan Bros. have been fitted throughout with the electric light A Parsons steam turbine and dynamo of 25 h p. supplies the electrical energy, and altogether in the various shops and offices there are nearly 200 incandescent lights. The installation, which is the first of the kind in the Berwick district, has been carried out by Messrs. A. A. C. Swinton and Co.

Picture-Lighting. The contract for the electric lighting in connection with Messrs Agnew and Son's picture gallery in Manchester has been given to Messrs Drake and Gorham, whose Manchester branch is carrying out the work. There will be about 100 lights, and a special feature in this case will be the reflectors, the contractors taking pains to obtain the best possible effect. Mr. Walter Leake is the consulting engineer.

Lewisham -The Board of Guardians have conferred with their architect, Mr Harston, as to the lighting of the new infirmary. Mr Harston estimated the cost of installing the electric light at £5 000, and put the cost of its maintenance at about the same, or, perhaps, a rather higher figure than for gas, which he calculated to amount to £250 per annum for lighting purposes apart from cooking. It was decided to light the infirmary by gas.

Morley The Corporation are prepared to receive particulars of schemes for the electric lighting of the Town Hall and the borough generally. A premium of £100 will be awarded to the scheme selected by the Council as the most suitable for the requirements of the borough. Plans and particulars are to be sent before 1st of December A copy of the conditions of the competition will be forwarded on application to Mr. R Borrough Hopkins town clerk.

Pontypool.—The clerk to the Local Board read a letter last week from Mr W. Pegler suggesting that the Board should have electric lamps fixed in prominent places in the town, the cost of which, he thought, would be about £15 each, exclusive of fixing A discussion ensued, at the close of which the matter was postponed for a month. The Chairman remarked that he did not think they could use electric lamps without the consent of the gas and water company.

Electric Lighting of Derby. –The central station is now practically complete, and will be formally started next Tuesday The occasion is to be celebrated by a banquet at the Royal Hotel, given by the Mayor (Mr Councillor Marsden, J P.). Previous to the banquet the Mayor and Corporation will proceed to the electric lighting station in Full street, where the ceremony of starting the station will be performed by Mr. Marsden A managing engineer has not yet been appointed.

Kingston-on-Thames.—The Corporation invite tenders for the electric lighting of the Town Hall, public offices, library and courts. Specifications and forms of tender may be obtained at the town clerk's office, Clattern House, Kingston upon Thames, where plans may be seen, on payment of £1. 1s., returnable on receipt of a *bona fide* tender. Sealed tenders, endorsed "Public Buildings Electric Lighting, must be delivered at the office not latter than to-morrow, the 7th inst.

Dudley. Alderman Bagott mentioned at a meeting of the Town Council on Tuesday last that recently a local manufacturer had introduced the electric light, and he thought that it might be an incentive to the Council to go more thoroughly into the matter of providing the town with a similar light. They were obtaining all information they possibly could in order to introduce a competitive light, and they hoped to be prepared shortly to give the Council some useful particulars in regard to the matter.

Taunton.—A special meeting of the Town Council was held on Monday to receive and consider a report of the Electric Light Committee, to affix the seal of the borough to the contract with the electric light company for the purchase of the works, and to make arrangements with respect to the new loans The committee reported further that they had had an interview with Dr Fleming, who would report fully on various subjects when he had considered the information which he had obtained from the officials. The recommendations of the committee were adopted.

West Calder The ceremony of turning on the electric light took place recently in the premises of the local co operative society. The society's plant, which has been in use for the past four years, is now enlarged so as to form a central station for the distribution of the light throughout the district. A large dynamo of the Elwell Parker type is used during the day to transmit power by overhead wires to motors, which in turn drive machinery belonging to the society, and in the evening the whole of the society's premises are lighted with arc and incandescent lamps.

Lighting at Lambeth The question of lighting the workhouse by electricity was again considered at a meeting of the Board of Guardians last week. In addition to the scheme propounded by Mr. Preece, that gentleman now estimated that four boilers, costing £1,600, would be required for electric and other purposes At the previous ordinary meeting of the Board Mr Lake moved that no further action be taken. Upon resuming the consideration of this motion last week the chairman put it to the Board, and it was carried without discussion.

Ipswich. -At a meeting of the Paving and Lighting Committee of the Town Council last week, the chairman said that the subcommittee as to electric lighting had arrived at the conclusion that it would be unadvisable to take any step to apply for a provisional order in the next session of Parliament, and therefore it would be well to let the matter stand over for a few months. In the early part of next year they would recommend that a report should be made to the Council, and that would involve the necessity of appointing some skilled person to advise them.

Great Missenden A meeting was recently held to further consider whether the Lighting Act should be adopted in the district comprising the village only, and also to consider a proposition of the British Volta Electric Glow Lamp Company, to provide all the plant and fittings at their own cost, and also to provide 13 electric lights each night, from September to March, for all hours from one hour after sunset to 10 15 p m., on condition that the charge to the village shall not exceed £15 per year. There was a large attendance, and it was resolved to accept the proposition of the company.

Leamington. The Vicar proposed at a meeting of the Vestry last week that the parish church should be lighted by electricity. There were many complaints about the lighting at present, and a generous parishioner had offered to advance a loan of £250, free of interest, for the purpose of covering the expenses of the installation. He proposed that the offer be accepted, and the work proceeded with Mr H Ford seconded the resolution. Mr. Whitehouse stated that the electric lighting company offered terms which would make the cost a very little more than that for gas The resolution was carried.

Worcester. At the meeting of the Board of Guardians the Building Committee recommended that instructions should be given to obtain as many gas brackets as might be required for the basement of the new workhouse Mr Winwood complained that these were not provided for in the estimate, and said that everything was done, by under estimating the gas required to curtail the expense, and to run up the estimated cost of electric lighting by including everything. Mr Edmonds said that it would be found in the end that the gas would not cost more than what was estimated. The recommendation was adopted.

Portishead In reply to an advertisement for lighting tenders, three tenders have been received by the Local Board for doing the work by electricity, by oil, and by gas. The electrical tender suggested the purchase of plant to the amount of £12,460. The oil tender was said to work out to £2 4s 6d per lamp. The offer of the Portishead Gas Company was £2. 2s. per lamp. Mr. Davis said at a meeting of the Board last week that he thought they would before long see electricity introduced Keynsham was wonderfully pleased with its electric light, and it cost less than the lighting at Portishead, where gas was used. It was resolved to accept the tender of the gas company.

Folkestone - The Mayor mentioned at a meeting of the Town Council last week that they had received a letter from Mr. Mark Parker, the gentleman who reported on the electric lighting, asking for a cheque The sum which they had agreed to pay him was 50 guineas, and he should therefore ask that this sum be added to the account for which cheques were to be drawn. Councillor Penfold moved, and Councillor Thompson seconded, that the money be paid, and a cheque was drawn for the amount. At the same meeting Councillor Thompson said with regard to the difficulty of lighting, that would all be obviated in a few months, when they had a new element for lighting.

Liverpool Overhead Railway.—The directors of the Liverpool Overhead Railway Company have this week invited subscriptions for 2,500 perpetual preference shares of £10 each, bearing a preferential dividend of £5 per cent. per annum. This issue is in addition to £75 000 in preference shares already issued out of an authorised £120,000, the Company's remaining authorised capital being £450 000 in ordinary shares, of which £375,000 have been issued, and £190,000 in debentures, £125,000 of which have been issued. The additional capital is required to complete and equip the northern extension of the railway to Crosby road South, Seaforth, authorised by the Act of 1892, and to provide additional rolling stock and new stations.

Sunderland. The question of electric lighting was considered by the Highways Committee of the Corporation last week, when a report by Prof Kennedy on the scheme of the electric lighting of some of the principal streets of Sunderland was presented The report suggested specifications for plant, and sets of plans of the work. There are 10 sets of plans, and the Committee decided to obtain 20 copies of each at a cost of £20 They also decided to have complete specifications made out in accordance with Prof. Kennedy's suggestions, and also to advertise for tenders from electrical engineers supplying and fixing the plant The Dunning street hospital is intended to be used as the station from which the electric supply will be worked.

Wrexham.—When the Town Council assembled last week the Clerk said that after the special Council meeting when it was decided to offer the Wrexham Electric Company £250 for their provisional order he wrote to the Corporation's parliamentary agents concerning the matter. He did not wish any debate to arise, and only read the letter as a matter of information. The agents stated that the proposal was without precedent and that the purchase could only take place subject to the approval of the Board of Trade and the Local Government Board. He would, now the minutes of the Council meeting had been confirmed, write to Messrs Lewis and Son making the offer subject to the approval of the authorities mentioned.

Glasgow.—Plans and specifications are in course of preparation for lighting by electricity the compulsory area, as well as a certain area beyond it. Electricity as an illuminant is being largely adopted in the warehouses and shops, and soon the Corporation will have to increase the generating plant. In Mr Anderson's Polytechnic, Argyle street, an installation of the Crompton lamp has been completed. By means of 30 of these lights, each of 1,000 c p., two of the principal floors have been lighted with satisfactory effect. By an arrangement of the lamps the dark shadow usually thrown by the arc light has been avoided, and so nearly does the light resemble ordinary daylight that the natural colours of the fabrics are in no way altered to the eye.

Leicester.—On the presentation to the Town Council last week of the half yearly report of the Gas Committee, it was mentioned that the Local Government Board had approved of the scheme for electric lighting. Alderman Lennard moved "that so much of the report as relates to electric lighting be approved, and that the Gas Committee be authorised and directed to at once proceed with the arrangements necessary for carrying out the scheme which has already been approved by the Council." He remarked that the matter had been about longer than they desired. But the Local Government Board had now sanctioned the loan of £50,000, and the work would be proceeded with without unnecessary delay. Councillor Billings seconded, and it was agreed to.

An Amalgamation.—We understand that negotiations have been for some little time in hand, and are now almost completed, for the amalgamation of the Acme Electric Works, in Ferdinand-street, Chalk Farm, N W, with the Malden crescent works of the General Electric Power and Traction Company, Limited, the two factories, joined together under one management, being intended to form a London works for the Electric Construction Company, Limited, where may be manufactured the lighter and smaller electrical appliances required by the latter in its central station and traction work, leaving the dynamos, motors, and other heavy details to be made at Wolverhampton, and storage batteries at Millwall. The combination ought to be very advantageous to all concerned.

Electric Regulating Clocks.—A company established at 39, Victoria street, Westminster, and bearing the somewhat pretentious name of "The Industrial and Mercantile Investment Corporation, Limited," is introducing into this country a system of electric clocks which has for some time been very successfully operated in Brussels and other important centres on the Continent. In this arrangement a master clock sends a momentary current from a few Leclanché cells every half minute over a circuit in which are inserted a number of magnets each actuating a dial through simple mechanism. The system is practically similar to some already promoted for the self winding and synchronising of clocks, but has the advantages of greater simplicity and cheapness to recommend it.

Perth.—At a meeting on May 1 the County Council appointed a sub committee to "enquire as to the best method of establishing telephonic communication between the various county and district officials, including the chief constable and members of constabulary throughout the county, and that the Standing Joint Committee be asked by this meeting to co-operate with the sub committee in their investigations" Both the National Telephone Company and the Post Office had been approached regarding terms, but the rentals quoted were so high as to be quite prohibitive. The sub committee report that there was little hope of being able to establish telephonic communication for county purposes until the trunk system was extended over the county generally. They, however, agree in expressing the opinion that such communication should be taken advantage of for the police and county officials as soon as it can be got on reasonable terms.

Kendal. When the Rural Sanitary Authority met last week to consider a resolution to take steps to promote a Bill for the transference of the gas and water supply to the Corporation, Mr Monkhouse said that some objectors talked about the electric light, and that he had once thought that it might be introduced into Kendal, but when it was considered by a committee it was found the expense would be such that they could not recommend it. The electric light as a lighting medium was a very long way from Kendal, and even in large places it was found that they could not supply it for anything like the price of gas. Kendal was not an advancing town, and its tradesmen were not like those of London, Manchester, and other large places where they wanted plenty of light, and could afford to pay for it. And supposing they had it, there was no town that he was aware of where their running it had ever interfered with the output of gas.

Lighting at Dublin.—A report concerning extensions has been issued by the Electric Lighting Committee of the Dublin Corporation. The committee have already spent £38,408 on account of a sanctioned loan of only £37,000, and they propose to take an additional sum of £24,348, of which £13,000 has been already authorized *by the Municipal* Council. The increase of new business is the reason for the extra outlay. The report contains statements of accounts regarding the working of the station for the two quarters from September to March. The total revenue amounted to £4,245, of which private consumers contributed £2,496 The working expenses, after deducting £248 for carbons and other stores in hand, were £376, thus leaving a balance to be carried to the net revenue account of £869. This credit is changed into a debit of £194 by the payments of interest and redemption to the Commissioners of Public Works and of the interest on the bank overdraft.

A "Revolving Reaction Engine."—What is termed a "revolving reaction engine" has been devised by Mr A Morton of Glasgow. One of two engines completed has been tested by Prof Barr and Mr Henry A Mavor. The engines have been erected in the works of Messrs Campbell, Smart, and Co., Old Dumbarton road. One is connected direct with a large Schiele fan and the other with a high speed dynamo The former runs at about 1,200 and the latter at about 4,000 revolutions per minute. The engine and dynamo are bolted on the same bed plate and the dynamo is connected with a series of incandescent lamps to act as an electric brake to the engine In the circuit there are Cardew and other voltmeters, and also ammeters. It is this engine that has been reported on by Prof. Barr and Mr. Mavor In their report they say. "The results here reported seem to indicate that considerable improvement may be expected from higher speed and better vacuum, and further experiments in the direction of still further developing the ideas embodied in the present form of engine are likely to result in greatly improved economy."

Battersea Polytechnic.—By the end of this year Battersea will be in possession of a fine polytechnic institute. It stands just on the verge of Battersea Park The building is enriched by 10 statues representing respectively Architecture, Sculpture, Painting, Engraving, Music, Poetry, Chemistry, Electricity, Mathematics, and Engineering. On the right of the entrance hall, passing into the building, is the administrative department—enquiry office, secretary's office, council room, clerks' room, and stores and a first-rate electrical laboratory. There is on the ground floor an engine room, fitted with Robey compound engines of about 120 h.p. These engines are necessary, from the fact that mechanical and electrical engineering are to be among the chief subjects of technical instruction here, as they are among the principal industries of the district of London. Besides these steam engines, there is a 12 h p. gas engine, which will be employed in driving two dynamos, with a capacity for supplying 1,100 lights about the institute. This electrical installation has been entrusted to Messrs. J. G. Statter and Co., of Victoria street, Westminster.

Killarney.—A meeting of the Town Commissioners was to have been held on Monday, but a quorum not having attended, no business was transacted. Monday was the day for holding the monthly meeting, and various important matters would come on, including the public lighting question. At present there is a strong rivalry between the gas lessees and the electric light company on the public lighting question. Not long since the gas lessees and the electric light company tendered for the lighting of the town, the former at £92 10s., and the latter at £50 The majority of the Commissioners present at the meeting—at least of the Commissioners who voted appeared to have given the contract to the gas people, notwithstanding the difference between the tenders. The electric light people allege informality, and served a notice on the town clerk and the Commissioners' solicitor, cautioning them not to perfect the contract for the gas. They also served notices on Mr. Leonard and the chairman from voting on the lighting question, they being shareholders in the gas company. Since the service of these notices the Commissioners who are the avowed supporters of gas have not attended a meeting, and, it is said, are not likely to until the matter is settled one way or another.

Camberwell.—The Vestry had placed before them last week by Mr. Wallace a report from Mr. Manville with reference to a scheme for the introduction of the electric light in the parish. Mr. Manville pointed out in his report the steps that would be necessary to be taken by the Vestry should they desire to apply for a provisional order, the estimated cost of which would be about £800. With regard to this, action must be taken almost immediately. A committee of the Vestry specially pointed out that part of Mr. Manville's report dealing with the utilisation of the ashbin refuse for the production of the electrical energy required. They recommended: "(a) That the Vestry consider the report of Mr Manville, and fix a time for a public lecture by that gentleman; and (b) that should the Vestry desire to proceed further in this matter, a joint committee of 24 members be appointed, consisting of an equal number of members from the following four standing committees—viz., the General Purposes, Sewers and Sanitary, Finance, and Plant and Scavenging—to report further thereon, and recommend to the Vestry" After some discussion it was decided to make arrangements with Mr. Manville to give a lecture as early as possible, any further step to be a matter of future consideration.

Hanley.—The Electric Lighting Sub Committee of the Town Council recommended on Wednesday that the committee should be empowered to obtain separate tenders for the electric light wiring and fittings required in all the buildings of the Corporation, and to make application to the Local Government Board for permission to borrow the money required for such work. The borough surveyor having reported that it was desirable to exercise the option provided in the contract entered into with the Brush Electrical Engineering Company for the Corporation to determine whether the company should provide the fourth set of generating plant—viz., boiler, engine, and dynamo—at a cost of £1,800, or

expend that amount in electric light street mains and appurtenances, the sub-committee recommended that the Council should give notice to the Brush Company of their intention to require the amount specified to be expended on street mains, etc., instead of generating plant, and that the borough surveyor be instructed to submit plans for the proposed mains. Mr. T. W. Harrison moved the confirmation of the minutes, remarking that the installation of the electric light was progressing, and he believed that they would be able to supply the light within the next few months. After a brief discussion, the motion was carried.

Loans for Electric Lighting.—The Finance Committee of the London Council on Tuesday reported as follows: "We have to report that we have been in communication with the Lords Commissioners of Her Majesty's Treasury with reference to the period over which loans for electric lighting purposes should be spread, and have now received a reply, dated July 29, 1893, in which their lordships accept the view urged upon their consideration with regard to the absolute necessity of all appliances and work in connection with electric lighting being kept in a thoroughly efficient condition to perform its work and the assurance that the Council would be advised by its professional officers on every application for a loan for electric lighting purposes, so that if any considerable portion of a loan was for short-lived purposes the term for that portion would be considered, and the circumstances of each case taken into account. Subject to these observations, the Treasury agree that in the case of loans of this class the whole initial cost may be taken into account in fixing the period of repayment, and that repayment may be spread over such period of years, not exceeding 30, as may seem appropriate in each case. We are glad that the Treasury has seen its way to agree to the request of the committee, as we consider that it will give increased facilities to the vestries and district boards in introducing electric lighting in their districts."

Lighting at Bolton.—The Gas Committee of the Corporation met on the 29th ult., when the proceedings of the Electricity Sub-Committee, which included tenders for the supply of transformers and underground cables, were considered. The tender of Messrs. Siemens Bros., Limited, for the supply of high tension and low tension cables was accepted, as was also that of the Brush Electrical Engineering Company for the supply of transformers. A letter was read from Mr. W. Kearns making application to be allowed to withdraw from his contract for excavation work in connection with the new electricity undertaking. Mr. Kearns attended and explained the reasons for his application. Mr. George Goodlad attended and submitted a tender for the excavation, concreting, and other work required in the erection of the generating station in place of Mr. Kearns, at the price named in Mr. Kearns's tender. The committee agreed to accept Mr. Goodlad's tender, and agreed to discharge Mr. Kearns from his contract conditionally upon Mr. Goodlad entering into a contract in writing, to be prepared by the town clerk, to provide sufficient sureties for the due carrying out of the work. The tender of the Stanley Coal and Iron Company for the supply of cast iron pipes for the cables was accepted. Mr. D. Lee was appointed clerk of the works for the supervision of the erection of the new buildings at the generating station.

Electric Pumping Plant.—We understand that Messrs. Ernest Scott and Mountain, of Newcastle-on-Tyne, have contracted with the Lothian Coal Company, Newbattle Collieries, Dalkeith, near Edinburgh, for the supply of two electric pumping plants. The plant will consist of two compound horizontal condensing engines, each engine to be capable of giving 120 effective horse-power. The engines will actuate a main countershaft driving on to two "Tyne" dynamos, each capable of giving an output of 60,000 watts, and requiring 100 effective horse-power to drive. The current from these dynamos will be taken by two pairs of armoured cables to the pumps, which are placed at the bottom of the pit, and each set of pumps will be capable of delivering 200 gallons of water per minute against a head of 600ft., the pumps being driven by "Tyne" electric motors, each capable of giving 60 effective horse-power. The pumps will be of the three-throw ram type, the rams being 7½in. diameter by 12in. stroke, and the general design of the pumps will be in accordance with Messrs. Scott and Mountain's latest practice in this class of machinery, the pumps all being independent, with independent valve-boxes, thus providing against any possible breakage of either of the pumps or valve-boxes. The same firm are just completing, as mentioned in our issue of the 22nd ult., for the Shilbottle Coal Company a set of three-throw pumps capable of delivering 200 gallons of water per minute against a head of 200ft. In addition to this the firm supplied about 12 months since to the North Seaton Colliery a set of three-throw ram pumps capable of delivering 300 gallons of water per minute. These pumps have run during that period practically day and night, and have given satisfaction to the directors and officials of the Cowpen Coal Company.

Electric Lighting at Peterborough.—A special meeting of the Peterborough Town Council was held on Thursday of last week to decide whether an application should be made by the Council to the Board of Trade for a provisional order to supply electricity. The Mayor (Councillor J. Clifton) presided. For the information of the Council the borough engineer, Mr. Gill, had prepared a printed report, which we published in our last issue, and in which he recommended the Council to adopt a central station at an estimated cost of £12,500. A deputation, consisting of Messrs. W. Clarabut, G. W. Holden, and Webb, waited on the Council. Mr. Clarabut handed in a petition signed by about 140 ratepayers in favour of the electric light, and asking the Council to adopt it, reminding them that there were very few towns of this size which had not electric supply stations at work. Mr. Holden said he was very proud to support the petition, which was signed by two-thirds of the principal merchants and traders in the city, who believed the electric light could be adopted with profit by the Corporation. Councillor Miller said he was given to understand many people signed the petition under the impression that the electric light was cheaper than gas. Mr. Holden said this was not so. In reply to the Mayor, the Borough Engineer said he did not think there would be any difficulty in getting people to take the number of lights that would be required to warrant the success of a central installation. Councillor Simpson asked the memorialists if they were prepared to take the electric lighting in hand in the event of the Council refusing. Mr. Clarabut said he believed a company were prepared to take the matter up in such a case. The deputation having withdrawn, the Council proceeded to discuss the matter. Councillor J. Hunting proposed that the Corporation apply for a provisional order. He said by so doing the Corporation would be only following the example of other enterprising towns. It could not be denied that electricity was the light of the future, and they, as a corporation, had no right to adopt a dog in the manger policy, and to shilly-shally with the matter. Let them say once for all "we will apply for powers to do the lighting ourselves or allow others to do it for us." Looking at in a business point of view, and as the Corporation of an enterprising town, he hoped they would give the ratepayers the same opportunity they had in smaller towns of having the electric light. Councillor Nichols seconded, remarking that he did not think it was a speculative matter, and from the petition they might fairly judge that there would be sufficient consumers to guarantee its financial success. Councillor Miller moved a direct negative, remarking that he opposed the matter on purely financial grounds. He quoted figures in support of his argument that gas was a cheaper illuminant than electricity. Mr. Miller said that if the money mentioned by the engineer was expended it would leave but a very small margin under their borrowing powers to provide for any serious contingency that might arise in respect to the water supply or other important matters. He appealed to the Council to wait until other people had tried the experiment. The Engineer defended his figures, and stated, as a contradiction to Mr. Miller, that wherever electric lighting had been undertaken by municipal authorities it had been a financial success. Alderman Redhead seconded the amendment, and after some further discussion it was rejected and the original motion carried.

Edinburgh and the Electric Light.—Under this title Mr. A. B. Brown, of the Rosebank Ironworks, Edinburgh, writes to the *Scotsman* in reference to the report prepared by Prof. Kennedy, and which is given in another column. Mr. Brown says: "It seems to me that the Gas Commission (a body elected by the ratepayers, have not given the subject of a supply of cheap gas that consideration with the Electric Light Committee (also representing the ratepayers, which it deserves. The interests of these parties are identical, representing as they do each in their own department the interests of the ratepayer, and how the Gas Commission can supply gas at cost price for street lamps and decline to give it for other public purposes as electric supply in large quantities at such a wholesale price I fail to see. It is obvious in this electric lighting scheme that every 8-c.p. lamp will displace an eight candle burner of gas, and therefore the Gas Corporation ought to seriously consider the question of reducing the price of their gas for a large account to the Electric Committee of the Town Council to the lowest possible price, seeing that there would not be anything like the expenses of either distribution with its attendant leakages, or the collection of numerous small sums which obtains with small consumers. If the Gas Commission would only see their way to this, Prof. Kennedy's scheme would be very much simplified, inasmuch as he could use gas engines—which have now been undoubtedly proved to be much more economical than the best steam engines he is in the habit of using—with gas such as is now used in Edinburgh if supplied at 2s. 6d. per 1,000ft. For instance, no boilers are required, and consequently no stokers, no coal to be delivered and ashes carted away, no chimney-stalk, and therefore no smoke nuisances. Another important advantage is (and Prof. Kennedy knows this well) that while the best triple-expansion engine works at half load, it is a most inefficient machine; while, on the contrary, gas engines of very large power can be run at quarter or half power with practically the same efficiency as at full load. This is clearly shown in the case of the Glasgow electric lighting scheme, where Prof. Kennedy puts down the triple expansion engines in multiple; and in the case of Edinburgh, with 1,500 h.p. as proposed, he would in all probability have at least 10 sets of engines. Now, assuming the fact that the gas-engine of the present day is much more economical than the best steam-engine, then the door is opened up to the installation of the electric light in Edinburgh by numerous sub-stations, which at once relieves Prof. Kennedy from his project for the south side of a high-tension alternating system with its sub-stations of transformers with necessary attendance, and it would also dispense with a large number of the copper feeders in the northern section, due to the fact that gas-engines of moderate size could be placed close to their work. The obvious advantage, if the Gas Commissioners would work in harmony with the Electric Light Committee of the Town Council, would be this—that whatever gas lights were displaced by the electric light system, they would be compensated for by the sale of their gas, and therefore the current expenses of the gasworks by any diminution of sales would not be increased, assuming that they (the Gas Commission) are not selling their gas for street lighting under cost price. It must also be remembered by the Gas Commissioners that they, in the process of manufacture, recover the residual products—viz., tar and ammonia—

which, in the working of a steam electric lighting station, would be sent up the chimney as noxious vapours and smoke. In my former letter I did not suggest the use of illuminating gas for driving gas engines, but the manufacture of 'producer' gas from coke which is in use at the Edinburgh Gasworks. This can be made at the works at a cost of less than 2d. per thousand cubic feet, but it would be necessary to lay special mains to convey such gas, which would also be largely used for various motive power purposes. As this gas has only one fourth or one fifth of the power of the illuminating gas, it has been suggested that large mains would be required for its conveyance, but that has been on the assumption that it is to be delivered at the very low pressure of illuminating gas, which, of course, is quite absurd. With gas engines which use the gas under compression this 'producer' gas could be delivered through very small pipes at, say, 20in. water pressure, at a very small expenditure of power and at high velocity by means of a fan or equivalent blowing engines. The cost of laying these pipes of small diameter would not be anything like so expensive as the long feeders of copper proposed by Prof. Kennedy. In London the city is completely traversed by a network of pipes conveying water at a pressure of 750lb. per square inch, and Glasgow is following the example for general power purposes. With reference to Prof. Kennedy's report, there can be no objection to the electrical part, excepting the alternating high tension current system, which would disappear with the use of gas. But a grave objection in the report consists in the centralisation of the whole machinery in one centre, involving the burying of thousands of pounds as copper conductors in the ground, and also his settling a price per unit in common for both shops and dwelling houses, as well as his selection as to the districts to be traversed by his electrical feeders. Finally, I strongly advise the Town Council not to be rushed into this project, and on no account to spend this £80,000 on one station; much better spend a few hundred pounds on further investigation, as in any case they cannot possibly light the city this winter, and there is plenty of time for next, particularly if they adopt gas-engines. I am prepared to support this advice, having only a few days ago seen a compound gas engine at work of 600 h.p. near Glasgow, which is designed to produce the electric light so far as Edinburgh gas is concerned at 1¼d. per unit. I have myself had a small station of 30 lights fitted in my house in Douglas crescent for five years, consisting of a gas engine, with gas at 4s. per 1,000ft., and secondary batteries, which has been run at a cost of 1¼d. per unit, and allowing for the interest and deterioration on the plant and attendance, the cost does not exceed 3d. per unit. The reason, of course, is that there are no long copper conductors, which for the most part would be half idle in a scheme where the electrical energy emanated from one centre. The proposal, therefore, to charge 6d. per unit on such a large scale is due entirely to a large amount of sunk capital buried in the streets; and it is not likely that particularly large installations, such as hotels and theatres, will avail themselves of the supply under these circumstances."

PROVISIONAL PATENTS, 1893.

SEPTEMBER 29.

23101A. '92. **Improved methods of recovering zinc from the waste products of galvanic batteries.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop road, Balham, London. (Date claimed under Patents Rule 19, December 15, 1892.)

23101B. '92. **New or improved galvanic batteries.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop road, Balham, London. (Date claimed under Patents Rule 19, December 15, 1892.)

SEPTEMBER 25.

17972. **Improvements in make and break contacts for electric bells, fire and burglar alarms and other purposes.** Arthur Mills, 62, Great Percy street, Amwell street, Clerkenwell, London.

17980. **Improved process and means used therein for the electrolytical production of gases.** Percy Beresford Wright Kershaw, 1, Queen Victoria street, London.

17981. **A magneto-electrical igniting apparatus.** Julius Drach, 28, Southampton buildings, Chancery lane, London.

17992. **An improved composition and the production therefrom of blocks, slabs, tubes, vessels or like articles, more especially intended for the production of paving blocks or slabs, or conduits for electric cables.** Carl Jost, 47, Lincoln's inn fields, London.

SEPTEMBER 26.

18019. **Improvements in electrical switches.** John Henry Tucker, 40, Charles road, Birmingham.

18058. **Improvements in microphones.** Sir Charles Stewart Forbes, Bart., 21, Finsbury pavement, London.

18064. **Improvements in electric switches.** The Edison and Swan United Electric Light Company, Limited, and Philip Henry Bell, 28, Southampton buildings, Chancery lane, London. (Complete specification.)

18066. **Improvements in and appertaining to adjustable supporters for electric lamps and other objects or articles.** William Robert Lake, 45, Southampton buildings, Chancery lane, London. Otis Converse White, *United States.) (Complete specification.)*

18069. **An improved form of electrical switch.** William Henry Sharpless, 608A, Old Ford road, London.

SEPTEMBER 27.

18115. **A new or improved electric arc lamp specially applicable for projecting purposes instead of the limelight.** Frederick John Borland, 8, Quality court, Chancery lane, London.

18117. **Improvements in brush-holders for dynamo-electric machines and electric motors.** Horace Ingram and Alfred Ingram, 40, Durham road, Seaforth, Liverpool.

18150. **A portable secondary battery lamp for use in mines and other places.** Villeroy Corney Doubleday, 77, Chancery lane, London. Max Sussmann, Germany.)

18165. **Improvements in and connected with electric switches for series circuits.** Albert Augustus Goldston, 4, South street, Finsbury, London.

18170. **Improvements in electrical contacts.** John Smith Raworth, 46, Lincoln's inn fields, London. (Complete specification.)

18173. **Improvements in apparatus for the electrolysis of chlorides and other salts.** James Hargreaves and Thomas Bird, 191, Fleet street, London.

18175. **Improvements in switchboards for telephone exchanges.** Oswald Franz and Gustav Otto, Norfolk House, Norfolk street, London. (Complete specification.)

SEPTEMBER 28.

18188. **Improvements in or relating to electric telephones.** Thomas Sloper, 14, Britton, Devizes.

SEPTEMBER 29.

18291. **Improvements in or appertaining to submarine telegraph and like cables.** Herbert Arnaud Taylor and Joseph Arthur Lovel Dearlove, 124, Chancery lane, London.

18323. **Improvements in electric batteries.** Henry Harrington Leigh, 22, Southampton buildings, Chancery lane, London. Auguste Chevallier, France.) (Complete specification.)

SEPTEMBER 30.

18346. **Improvements in electric switches.** Edwin William Percy Cummins, Cobden buildings, Corporation street, Birmingham.

18375. **Improvements in or relating to the arrangement of electrical circuits and switches.** Joseph Arthur Montealegre, 19, Southampton buildings, Chancery lane, London.

SPECIFICATIONS PUBLISHED.

1892.

14124. **Electromotors.** Hurd.
14239. **Electricity motors.** Hookham.
16300. **Electrolysis of fused electrolytes.** Frei.
16335B. **Magneto-electric generators.** Harrison.
16335C. **Electric bells.** Harrison.
17091. **Insulating and supporting electric wires, etc.** Crompton and Dowsing.
17099. **Carbon electrodes.** Barnett.
17877. **Dynamo-electric machines.** Andrews and Preece.

NOTES.

St. Pancras.—Complaints are made of defective arc lighting of Camden-road, N.W.

Christiania.—The work of constructing an electric tramway is being carried on speedily.

School of Shorthand.—The Metropolitan School of Shorthand is now lighted by electricity.

Derby.—As described in another column, the central station was started on Tuesday evening.

Goole.—It is suggested that it would be wise policy for the Local Board to formally adopt the Electric Lighting Act.

Personal.—On Tuesday Lord Kelvin was present at a sitting of the French Academy of Sciences, when he read a paper.

Junior Engineering Society.—The annual general meeting took place last Friday at the Westminster Palace Hotel.

Newport Tramways.—The Corporation have decided to extend the tramways to the eastern district of the borough.

Madras.—The engineer of the Madras Railway is preparing plans and estimates for lighting Arkonam Station by electricity.

Bradford.—A paper on central-station systems of lighting is to be read before the Bradford Scientific Association.

Erratum.—In the review given in our last issue of "The Dynamo," read $\frac{1}{\mu}$ instead of μ.

Long-Distance Telephony.—A metallic circuit telephone system is about to be set in operation between Berlin and Cologne, a distance of 392 miles.

Insulation Resistance.—Dr. Hein, of Hanover, has devised a method of testing the insulation resistance of non-conductors surrounding electric light conductors in ordinary installations.

San Francisco.—Two months after the closing of the Chicago Exhibition, which event will take place at the end of this month, another exhibition will be held at San Francisco, in California.

Blackpool.—The municipal electricity works will be inaugurated to-morrow by Lord Kelvin, in the presence of the mayor, the chairman of the Electric Lighting Committee, and a number of invited guests.

Bolton.—Alderman Dobson, when the question of the tramways was considered last week, mentioned that the trolley system which he had seen in America was "most dangerous." Evidently Mr. Dobson has been very much misinformed on the matter.

The Transcontinental Telegraph.—The contractors for the Salisbury-Tete section of the transcontinental telegraph have left Fort Salisbury, and the material for the construction of the telegraph is now being conveyed to that place by the Beira Railway.

Engineers and Shipbuilders.—A conversazione of the North-East Coast Institution of Engineers and Shipbuilders will be held on Tuesday, the 24th inst., in the Westgate-road Assembly Rooms, Newcastle-upon-Tyne, to open the tenth session of the institution.

The County Council.—The Highways Committee have been instructed to consider how far the proposed agreement about to be made between the National Telephone Corporation and the postal authorities would affect the Council's position in regard to the telephone service in London.

Standard Sizes of Screws.—The Union of German Electrical Engineers have appointed a committee to report on the introduction of a standard size for contacts and screws used in appliances accessory to electric lighting, as, for instance, switches, safety fuses, and large instruments dealing with up to 1,000 amperes.

The Metric System.—As an indication of the growing favour of the metric weights and measures in the United States, it is interesting to note that at a meeting of the Board of Managers of Engineering Societies recently held in Chicago, it was resolved that illustrations to be drawn to scale should bear the metric scales.

Frankfort Exhibition.—Two years have elapsed since the holding of the International Electrical Exhibition in Frankfort, and although various tests were made of boilers, engines, and dynamos, the official statement of results has not yet been published. This delay is now to form the basis of an action by one of the exhibitors.

Electric Heating of Metals.—In previous issues reference has been made to the Lagrange and Hoho system of heating metals sufficiently to allow of their being welded. This method was described recently by Mr. Ross at a meeting of the Union of German Electrical Engineers, and was also demonstrated at the Hagen accumulator works.

Locomotion in London.—The Public Health and Housing Committee of the London County Council are to be requested to provide the best means of acquiring information on the question of locomotion in London, including railways, tramways, omnibuses, and steamboats. It is possible that prizes will be offered for essays on the subject.

Iron and Steel Tubes.—We have received a copy of a new and revised edition of the catalogue issued by Mr. John Spencer, manufacturer of iron and steel tubes, of the Globe Tube Works, Wednesbury. The firm make all kinds of iron and steel tubes and fittings, including wire and cable tubes for electrical purposes, telegraph poles, bases, etc.

The Halle Tramway.—The Halle Tramway Company propose to acquire for £40,000 the electric tramway worked in this town by the General Electricity Company of Berlin. The transfer would comprise the rolling-stock and the generating plant, the lines and the depôt belonging to the town. It is intended to substitute electric traction for the system now used on the other tramways in Halle.

Shiplighting.—Opportunity is being taken in Chatham Dockyard to improve the electric lighting arrangements of of whole of the first-class armoured battleships fitting and preparing for sea. The electric lighting of the ships is being taken in hand by private electrical engineering firms, the battleship "Howe" being already completed. New electric lighting apparatus will also be fitted to the battleships "Monarch" and "Agincourt."

Hard Fibre.—We have received samples of hard fibre from the Delaware Hard Fibre Company, of Wilmington, Del., U.S.A., whose European agent is Mr. J. Burns, of 15, Long-lane, London, E.C. This fibre is made in sheets, tubing, rods, washers, bushings, and special shapes. The makers state that this fibre is specially adapted for insulating purposes, for thrust bearings, pump valves, rollers, etc., and that it is unaffected by oil.

Traction at Cardiff.—As mentioned in our issue of the 29th ult., the question of municipalising the tramways has been under consideration. When the subject was discussed on Monday by the County Council, Alderman Carey pointed out the possibility of electricity being used as the motive power in connection with the tramcars. It was

ultimately resolved to appoint a committee to report on the subject of acquiring the tramway system.

Traction at Bordeaux.—An electric tramway, just over three miles long, is being constructed at Bordeaux on the Thomson-Houston system. The line is almost level, there being practically no gradients. Six cars will at first be put into service. The generating station contains Babcock and Wilcox boilers, and two steam-engines of 150 h.p. which drive four-pole compound Thomson-Houston dynamos of 100 kilowatts, the pressure being 500 volts.

Tape Instruments.—A petition has been signed by brokers and jobbers in the Stock Exchange asking the committee to use their influence with the directors of the Exchange Telegraph Company to limit the supply of their tape machines to members of the house and to such banks, newspapers, offices, and institutions as the committee may be satisfied will not attempt to use the information supplied for the purposes of dealing. Although this movement has not arisen from disinterestedness, it is a step in the right direction, but it is doubtful whether the desired object will be attained.

Telephony at Devonport. — The Admiralty have decided to establish a telephone exchange at Devonport, which will not only include within its operations all the naval and dockyard establishments in the port, but the breakwater fort in Plymouth Sound, the "Defiance" torpedo school-ship in the St. Germans River, the "Cambridge" gunnery ship, and the "Lion" training ship for boys. The system will also include a private wire embracing the whole of Devon and Cornwall, going as far seaward as Rame Head. The work has already commenced, and when completed the exchange will be the largest and most extensive that the Government have in any port in England.

Lighting of Tramcars.—The electrical engineer to the Glasgow Corporation, Mr. W. Arnot, has been investigating the merits of various batteries for the lighting of omnibuses and tramcars. The Tramways Committee of the Corporation have been authorised to ask Mr. Arnot to submit a statement showing the price at which electric energy could be supplied to batteries for the electric lighting of the tramcars, and also the cost of laying down and superintending the dynamos and other plant required for charging the batteries from five of the car depôts now being erected by the Corporation. It is is very probable that all the tramcars in Glasgow will be lighted electrically.

Submarine Torpedo Boats.—A new type of submarine torpedo boat has been built for the United States Government. It is of the ordinary cigar-shaped type, 80ft. long and 11ft. in diameter in the centre, and constructed to descend 70ft. below the surface of the water. Two quadruple-expansion engines, developing 1,000 i.h.p., will drive the vessel at 16 knots on the surface, at 15 knots when submerged with only the top of the hull or covering tower above water, and it is expected at eight knots when under water. When submerged the ordinary steam-boilers will be closed air and water tight, and the motive power provided by electric storage batteries sufficient to run the vessel for six hours under water, whilst coal will be carried for 15 hours' run on the surface.

Brake Failures.—It appears that accidents due to brake failures frequently occur on the Cincinnati electric car lines. On September 9 a car burned out its fuse wire while climbing a steep grade, and began to back down the hill. The brakes were applied, and were in good order, but the grade was so steep that the car attained high speed with the wheel sliding on the rails. The conductor and motor-man of a car which was following saw the other car coming, stopped their own car, ran ahead of it, and threw some planks across the rails, which finally brought the runaway to a standstill. Another car, on the East End electric line, in Cincinnati, broke its brake rigging on September 4, while descending a grade. It attained so high a speed that it finally left the rails on a straight track, struck a car on a switch track a glancing blow, and after running some distance over the granite pavement brought up against the kerb.

A Great Lighting Scheme.—A Greek engineer is said to have just elaborated a great project of lighting by means of the electric light the whole of Constantinople, all the Bosphorus, from Cavak as far as the historical village of San Stefano, upon the Sea of Marmora, by means of three very powerful generators to be erected upon the three points of the Bosphorus where the current has an extraordinary force—that is to say, at Arnaout-Keui, Candilly, and at Serai Bournou, at the entry of the coast port of the Sea of Marmora. The project has appeared to be so practical and realisable that a company of capitalists has been formed, the necessary funds subscribed, and a demand for a concession has been addressed to the Turkish Government. The latter, on the other hand, has taken the project into serious consideration, and, without losing time, has nominated a commission *ad hoc* to examine the details and draw up an official detailed report.

Cheap Current.—Writing on central stations in the columns of an evening paper, "M. B. C." says: "At present the demand is low, and the hours during which electric light is used are short, because present charges are so high that consumers must needs be economical. But when more people want electric light, and use it for longer hours, it will pay supply companies to establish lower rates just the same as it paid the Post Office to institute a penny post. In fact, to such an extent is this law of increased demand cheapening supply true in electrical affairs, that if there were sufficient demand to warrant a supply station running its machinery at full load 24 hours every day, electricity could be on sale at a farthing per unit instead of 7d.—a price for illumination comparing with gas at 2d. per 1,000ft." We do not know who "M. B. C." is, but he makes a very rash and questionable statement that electrical energy could be sold at a farthing per unit with a full load throughout the 24 hours.

Train-Lighting.—It is stated that the second week in November will witness the introduction of automatic electric reading lamps in some of the trains on the District Railway, and to which reference was made in a previous issue. Although this is not altogether a novelty, it will be the first permanent installation of the kind, and 2,500 lamps will be fixed in the carriages during November by the Railway Automatic Electric Light Syndicate, the previous experiments having given satisfaction. The lamp is an ingenious contrivance by means of which passengers can obtain half an hour's light for a penny. The coin, on being dropped into the machine, winds a small clock which switches on the current, and a light is produced. One battery in each carriage supplies the four lamps in each compartment. The lens attached to the lamp is sufficiently convex to concentrate the rays of light upon the paper or book of the passenger immediately beneath it. If the door of the lamp is tampered with the offender is detected, for directly it is opened a bell is rung in the guard's van.

The City Telephone Tubes.—A somewhat animated discussion took place on Tuesday at a meeting of the City Commissioners of Sewers, on the subject of the telephone tubes of the City of London Electric Lighting Company. Mr. J. Harris said it was rumoured that the company were

using the telephone tubes without the consent of the Commission, and he moved that the matter should be referred to the Streets Committee to enquire and report. Mr. Morton, M.P., urged that a strict and full enquiry should be made as to how the tubes were allowed to be put down at the same time as the electric light conduits without the knowledge and approval of the Court. Mr. Ross, the acting engineer, said that all the tubes were on the plans deposited with the Commission, but there was no indication that they were to be used for telephonic purposes. Mr. Deputy Scott, who was chairman of the Commission at the time, said he was fully aware that the telephone tubes were to be inserted simultaneously with the electric light tubes, and he considered the operation was of distinct public advantage. Mr. Berridge said the telephone tubes had been laid surreptitiously, and the Court had been hoodwinked in the matter. Mr. Morton submitted that now the electric lighting company were attempting to sell the telephonic tubes to another company. It was only when the company found that the tubes could not be used without the consent of the Commission that what had been done leaked out. It was ultimately decided to refer the matter to the Streets Committee to enquire and report upon.

Electric Light and Power at Railway Stations. The contract for an important installation of electrical plant for lighting and power purposes has just been obtained by Messrs. Westinghouse, Church, Kerr, and Co., the well-known American engineering firm. The plant represents an aggregate capacity of 1,100 h.p. in the engine-room, with corresponding equipment throughout, and is to be employed for the electric lights and motors at the new railway station now being built in Boston, U.S.A., for the Boston and Maine Railroad. Four Westinghouse dynamo generators are to be installed, coupled direct to Westinghouse vertical compound condensing steam-engines of 200 h.p. each. Two of these generators will supply current for 4,000 incandescent lights for the interior of the station, platforms, offices, etc.; the other two furnish power to a number of motors operating drawbridges, turntables, elevators, coal hoists, etc. Besides these there are two other compound engines respectively of 200 h.p. and 100 h.p. each, driving alternate-current machines for lighting purposes at stations outside the terminal depôt, and situated respectively one and two miles out. They also serve to supply current for lamps along the line, used for signalling, etc., and in the signal cabins too. Each of these engines exhausts into an independent surface condenser using salt water—the station being close alongside a sea-wharf. The boilers are of the horizontal return-tube type, 12 in number, the steam pressure being 125lb. A novel feature in the station design—so far at least as English engineering practice is concerned—is the employment of forced draught for the boilers. The chimney stack is made of steel plates riveted together, and rising only to a height of 55ft. above the ground level. Two large fans, each driven by a small independent engine, supply the draught, and either set is capable of the full service. The subsoil in this locality being extremely soft—almost mud, in fact—the advantage of doing away with a tall brick or masonry chimney stack based upon an expensive pile foundation, is too obvious to need emphasising.

Tramway Provisional Orders.—Whilst not being purely electrical, it may be interesting to refer to the proceedings of the Board of Trade under the Tramways Act, 1870, during the 1893 session. The number of applications to that Department for provisional orders under the Act, made in December, 1892, was seven—viz., Birmingham Central (cable), Blackpool Corporation, Great Yarmouth, Hull, Manchester Corporation, Plymouth Corporation, and South Staffordshire. All these applications proposed the construction of new tramways, being in every case, except Great Yarmouth, in extension of, or in substitution for, lines already in use. The aggregate length of new tramway was 14 miles 9 chains of double line, and 8 miles 69 chains of single line, the total estimated cost of construction being £173,121. The Birmingham Central, Hull, and South Staffordshire applications were ultimately dropped by the promoters. Four provisional orders were granted by the Board of Trade—viz., Blackpool Corporation, Great Yarmouth, Manchester Corporation, and Plymouth Corporation. The Blackpool and Plymouth orders empowered the Board of Trade to grant a license enabling the local authorities to work the tramways on being satisfied that the lines could not be leased at an adequate rent. In the case of the Great Yarmouth order, the deposit money not having been paid into court, the Board of Trade were unable to submit the order to Parliament for confirmation. A Bill to confirm the other three provisional orders was introduced in the House of Commons on May 5th. Petitions were presented against the Blackpool and Plymouth orders, but were subsequently withdrawn, and the Bill passed through the first House unopposed. In the House of Lords petitions were again presented against the Blackpool order by the promoters of the Blackpool, St. Annes, and Lytham Tramways Bill, and against the Plymouth order by the National Telephone Company, Limited. New clauses and other amendments were agreed upon between the parties, and the Bill received the Royal assent on August 24th. The form of protective clause recommended by the Joint Committee on Electric Powers was, with slight modifications, incorporated in the Blackpool and Plymouth orders in lieu of clauses previously inserted.

Electric Light versus Gas.—Comparisons of these illuminants are becoming somewhat wearisome. Mr. D. Terrace, the engineer and manager of the Middlesbrough Gasworks, dealt with the subject in his presidential address delivered last Saturday before a meeting of the North of England Association of Gas Managers. He said: "I should like to reiterate, however, in as clear a manner as possible, the relationship in the cost of the rival lights to the consumer—*i.e.*, light for light. This has hitherto been stated more or less clearly, and sometimes with a certain vagueness on account of the technicality of the subject." The president then gives a comparative table, and says: "It is thus that electricians compute (the 3s. 10d. against the 3s.) the cost of their light being 'cheaper than gas.' Their assumption of six units instead of 10 units, allowed by the Board of Trade as being equal to 1,000 cubic feet of gas, is a wilful playing with 'standards of light.' It is, however, done with the greatest *sang froid*. Were the gas industry to be as guilty of misrepresentation, it could with all reason adduce the latest development in economical lighting by gas—viz., the incandescent light, which reduces the cost to one-sixth of our standard, or one-fifteenth of the cost of electric light. The fair way to put it, however, is: gas standard, 2s.; electric light standard, 5s.—*i.e.*, electric light two and a half times the cost of gas, light for light." The latter seems to be a very fair statement, but we are surprised that Mr. Terrace lays stress upon or even takes any serious notice of what he terms the assertions of "one-sided advocates." The president states further that "there are about 600 towns which may be expected to use the electric light, if it were a success commercially; but only 5 per cent. of these as yet have each a comparatively small installation." Surely Mr. Terrace betrays gross ignorance on this point. Has he never

heard of dividends being paid out of net receipts by different electric light companies? He is also evidently unacquainted with the present position of electric lighting, otherwise he would not say that "as the number of towns experimenting with the new light is in a decreasing ratio, this shows that it has reached its level, and that it now appears in its proper guise in the estimation of those who may adopt it, if not in that of the electrician and capitalist." It is a pity that a gas advocate should distort facts in this manner. Mr. Terrace evidently does not read the *Electrical Engineer* or any other electrical journal, or he would be aware of the fact that the number of towns experimenting with the new light is in an increasing ratio.

Traction at Glasgow.—As our readers are doubtless aware, the Glasgow tramways become the property of the Corporation in July of next year, and in view of this fact the Tramway Committee are carrying out extensive arrangements for undertaking the traffic on the 1st of that month. It is intended that the new service shall from the beginning be complete in every detail, and after careful consideration the committee decided to erect no less than nine extensive depôts in various districts of the city, and sites for these were secured. At each of the depôts car-sheds, stables, and loose-boxes, with shoeing forge and other necessary appurtenances, are in course of erection. In addition to the usual accommodation for horses and cars, workshops for car building and repairing are being erected at Coplawhill. The buildings—which are roughly estimated to cost about £100,000—will afford accommodation for about 3,000 horses and from 250 to 300 cars and other vehicles. All, or nearly all, the cars for the service are now being built according to the design of the pattern car exhibited some time ago and approved of by the Town Council. While all that is being done points to horse traction to begin with, the buildings are so arranged as to admit of adaptation for other motors at the least possible expense, and the committee are carefully studying every system of mechanical haulage which is available, or likely to be available, for street tramway purposes, and they hope that before long, if not at the beginning of the Corporation service, mechanical traction will to some extent supersede horses on the Glasgow tramways. Extensions of the tramway system have been decided upon to improve the service, and there is every indication that the municipal tramways will be inaugurated with success. In connection with this important part of Corporation work an interesting ceremony took place the other day, when the memorial stone of the Coplawhill depôt, which is the most extensive of the stations, was laid by Lord Provost Bell. The Lord Provost said that the cars (as mentioned in another column) would be lighted with electric lamps, so that a person might read his paper on his way home. Altogether he thought they could promise that the service would be superior to the car service of any other city in the world. Bailie Paton mentioned that the Tramway Committee had had a very large amount of work to do. The buildings had been constructed so that should horse haulage be superseded they could, without difficulty, be adapted for the accommodation of mechanical motors. With regard to the question of motors, he stated that the tramway department was extremely anxious, even at the beginning of the work, that they should be able to open some routes with other motors than that of horse haulage. Whether they might succeed in that or not he could not exactly say at present, but he could give the assurance that they were not without hope that on some of the routes, at least, they might be able to accomplish that purpose. He said that great credit was due to Mr. John Young, the general manager, and his able assistant, Mr. Clark, for the manner in which they had carried out the design of the various buildings, and he believed that by the time the whole work was accomplished they would find that their capital account, upon the whole, would compare extremely favourably with that of the Glasgow Tramway Company, and would be a great deal less than that of other tramway companies throughout the country.

A New Storage Battery.—A new type of storage battery has been designed by Mr. N. Wladimiroff, an ex-lieutenant of the Russian Imperial Guard. Its construction involves several points of interest. The battery being intended specially for portable work—such as boats, train and carriage lighting, etc.—lightness was a first consideration, but at the same time attention has also been given to the other details, such as freedom from spilling of acid, indestructibility of the containing-vessel, etc. We may premise, says the New York *Electrical Engineer*, in describing this battery, that the battery is of the series type, in which one side of each plate constitutes a positive and the other a negative element, the plate itself acting as the necessary partition. A series of the plates is ranged side by side to form the cell. The lead plates, whose diameter varies, of course, with the capacity of the cells, consists of a central sheet, cast with a thin spiral web on each side. The trough or groove between the spiral webbing is filled with the active material. After the plates have been thus filled, they are assembled by clamping them between a series of hard rubber rings, which bear against the outer circumference of the plates. These rings have a thin rib running for a short distance along their lower end to catch any active material that may drop from the cells and prevent it from short-circuting the plates; rubber washers between the rings also aid to keep the cells acid-tight, the rings being grooved for that purpose. The insulating rings and the plates alternate and the space between them is filled with acid, which is poured in through a small opening at the top of each ring. In the battery exhibited at the Chicago Exhibition, 14 plates are so mounted to form one battery, and the whole is held together by iron bolts. Since each plate is positive on one side and negative on the other, it follows that the E.M.F. of each cell is added to that of the others, so that in this case each battery has an E.M.F. of over 28 volts. Each of these batteries weighs about 180lb. It may be interesting to cite the results obtained by the officers of the Russian Torpedo School last February, and submitted by them to the Chief Torpedo Inspector of the Russian Navy, as follows:

Maximum charging current	10 amperes.
Normal charging current	3 amperes.
Capacity at above current	30 to 33 ampere-hours.
Weight per watt	0·3lb.
Cost per watt	(12 copeks) 3d.
Efficiency	75 to 80 per cent.
International resistance, 14 elements in series......................	0·136 to 0·19 ohm.
Acid per element.....................	750 to 850 cub. cms.

The report also states that the handling of the Wladimiroff batteries is far easier than that of the type heretofore in use at the torpedo school. The mounting and taking apart of the cells can be readily accomplished, and no leakage takes place. As to the hardiness of the plates, a test was made, first with a current of 80 amperes for 10 minutes, and then with 176 amperes for four minutes. After the discharge had been stopped, the battery quickly reached its previous E.M.F. and capacity. On both these occasions the battery was taken apart and examined, but showed no ill-effects. Similar exacting tests were made by the Testing Committee of the recent Moscow Electrical Exhibition, as a result of which a gold medal was awarded to the inventor.

ELECTRIC SUPPLY COMPANIES.—I.

(Continued from page 271.)

WESTMINSTER ELECTRIC SUPPLY—MILLBANK STREET STATION.

We propose in these descriptions of London central stations to give the details in a form to be easy for reference or comparison. We shall briefly describe the system, give particulars of the station arrangement, generating plant, dynamos, and subsidiary apparatus, dealing in detail with any special peculiarities of plant or station, and more particularly with any recent alterations or extensions.

The Millbank station of the Westminster Electric Light Corporation is situated on the banks of the Thames, somewhat south of the gardens of the Houses of Parliament. It is a very pleasant station to visit, everything is in the strictest working order, quiet, clean, and almost noiseless.

The engineers in charge are: resident engineer, Frank Newington; second, W. Robinson; third, G. Clarke. The working staff consists of 18 men.

SYSTEM.—The distribution is on the continuous-current three-wire system, with a constant pressure of 100 volts at the houses. The supply is continuous, accumulators providing the current required during the early hours of the morning and for the light day load.

The area of supply comprises the Houses of Parliament, which have separate engines, mains, and switchboard; and the surrounding important districts of Westminster, Whitehall, Victoria-street, Great George-street, etc. This area is connected by the network of mains with the company's other central stations at Eccleston-place, Belgravia, and Davies-street, Mayfair.

STATION.—The size of the station is 200ft. by 50ft. It comprises engine-room 57ft. by 35ft., with boiler room behind, abutting on the River Thames, 80ft. by 40ft., accumulator-room above the engine-room, and the same size as this latter, with house, offices, and yard in Millbank-street.

The station is built of brick, the engine-room being lined with white glazed bricks and having a concrete ceiling carried on girders, forming the floor of the accumulator-room. The engine block is of concrete, having a minimum thickness of about 8ft. 6in. A five ton travelling crane is fitted overhead, and the engine-room is ventilated by a 5ft. ventilating fan driven by electric motor. Fire-pipes are fitted in the various departments. The station is lighted by 200-c.p. incandescent lamps, with smaller incandescents at engines and switchboards. The architect of the station was Mr. C. Stanley Peach, of John-street, Adelphi, who designed the buildings to the requirements of the chief engineer, Prof. A. B. W. Kennedy, F.R.S.

BOILERS.—The economical generation of steam power being the first essential to efficient generation of current, the details of the boiler-room should naturally first be mentioned.

There are five Babcock-Wilcox water-tube boilers (nominally 200 h.p. each) each to evaporate 5,000lb. of water per hour, the firing being done by hand. The boilers are fitted with extra steam dome, and have each a grate surface of 30 square feet. The usual working pressure is 150lb. per square inch

The furnace gases pass through a Green's economiser before entering the chimney shaft and heat the feed-water. The feed-pumps and pipes are all in duplicate, and the feed-water is measured continuously through a special meter.

Condensing apparatus is installed, but is not ordinarily in use as yet.

Best Welsh smokeless coal only is used. The coal is brought by barges up the Thames alongside the station. It is lifted by a steam crane from the barges into tipping-trucks on rails. The most careful system of weighing the fuel is adopted. Every truck is weighed by an Avery weighing-machine flush on the track, before the coal is shot into the bunkers, and the coal is again weighed on a smaller weighing machine from the coal-bunkers on to the stoking-floor before being used in the boilers; and a careful record is kept by the men in charge.

There is a complete ring of steam-pipes round the engine-room, connected with duplicate steam-mains from the boilers and having valves so arranged that any engine can be supplied in either of two ways. The pipes are freely suspended from near the roof, and were fitted by Messrs. J. Penn and Sons, Limited. They are steel pipes, 8in. diameter, with copper bends.

ENGINES AND DYNAMOS.—For continuous-current stations the direct-driven high speed steam dynamo practically has ousted other forms in English station practice. In the Millbank-street station the engines are of the well-known Willans high-speed central-valve type, and both compound and triple-expansion machines are used—compound for the smaller dynamos, which supply the Houses of Parliament, and triple-expansion for the larger dynamos for the district supply.

There are four Willans G G compound engines, working up to 90 i.h.p. each, and four triple-expansion engines of the I I type, 200 i.h.p. each—speed, 300 to 350 revolutions. In every case the engine is coupled direct to the dynamo.

The dynamos are eight in number, and comprise two Edison Hopkinson machines, giving 500 amperes at 225 volts; two Goolden dynamos, of the same output; and four smaller Goolden dynamos, giving 400 amperes at 114 volts at a speed of 430 revolutions. The latter machines are used for supplying the Houses of Parliament, or as balancing machines. Copper-gauze dynamo brushes are used.

ACCUMULATORS.—The accumulators—reservoir of energy, or flywheel, so to speak, of the electrical system—form in this station an important adjunct of the generating plant, and are housed in a large and lofty room above the engine-house. They are of the Crompton-Howell type, 500 ampere-hour capacity. There are three batteries, each with a set of 56 cells. One complete set is reserved for the supply of the Houses of Parliament.

The battery-regulating switches are placed in the accumulator-room itself, and are worked from below at the main switchboard by toothed wheel and chain gearing.

SWITCHBOARDS.—There are two switchboards situated one at either end of the engine-house—the smaller for the Houses of Parliament, and the larger for the district supply. These switchboards, built by Messrs. Crompton and Co., are mounted on slate bases, and fitted with complete switching arrangements on both positive and negative mains. Each dynamo has an automatic magnetic main switch for breaking the circuit. The voltage is read continuously by Richard Frères' registering voltmeter. The station log contains complete readings of the other instruments taken every quarter of an hour.

There is an Aron meter in the circuit of each dynamo, so as to record its whole output, and the total readings of these meters are taken to give the total output of the station. Similar meters, but specially made reversible, are used to record the daily charge and discharge of the batteries.

The pilot lines from the feeding points are brought to a multipolar switch connected to a special voltmeter, on which the pressure at the feeding points can then be read off at any moment. The station is connected by telephone to the general offices and other stations of the corporation.

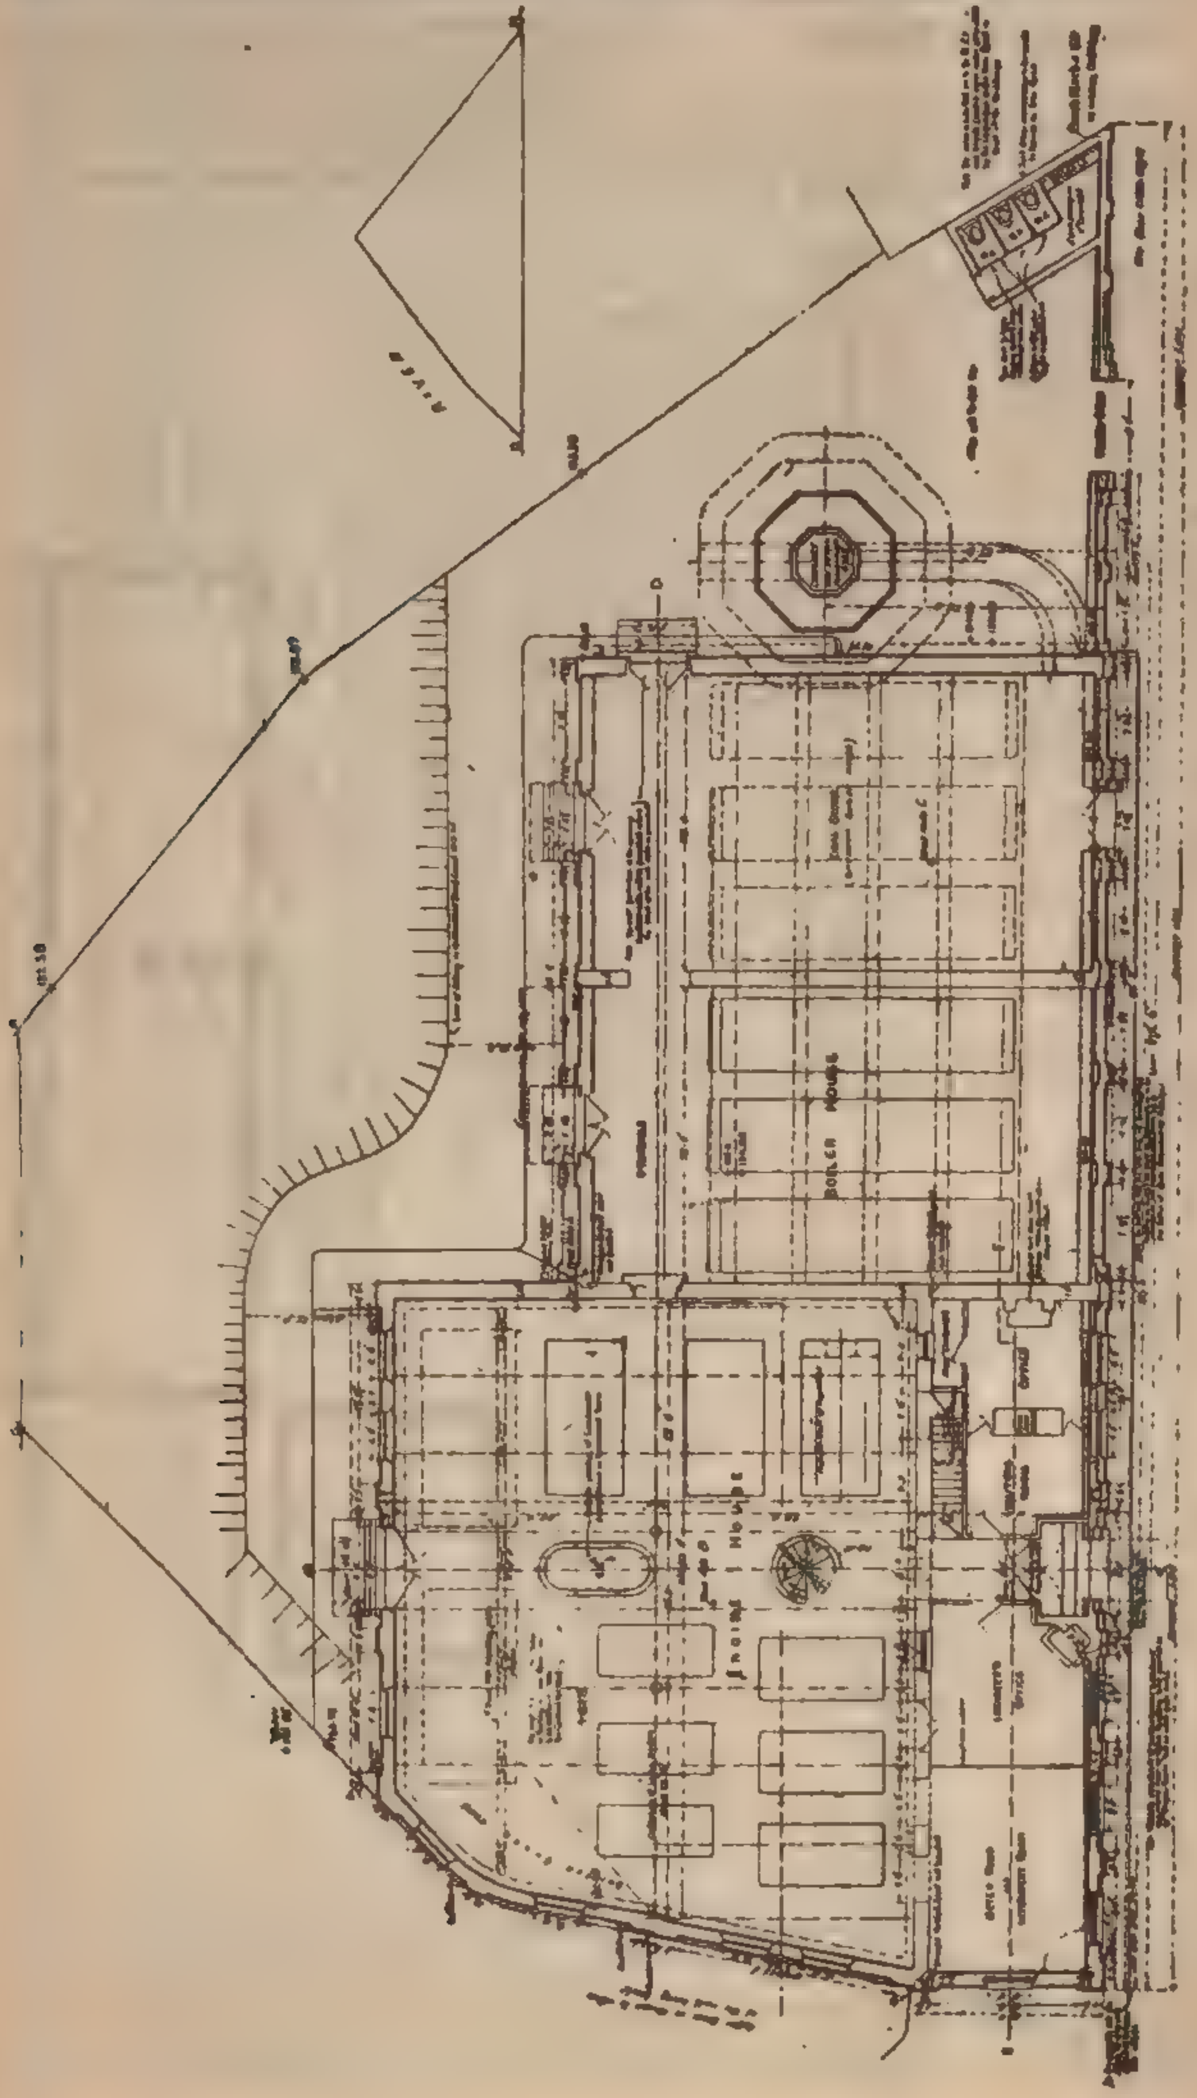
In the resident engineer's office is a complete potentiometer set—Clark cell, mirror galvanometer, potentiometer and shunt box, with secondary cells and standard resistances—used for the checking of all the switchboard instruments and of the dynamo meters.

Every item affecting the cost of generation of current is scrupulously looked after and checked under control of the chief engineer, Prof. Kennedy.

This station—quiet, orderly, with every item thoughtfully arranged—is a model instance in the centre of London; and the extreme constancy of supply forms the best test of working efficiency.

After describing the arrangements in the other two stations of the Westminster Corporation, we shall have, by the kindness of the corporation and Prof. Kennedy, some interesting details to give with reference to the cost of generation of current on the Westminster Corporation's system.

(To be continued.)



Derby Central Electric Lighting Station.—Plan of Site, showing General Arrangement of Buildings.

DERBY CENTRAL STATION.

It will not be necessary to enter into any lengthy history of the action of the Derby Corporation in determining to provide the electric light for the borough and to undertake the work themselves. An enlightened policy is sure to have its own reward, and within a few years, when the works reach their normal development and bring normal returns, it will be seen that the reward will be commensurate with the energy expended. Come we, then, to the time when the authorities had made up their minds and placed the designing of the station and distributing system in the hands of Messrs. Bramwell and Harris, consulting engineers of the greatest experience and highest repute.

The determination of the site led to some sharp criticism, but one cannot fail to assume that engineers of so great eminence are better judges of what is best than lay critics, who are too apt to consider one prominent point only. Time alone can prove the wisdom of selection. The site actually selected possesses great historic interest. The first silk mill erected in England was built here, about 1718, by Mr. John Lombe, who procured in Italy (by, it is said, bribing two workmen, who accompanied him to England) drawings and models of the silk machinery then in use in that country, for which he took out a patent. This patent covered the operations of winding, doubling, and twisting the silk so as to render it fit for weaving. The initiator of this industry, it is said, died about four years after from poison administered by an Italian female sent over for that

purpose. Be that as it may, his cousin, Sir Thomas Lombe, relinquished the patent in consideration of the sum of £14,000, whereby the manufacture was thrown open and the trade rapidly increased. It seems almost a pity that Derby was not before Bradford in their electrical enterprise. To have had the first silk mill, to have had the first lightingstation, would have been achievements worthy of history. Although Derby cannot claim to be first as regards electric lighting, it comes in at a very early point in the history of such enterprises, and this shows the determination of its authorities to be among the first to patronise any phase of civilised progress as soon as it has been shown to be progress.

THE REIGN OF KING MUNICEPS.

The day is long since gone by when one might look round and notice the first movements of the tendency — now become general — towards self-government on all points of common local interest by the centres of population and industry. We are almost tired of reiterating not only the theoretical proposition that municipalities ought to take in hand the supply of gas, water, and electric light, the disposal of refuse and sewage, the provision of more rapid suburban transit, and numberless other such public duties, but also the actual fact that one local authority after another falls in line, and as the demand arises forthwith proceeds to carry out the required public service—as a rule, with perfect success.

Within the past fortnight alone, for example, so far as concerns the supply of electricity for public and private lighting from municipal central stations, we have seen the opening of such works at Manchester, Derby, and Blackpool, with some little amount of quite excusable glorification in each case. Many have preceded these, as our list of corporation authorities will show, and still more are yet to follow their example in ever-increasing number. Everyone at all well acquainted with the conditions of development in the public supply of electricity for light and power purposes must by now be fully aware of the many utilitarian advantages which lie on the side of municipal undertakings as opposed to the interests of a private company; and the same result appears, indeed, to happen whether the article to be supplied is gas, water, or electricity.

There is no need to recapitulate the reasons for this condition of things; it has grown of increasing importance each year, and to judge from results, can as yet be in no way regretted. Municipal enterprise is admittedly well able to supply centres of population with at least some requirements of healthy and prosperous living—pure water, for instance, and a good artificial light for the hours and places wherein Nature fails us.

Not only is this a matter of general agreement in regard to the equipment and ownership of gas and water works, electric light stations, etc., but the successful daily working or commercial operation of such by municipal bodies may also be considered sufficiently proved by experience. When, however, we come to the question of improvement in suburban transit methods, the installation and equipment of new tramway lines, or the purchase of those already established, with a view to increasing the facilities of locomotion from one part of a city to another, we find a widely spread difference of opinion as to the true sphere of a local authority.

There are many whose opinions cannot be disregarded, and who claim that the system of tramway lines, existing or proposed, in any centre ought rightly to be municipal property—apart, that is, from any consideration of the Tramways Act, 1870, and the powerful position in which that enactment places the local authority in regard to compulsory acquisition of the lines after a period of only twenty-one years, as compared with forty-two years in the case of electric lighting systems. But they draw the

line at mere ownership, and will not agree that municipalities should be empowered also to operate the tramways of their respective districts.

Others, again, consider that the duties involved in the working of any transit system, though perhaps of different character, are no greater than have already been undertaken by local authorities in many places; and they consider it to be unjust that shareholders in a private company should derive substantial benefit from what is to all intents and purposes a monopoly of public transit. As for that, reply the anti-municipals, in too many cases the shareholders receive next to nothing in comparison with other investments, and if the tramways are to be carried on by the local authority in each town, there would arise a grave danger of considering the passenger or employé before the ratepayer, besides which the feeling of personal responsibility is, as a rule, more acute in a management financially interested to a large extent than with a committee whose members have only to resign on account of ill-health when trouble begins. Moreover (taking the war into their enemy's camp), they say that a tramway system supported by the rates holds a most unfair position with respect to any competitive enterprise employing private capital to operate, say, a line of omnibuses.

Both sides admit the absolute propriety of local authorities taking over or owning *ab initio* the tramway systems, but the one party maintains it to be truer policy for the operation of the lines to be undertaken by a private company—of course, under suitable conditions and restrictions, and upon a terminable lease. The other party holds, in the first place, that the progress of invention and improvement in tramway matters has shown conclusively that mechanical powers are the most suitable to employ for traction purposes even along our streets. In all probability, therefore, the conversion of existing lines now operated by horse power will be largely a question of time and money; whilst new lines and extensions in many cases will doubtless be equipped with electric or cable motors.

Since local authorities are beginning to show what they can do in the way of profitably carrying on such undertakings as electricity works for the supply of light and fixed power, they ought surely, it is claimed, to be in a position satisfactorily to operate an electric tramway, the working conditions being the same for all practical purposes.

Such, in brief, is the question which is forcing its way to an early settlement, and which will therefore come very prominently before the public during the immediate future.

The general tendency in other countries has been, of course, increasingly to employ mechanical traction upon street tramways; proofs of this are seen everywhere. We print elsewhere a paper on "Earth Returns," read before the eleventh annual meeting of the New York State Street Railway Association, whose members used at first to discuss forage and fodder; in a recent issue we gave an abstract of the favourable conclusions respecting electric traction reached by the International Tramway Congress at Budapest; the Tramway Institute of our own country makes a point of meeting wherever new electric traction developments are to be found, with a view to giving its members an object lesson in the latest progress made.

Assuming, therefore, that our tramway systems are sooner or later (let it, we hope, be "sooner") to be operated by mechanical motors, the next question to be decided (and we simply state it without attempting in this place a final conclusion thereon) is the following: "Have local authorities proved themselves to be strong enough generally to undertake the confessedly difficult and often thankless task of operating tramway and street transit systems—more particularly with mechanical motors—taking into account the excellent position already attained by them in, for instance, the matter of electric supply for lighting purposes?"

Tentatively, one would feel inclined to say, that so long as local authorities can give an efficient rapid transit service with satisfaction to the public who ride, and the employes who do the hard work, and, whilst accomplishing this, are able to show a balance, however small, on the right side of the ledger, there does not seem any reason for the existence of tramway companies to operate the lines.

Probably we have thus raised a high standard, but it is one to which King Municeps must aspire, if he wishes to extend his realm. Any additions to his rule must be self-supporting, although not necessarily productive of a big revenue.

DERBY CENTRAL STATION.

(Concluded from page 347.)

As will be seen on examination of the place of the supply area, a part of the site of the old silk mill has now erected upon it the generating station. We had an opportunity of thoroughly examining the plans and seeing the work being done at the station during the course of construction, and it was gratifying to see the great care and attention which had been and was being bestowed upon every detail.

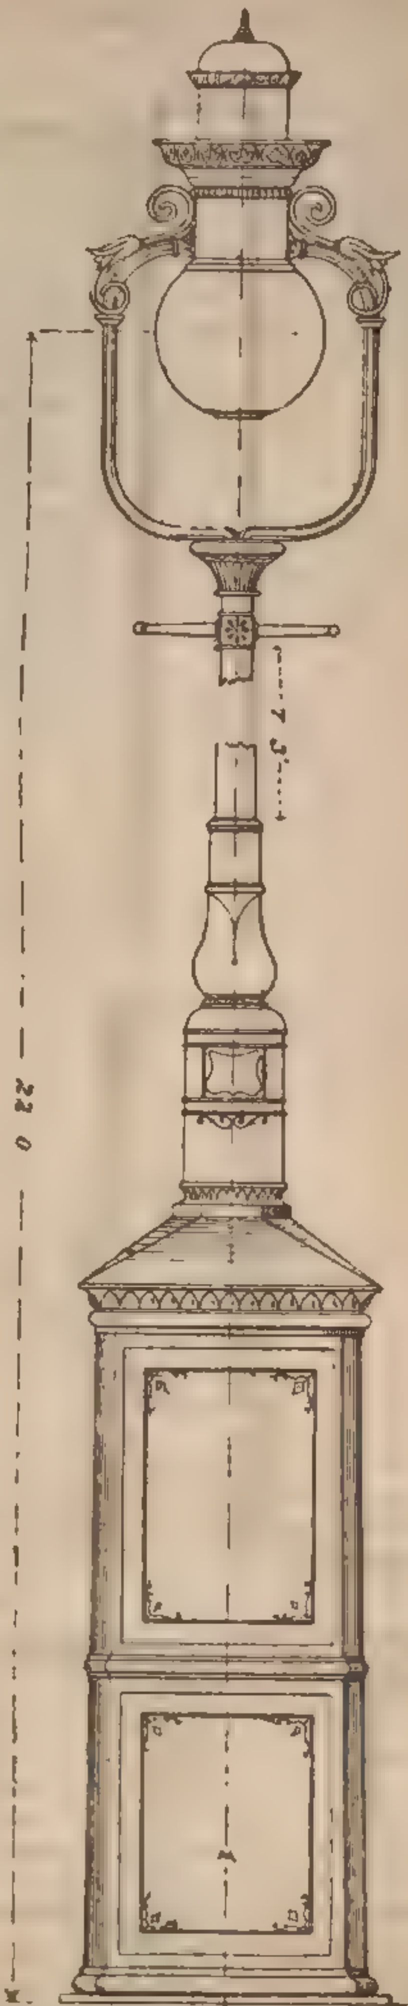
But just another word about the site. The shape is, roughly, triangular. The silk mill was built upon piles, and during the excavations for the station many of these were met with in an admirable state of preservation. The historic associations connected with the site must, however, give place to the practical, the most important of which relate to position, to suitability of foundations, and to maintenance in enabling coal to be brought to the boilers. As to position, we have said it was selected after careful examination of all the facts. Trial holes were made to ascertain its suitability for foundations, and being alongside the river, water for condensing was obtainable in quantity, and, if necessary, coal storage and water carriage was obtainable. Assuming, then, that the site was the best obtainable, the next question was the design of the buildings, and as these are fully illustrated it will be necessary to say but little about them. From first to last the engineers have had in view the saving of losses during working, and hence the minimising cost of maintenance. This in our estimation should be the aim of every designer. Initial cost is of secondary importance, cost of maintenance is of primary importance. But the electric light engineer is handicapped in other ways. He has to design for initial economy, for economy of maintenance, and at the same time allow for future and rapid extension. We must congratulate the engineers upon their careful design of this station. The plant can be duplicated with a minimum of additional expenditure.

So far as the buildings are concerned it will not be necessary to enter into lengthy description—the illustra-

tions tell more than a volume of word-painting; hence for the moment we will rest satisfied with generalities rather than with particulars. The whole of the buildings are substantially built, and special attention has been paid to the dynamo foundations, which are of concrete capped with Derbyshire sandstone. Of the electrical equipment only a part of what is even now contemplated is fixed, but the remainder is being rapidly pushed forward. There are three of Fletcher's boilers of the ordinary Lancashire type, with Galloway tubes and Vicar's automatic stoking apparatus, driven by an independent engine. Each boiler is of 200 h.p., and delivers steam at the working pressure of 120lb. These three boilers fill one bay of the boiler-shed. There is a second similar bay, and another bank of boilers can be erected as soon as required. The boilers are fitted with both injector and donkey pump. The steam-pipes are arranged so that steam can be admitted or shut off from any boiler. These pipes are carried through the boiler-room wall underneath the dynamo-room to the engines. There are two sets of exhaust-pipes—one set going to air, the other to

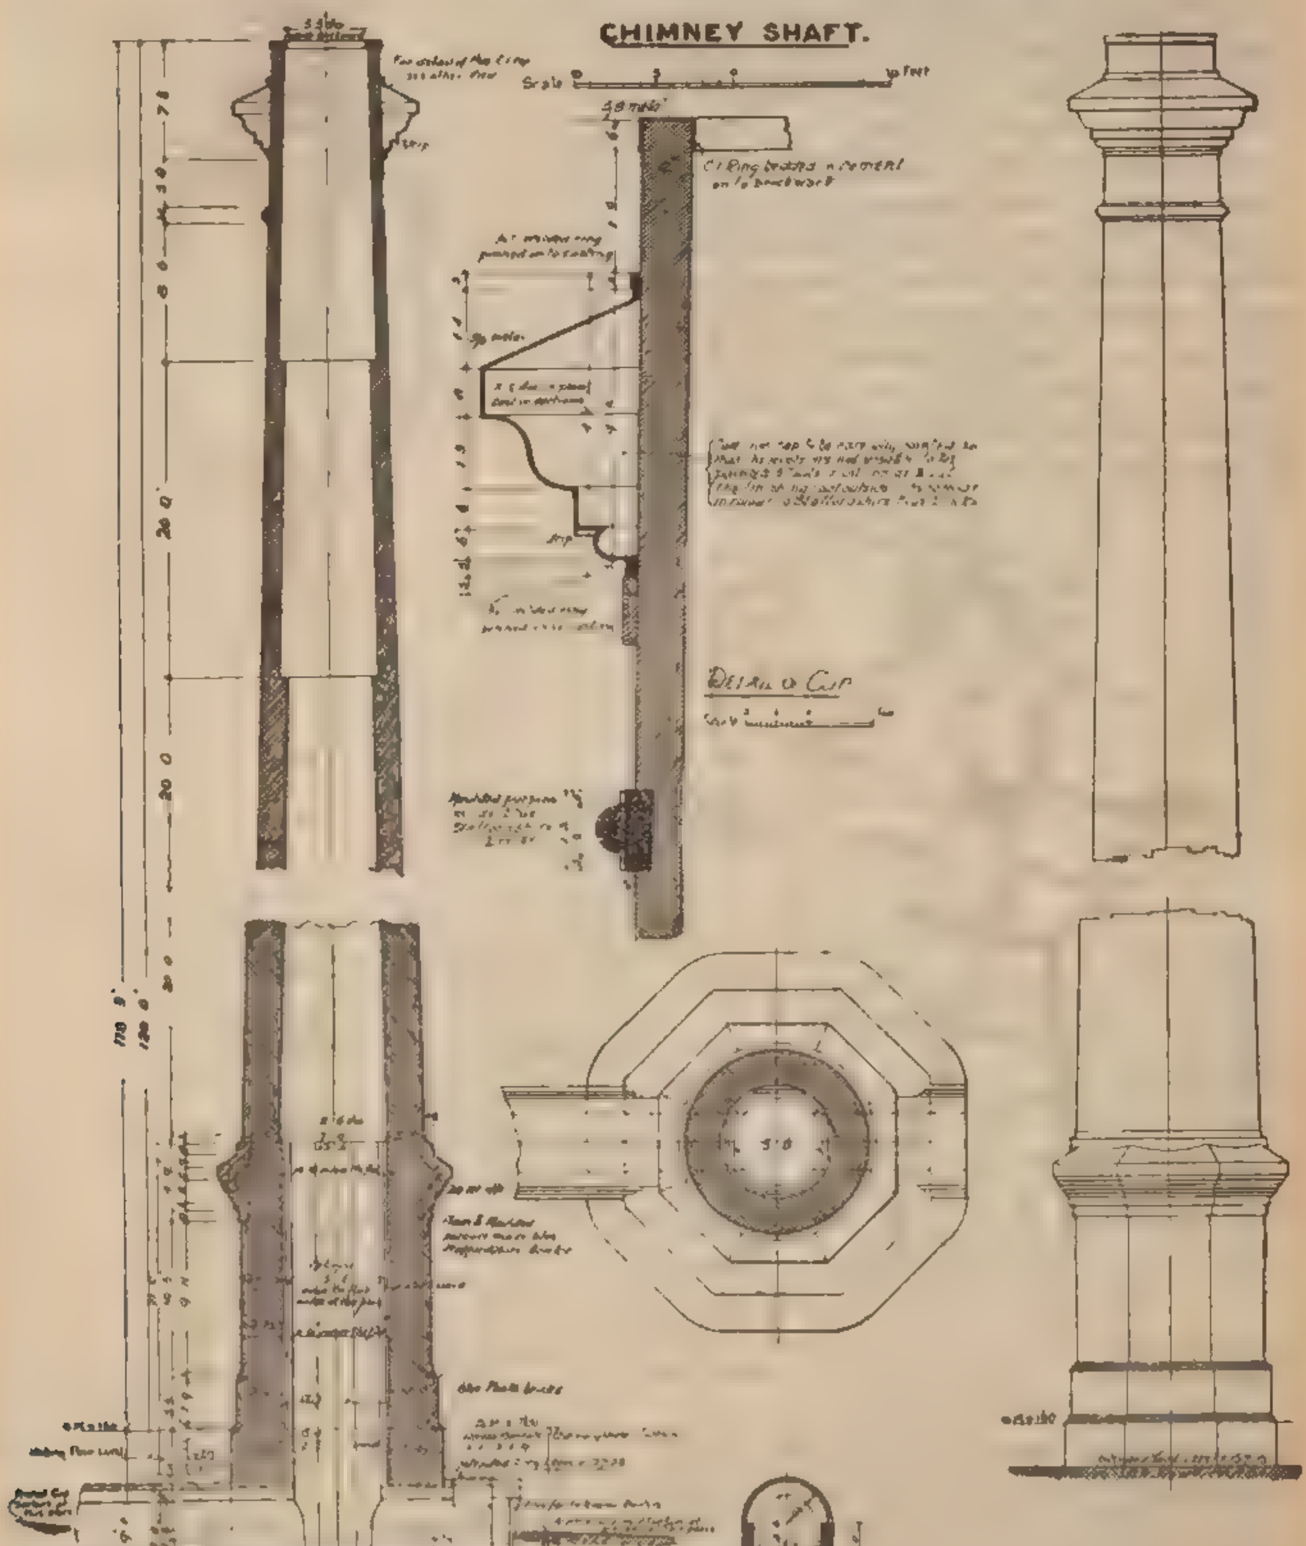
Derby Central Electric Lighting Station.—Map showing Compulsory Area of Supply.

the condenser, the circulating pump for which gets water from the adjoining river. The engines are by Messrs. Browett and Lindley, of Patricroft—vertical, compound, direct-driving, with flywheel governors. Those installed are to give 50 h.p. actual, while three others are being erected of double this power. At the present time these engines drive three alternators by Messrs. Siemens and two direct-current dynamos—the latter for the arc lighting. These alternators deliver current at 2,000 volts at 200 revolutions per minute, and have the exceedingly low periodicity of 40. The exciters are by the same makers, and run at 300 revolutions per minute. The arc lighters run at 300 revolutions, giving 10 amperes at 1,800 volts. In fact, this output is obtained at 280 revolutions. Each of the arc lighters is intended to give current to 40 lamps in series. At the present time there are two arc light circuits. The lamps are Siemens's double-carbon, to run 36 hours—that is, each pair of carbons last 18 hours; and the first pair being consumed, the second is automatically brought into circuit. The leads from the alternators are *taken to* omnibus bars, as they are intended always to run *in parallel, and from these the current* is switched to all or



Derby Central Electric Lighting Station.—Combined Lamp-post and Transformer Box.

any of the transformers on the feeder circuits. The switchboard is arranged for 12 circuits. We ought to have mentioned that the high-pressure fuses are in porcelain voltage of any feeder at the transformer can be told at any moment. The transformers themselves are housed in the columns which support the arc lamps.



Derby Central Electric Lighting Station.—Details of Chimney Shaft.

boxes, and that all the switchboard arrangements have been carefully considered, the double-pole switches being insulated with ebonite. Pilot wires are brought back to the switchboard, from which incandescent lamps are run, and by means of a switch and a Cardew voltmeter the

A few words with reference to the system of the distribution and the general features of this installation will be known. All the transformer secondaries are led to what may be termed omnibus distributing-mains, from which mains the incandescent

lamps are fed. It will be seen that when the demand is light the transformers not required to supply the demand can be switched off, and so the transformer losses at low load avoided. In fact, though there may be a little loss by this omnibus method, it will probably be far less than the loss would be by using transformers at low loads. But we hope to illustrate, and where necessary describe, the various details of the apparatus in subsequent issues.

Meanwhile, on Tuesday evening, at the invitation of the Mayor of Derby (Mr. Councillor Marsden, J.P.), a large number of the most prominent inhabitants of Derby gathered together at the central station to witness the inauguration ceremony of turning on the steam, and subsequently to dine together and felicitate each other upon the success so far achieved. The ceremony was a success, the light was a success, and the speeches were a success. The Mayor admitted that the Corporation had placed itself unreservedly in the hands of the Electric Lighting Committee, and that the committee had placed itself as unreservedly in the hands of the eminent and experienced engineers, Messrs. Bramwell and Harris. We are quite sure that this was the wisest policy to pursue, and our examination of the works when in progress and again so far completed, lead us to the conclusion that Messrs. Bramwell and Harris have designed a station worthy of the town and their own great reputation; and they have been ably seconded by the various contractors, such as Messrs. Siemens, Messrs Browett and Lindley, who have supplied the engines and dynamos and other apparatus. Nor must we forget the gentlemen who have superintended the actual work, and to whose unremitting attention the success of the work is due.

THE RETURN CIRCUIT OF ELECTRIC RAILWAYS.*

BY THOS. J. M'TIGHE.

(Concluded from page 327.)

I must not take up your time with any extensive analysis of Table III., but I cannot forbear pointing out a few striking features. Take cases Nos. 2 and 6. The former is, no doubt, used by many members of this association. No. 6 is the system track circuit of the Atlantic-avenue Railroad, in Brooklyn, N.Y. No. 2 has a total track resistance of ·0586 ohm, and costs for material about 700dol. per mile, while No. 6 has a total track resistance of but ·0130 ohm, and costs for material only 144dol. per mile. In other words, No. 6, in point of efficiency, is four and a half times a better electric circuit than No. 2, while costing just about one fifth as much

TABLE III.—Characteristics Per Mile, Double Track.

Case number.	Total R of rails.	Total R of rail bonds.	Total R of track circuit.	Fall of potential for 200 amperes	Total energy expended thus in track circuit.	Cost of such per year at 100dol. per kilowatt	Approximate cost of track circuit material
	ohm.	ohm	ohm.	volts.	watts	dol.	dol
1	·0086	·0335	·0362	7·24	1,448	144·80	700·00
2	·0086	·0671	·0586	11·72	2,344	234·40	700·00
3	·0086	·0796	·0882	17·64	3,528	352·80	90·00
4	·0086	·0398	·0484	9·68	1,936	193·60	180·00
5	·0086	·0133	·0218	4·36	872	87·20	180·00

10	·0086	·0027	·0113	2·26	452	45·20	150·00
11	·0067	·0335	·0306	6·12	1,224	122·40	1,250·00
12	·0067	·0011	·0078	1·56	312	31·20	432·00

In roads likely to have extreme heavy traffic, case No. 11 has been adopted, there being four No. 0 supplementary copper wires and the ordinary copper rail bonds or connectors, being thus merely an enlargement of No. 2, and used in connection with 90lb. rails. In case No. 12 the 90lb. rails are also used, but there are no supplementary wires, and each joint of the rails is supplied with two rail bonds of No. 0000 copper wire, each only 12in. long. Comparing results, it is evident that case No. 12 is, electrically, about four times a better circuit than No. 11, while costing only about one-third as much.

Now, let us compare case No. 12, as it stands, with case No. 11, but adding to the latter two 500,000 circular mils overhead returns connected heavily to the track circuit at frequent intervals. In case No. 11, the total track circuit resistance is ·0306 ohm; that of the two 500,000 circular mils feeders about ·0545 ohm; and the combination circuit measures about ·0196 ohm. The cost of the two feeders (insulated) per mile of double track roads would be approximately 2,800dol., to which we add the 1,250dol., cost of track circuit in case 11—making 4,050dol.

In short, though our case No. 12 gives us almost three times as efficient an electric circuit as the new case No. 11, the latter costs almost 10 times more than No. 12. And yet the West End and Brooklyn City Railroad Companies pin their faith in a circuit like case No. 11.

A glance at the sixth and seventh columns of Table III. is rather instructive. If we take a medium city system operating 20 miles of double track, the company which uses case No. 2 will pay several thousand dollars per year for the energy wasted in the return circuit, while the company using No. 6, or No. 8, or No. 10, will pay but a trifle in comparison, and save nickels by the quart. I am of the opinion that it would, to-day, well repay any company using copper supplementary wire to rebond its tracks on a basis of perennial low resistance, because on the average it would save the cost of such change in one year. And I say the same to those using iron rail bonds.

There is still another phase to this whole question of the return circuits to which I will briefly refer. I mean the electrolytic decomposition of the rails when earth is relied upon as the major part of the return circuit. That there is such decomposition must be true. The soil under our paving has for many years been plentifully soaked with ammonia from animal refuse, with ordinary salt in the winters of bygone horse-car days, and to these have been added the leakage from the underground gas-pipes. Certainly, such soil, when wet and in contact with the rails, presents all the requisite features of an active depositing bath, there being no dearth of cathodes below. Hence, so long as a considerable flow of current takes place from rails to earth, there must necessarily be a good deal of direct electrolytic decomposition of the rails. Let me take an extreme case. It would scarcely be exaggeration to assume that on Tremont-steet, Boston, or Fulton-street, Brooklyn, there is a massing of slowly-moving cars, amounting to, say, 100 for one mile of double track. Let the rails used be 70lb. girder, and for the current I should say 20 amperes per car for 15 hours per day would be a fair average; $100 \times 20 \times 15 \times 365 = 10{,}950{,}000$ ampere-hours per year. If all this went back to the generator by way of the earth, the decomposition of the rails every year would be 7,665,000 grammes, or about 17,000lb. of iron. Nearly eight tons lost from the mile of double track in one year. As the mile of 70lb. rails would only aggregate 220 tons, it would not be many years at that rate till the rails would be qualified for a pension for loss of both feet incurred in the service, and in time we might have an illustration of the proverbial "two streaks of rust and a right of way."

I have assumed an extreme case, but I have no doubt that there is a considerable amount of direct electrolysis of the rails. Nothing can be done to entirely avoid it, but it can be reduced to a minimum by overhauling the track circuit and giving it as great an electrical value as possible, and it might be retarded by dipping the rails before laying, similarly to gas and water mains. In abandoning as much as possible the rather uncertain supposed advantages of the earth return, we would to a corresponding degree rid ourselves of troubles with gas and water pipes and telephone circuits, and yet would be as safe from lightning as we are at present.

If it be admitted, then, that it is desirable to obtain from the track structure as great a conducting power as possible, the question arises, how shall it be done? This at once brings us to the subject of rail bonds, and a criticism of the various types used, with a view of arriving at the best from all points of view.

* Report read before the Street Railway Association of New York State, September 19, 1893.

There have not been many types brought out by the manufacturers. Probably the earliest was made of a piece of wire having its ends coiled around two rivets and dipped in solder. This form is still much used, but it is objectionable. By its use four contacts exist at every rail joint—*i.e.*, rail to rivet, rivet to wire, wire to rivet, and rivet to rail. To ensure its position in the rail the rivet must be upset, and this in a great number of cases either starts or completely loosens the contact between the rivet and wire. If it escapes this, the constant vibration of the rail sooner or later causes loosening of the wire on the rivet. Once looseness occurs, the bond is of little use. Again, the essential nature of such a rail bond precludes the use of any large wire in its construction. Still, many roads have used them and are still doing so. The wire generally used is No. 4 B. & S., sometimes iron and sometimes copper.

Another type which has met with much favour consists of two soft iron pins with enlarged heads, which are drilled transversely to receive the connecting wire, which is upset after passing through the heads. This form is open to the same objections as the previous one, being in three pieces, the integrity of whose contact is almost sure sooner or later to be destroyed, whether the intermediate wire is iron or copper.

Later on appeared the ingenious and, from a purely constructive aspect, very economical "channel pin." It met an enormous sale, and is to-day in extensive use. The form is familiar to you, and I need not describe it. It requires three pieces, is not capable of riveting in the rail, and its form prevents the pin and wire from completely filling the hole in the rail, and rapid corrosion of contact is inevitable. Being merely driven wedge-like into the rail hole its stay is not reliable, and by corrosion and continual vibration it becomes loose and almost valueless. There is, too, a tendency for the workman to force the wire against the sharp edge of the hole while driving the pin, thus weakening the wire very materially. It, too, like the rivet-and-wire bond, has a limitation as to the size of the connecting wire. No matter how carefully the mechanics of the job are attended to, we have a mere plug driven in a hole, and so between the rail and channel pin and the car wheels is a very good illustration of a cask, a bung, and a bung starter, with the odds against the bung.

Another type of rail bond is that composed of a piece of copper wire, with cast copper rivets electrically welded thereto on projecting stems the size of the wire. This is an attempt in the right direction, but does not work out in practice. The electric weld is apparently uncertain, the union in many cases under my inspection being so imperfect that it could be broken by hand. The small copper castings exhibit radial crystallisation, making welding difficult. Many also break in applying to the rails, and such happenings destroy confidence.

I now come to what is known as the "solid one-piece bond," which has sprung into great favour. It would be disingenuous were I not to announce right here that this rail bond is a patented invention of my own, but I hope that you will admit that I am trying to view this question from a broad and disinterested standpoint.

This solid one-piece rail bond is simplicity itself. It is merely a wire with expansion curves at its ends, on each of which a heavy shoulder is swaged from the wire itself, so that both the rivet ends thus formed and the intermediate wire are all one solid integral piece. From rivet to rivet there can be no failure of contact, except by forcible rupture or total corrosion, and there can be no failure of contact between bond and rail, because when the rivet end is properly headed up, the connection made is perfectly watertight and airtight, and it is proof against pounding and vibration. There is no solder required, no parts to shake loose, and there is no restriction in size of wire, as the bond can be made of No. 4 wire, and it can be made of No. 0000, and larger if desired.

I suppose the great majority of rail bonds used span around the fishplates, which nowadays are quite long. My belief is this is a mistake. Table III. will show what a difference there is in resistance in the track circuit as between 36in. and 12in. bonds. The 12in. bond has the advantage in the total track resistance of from 40 per cent. to 50 per cent. A 12in. solid bond, with its expansion curves, makes a distance between rivet centres of about 8in. Electrically considered, it does not matter what part of the rail end is used for bonding. The holes can be drilled through the flat "tram," or through the floor of the rail, 4in. from the end, just as readily as through the web or stem. There is no difficulty whatever, and I can imagine no type of track construction forbidding the use of short bonds. I have bonded many miles of track in this manner, and used the 12in. bonds and had no trouble. In girder rail I prefer to drill the holes through the flat tram, taper ream the holes from above, and deeply countersink; then pass the rail bond up from beneath, and head up the ends till the taper and countersink are completely filled. This method has one great advantage, in allowing every rail bond to be inspected at any time without disturbing the paving. The tracks of the Atlantic-avenue Railroad, in Brooklyn, were bonded in this way with No. 000 copper bonds, 8in. long between rivet centres, and they have given entire satisfaction.

Rail bonds should, after being applied, be either heavily coated with shellac and asphaltum, as practised by Mr. Wason in Cleveland, or have a grooved strip of wood filled with asphaltum slipped around while the compound is soft. This will prevent corrosion.

Another important element of the return circuit, in such roads as do not pass the power-house, is the main return. Whether earth circuit is used or not, there should be a heavy connection from the generator or switchboard by the shortest route to the rails. Such a course is generally adopted, but the size of the conductor is apt to be too small. I have seen several cases of serious inadequacy in this direction, so much, indeed, as to heat the main return. I had occasion once to discuss the question with a gentleman who called himself an electrical engineer, and who had engineered several railways of considerable size. The problem was to return a possible maximum of 5,000 amperes about half a mile from tracks to generator. I gave my views, which embodied rather heavy work, and also my calculations for loss of energy, etc. "Nonsense," said he, "four No. 0000 wires would be abundance, because you can lay them in the ground, and the heat will be carried off before harm can be done." It was no use arguing against that, and I utterly failed to persuade him that his four wires would required 320 volts to drive the 5,000 amperes through them—*i.e.*, a loss of over 2,100 e.h.p. Fortunately that engineer has generally had some check on him, and thus the construction of several monstrosities has been avoided.

The old rails can be advantageously used for the main return in many cases. When it comes to using a large number of heavy copper wires overhead or underground on the one hand, and on the other hand an equivalent capacity of old rails laid underground, the latter is much cheaper, and can be made entirely durable. The rails can be connected by heavy copper plates by riveting, the number of rivets being equal in carrying capacity to that of the rail and plate. The whole structure can be laid in a wooden trough filled with pitch, and will remain intact for an indefinite period. A one-rail line of this kind, composed of old 60lb. flat or centre bearing rail, is as good as a copper bar 1in. square, or six No. 0000 copper wires.

I am, therefore, led to the conclusion that the best return circuit is that which complies with the following requirement: (1) Intrinsic resistance low enough to need no help from earth; (2) utilisation to the utmost practical extent of the rails as the return conductors; (3) rail bonds of the heaviest practicable size; (4) rail bonds of the shortest possible length, consistent with due allowance for expansion and vibration; (5) rail bonds made of a single piece of wire with integral rivets; (6) rail bonds tightly riveted to the rails through holes freshly reamed immediately before bonding; (7) rail bonds so placed as to permit convenient inspection; (8) rail bonds protected against corrosion; (9) a very liberal use of heavy cross bonds from rail to rail direct, and, in double track, extra heavy cross bonds connecting the two inside rails; (10) an underground main or trunk return from the power-house to track, and there connected to each line of rails, and low enough in resistance to carry the maximum current with but a nominal drop in potential.

Not one of these requirements is an extravagance, but, on the contrary, their proper application to almost any electric railway in the country would be of immediate and lasting benefit. In new constructions they would be a positive economy in first cost. There is not one of them which cannot be adopted in practice, and it seems obvious that their complete embodiment in any existing road would be immediately noticeable in the power-house, and eventually in the dividend.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE II.

THE STORAGE OF ENERGY AND THE DEVELOPMENT OF ENERGY BY WATER POWER.

In most applications of the energy derived from fuel the fluctuation in the demand for power involves waste. But it is in steam central stations which have to work during 24 hours, during which the demand for power varies very irregularly, that the waste due to irregular working has been most serious. Of all central stations, electrical central stations are those which have to meet the greatest fluctuation of demand for energy, and the waste so occasioned has compelled electrical engineers, more than any others, to seek for means of storing energy.

To completely meet a fluctuating demand by generators of energy worked at a uniform rate, there must be storage of energy satisfying two conditions. Twenty four hours may be taken as the natural period of the fluctuation of demand for energy. In each 24 hours there will be two periods—one in which the demand falls below the average demand, and one in which the demand exceeds the average demand. The excess of energy supplied during one period will on the average be equal to the deficiency in the other period. If the generators are worked at a uniform rate, then all the energy supplied in excess of the mean demand in one period must be taken from storage, and must have been put into store during the period in which the demand fell below the mean demand. But this is not the only condition to be satisfied. With some kinds of storage, the rate at which energy can be taken out of store is unlimited. In other cases it is limited, and then the storage must be so arranged that the rate at which energy can be taken out of store is equal to the difference between the maximum rate at which energy is required and the mean rate.

Gasholder Storage.—The distribution of gas is not strictly a distribution of energy, but only of the means of conveniently obtaining it. But a gas lighting distribution is analogous to a distribution of energy, and the demand varies nearly as much as in an electrical distribution. The gas engineer is happy in having a convenient and cheap means of storage. Usually about 24 hours' supply of gas is stored in the gasholders at a gas generating station. Hence the gasmaking plant can be worked at an almost uniform rate day and night. Taking 25 cubic feet of gas as capable of yielding one effective horse power hour of energy, it appears that gasholders cost about 5s. 6d per effective horse power stored. Mr. Trewby puts the cost of gasholders at a London station at £10,000 per million cubic feet of gas supplied per day. In that case such a station works virtually at 1,666 effective horse-power, and the cost of the gasholders is £6 per effective horse-power, reckoned on the average rate of supply throughout the year. Here, allowing 10 per cent for interest and depreciation, the storage adds about 12s. per effective horse power to the annual cost.

Accumulator or Battery Storage.—The electrical engineer would be glad to have a means of storage equivalent to a gasholder. For a time it was thought that such an equivalent had been found in the storage battery. The use of such batteries is limited to continuous current systems, and they have besides the practical defects (1) that the maximum rate of discharge is limited, and (2) that about one fifth of the energy stored is wasted. Nevertheless, they would have been an extremely important factor in electric central station working but for their excessive cost. With a 24 hour load line, such as that of most electric lighting stations, the amount of storage required to enable the generators to work at a uniform rate may be defined thus: the battery must be capable of supplying energy at a rate equal to three times the mean rate of supply for the 24 hours. Also, it must be capable of storing during one part of the 24 hours, and restoring in the other about half the whole supply for the 24 hours.

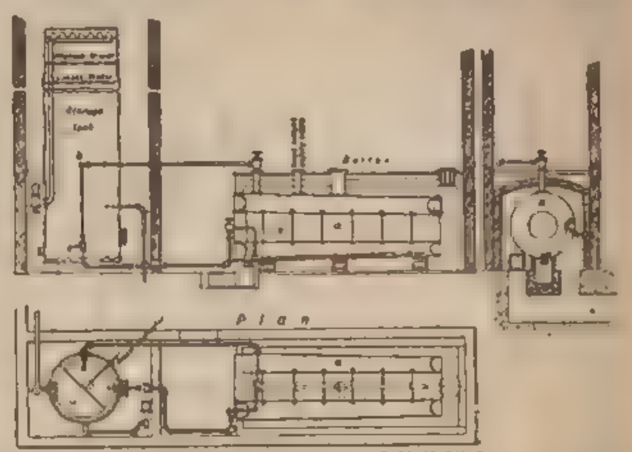
The cost of storage batteries prohibits their employment on this scale in large stations. Employed in a limited way, they serve some useful ends. In some stations they supply the energy required for 10 to 13 hours out of the 24, during which time the engines are stopped. They diminish the fluctuation of load of the engines during the time in which they are running, storing energy not required in the external circuit. But they do not obviate the necessity for having a varying number of engines at work. Prof. Kennedy puts the case well when he says that they enable the station to be shut down for some hours and act as flywheels, smoothing the irregularities of supply.

* *Howard* Lectures delivered before the Society of Arts.

Cost of Accumulator Batteries. From data given me by Prof. Ayrton, it appears that eight Epstein cells, tested in the laboratory, would work at 1 h.p., and store a charge for 2½ horse power hours. The cells cost, without allowance for buildings, insulation, or switching arrangements, or for waste of energy, £20. That is, the bare cost of the cells amounts to £20 per horse-power reckoned on the maximum rate of working, or to £8 per horse power hour stored. Suppose a station working at an average of 500 h.p. The maximum demand in the 24 hours would be 2,000 h.p., of which 1,500 would have to be supplied from the battery. The cost of the battery to supply energy at the necessary rate would be £30,000. During 24 hours the quantity of energy supplied would be 12,000 horse-power hours, half of which must be stored. Batteries of sufficient capacity would cost £48,000. Here the latter condition determines the cost. Taking interest at 5 per cent., and maintenance and depreciation at 12½ per cent., the annual cost of the battery would be £8,400, or nearly £17 per horse power of average rate of working of the station. This is the bare cost of the cells without buildings, adjuncts, or reserves.

In a project for lighting Frankfort-on-Main, Mr. Oskar von Miller and Mr. Lindley provided large secondary battery stations. The batteries had a capacity of 11,700 ampere-hours, and were capable of supplying a current of 3,500 amperes at 100 volts. The batteries, with wood platforms, insulation, etc., were taken to cost £25,100, and the buildings for them £11,600. This is equivalent to a capital cost of £23 per horse-power hour of storage capacity, or £78 per horse power power reckoned on the maximum rate working.

Thermal Storage.—Secondary batteries, being too costly as a means of storage, except on a very limited scale, the question arises, is any other means of storage available in conjunction with steam-engines? Some means of hydraulic storage will be considered later; such means are rarely applicable for the storage of steam power. Lately, Mr. Druitt Halpin has proposed a system of thermal storage which appears, in many respects, to meet the conditions required. Energy is first obtained in steam-power stations in the form of heat. Can the heat be directly



THERMAL STORAGE BOILERS AND STORAGE TANKS

FIG. 10.

stored? Heat is a very unprisonable form of energy, escaping through all bodies and in all directions. But, in New York, steam is transmitted through miles of pipes, and, by reasonable jacketing, the loss of heat is reduced to a moderate percentage of that carried. In a properly constructed storehouse for heat with reservoirs, closely packed and presenting little external surface, the radiation loss need not be large. For storage, heat must be imparted to a material body of large heat capacity. It is easily given to water in boilers of ordinary construction. A body of water, highly heated, in a well insulated chamber, will store a large quantity of heat. To permit the water to be heated it must be kept under the pressure corresponding to its temperature. The task of storing a mass of heated water presents no mechanical or physical difficulty. It is a condition of any system of heat storage for central stations that the energy stored should be recoverable whenever and at any rate of supply required. Heated water fulfils the condition. If the pressure is reduced steam is generated instantly and in controllable amount. The steam generated can be used in the engines to generate mechanical energy as it is wanted.

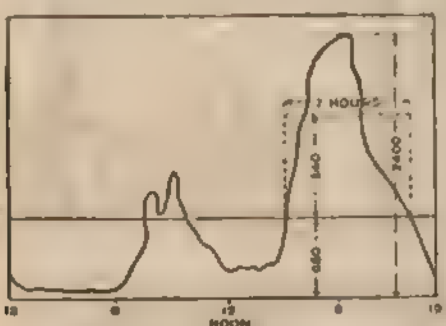
Mr. Halpin's plan is, therefore, to communicate heat in boilers to a body of water. The heated water is stored in reservoirs under pressure. From the reservoirs steam is taken through a pressure-reducing valve exactly when and in what quantity it is required. Mr. Halpin proposes that the heat reservoirs should be under a pressure of 265lb. per square inch (absolute) when fully charged, the corresponding temperature being 406deg. F. He proposes that the steam engines should be worked at 130lb. per square inch, corresponding to 347deg. F. The total heat stored when the reservoirs are fully charged is the difference of the total heat of the water at 406deg. and 347deg. F., or the heat due to a range of temperature of 59deg. Every pound of water falling in temperature through that range will yield 61 thermal units of heat. But the total heat required to generate a pound of steam at 130lb. per square inch from water at 347deg. is 868·8 thermal units. Consequently 14¼lb. of water falling in temperature from 407deg. to 347deg. will yield a pound of steam.

To allow for radiation, loss, and imperfect working, this may be taken at 16lb. of water per pound of steam. A simple cylindrical reservoir, 8ft. in diameter and 30ft. long, will contain 84 000lb of heated water. Such a reservoir would be capable of generating, under the conditions supposed, 5,250lb of steam at 130lb per square inch. The steam consumption may be taken to be, per effective horse power, 18lb. per hour in condensing and 25lb. in non condensing engines. Hence one such reservoir would store 286 effective horse power hours if the steam is used in condensing engines, or 210 effective horse power hours if the steam is used in non-condensing engines. If the reservoir were fully charged and discharged daily it would yield 104,400 and 76,660 effective horse-power hours of stored energy yearly in the two cases. A reservoir, 30ft. by 8ft., would cost, erected, with ample allowance for buildings and appendages, £470. As it is not exposed to fire, its deterioration would not be considerable, and 10 per cent. would be sufficient to cover interest, maintenance, and depreciation. Hence, the first cost of such reservoirs, reckoned on their storage capacity, and the annual cost per horse power added to stored energy by the cost of storage, would be as follows :

—	Cost of reservoirs per effective horse-power hour of storage capacity.	Annual cost of storage per horse power supplied from reservoirs.
Condensing plant . ..	£1·64	£3·94
Non-condensing plant	2·24	5·37

The cost in the last column is the cost due to 8,760 effective horse-power hours annually.

Mr Halpin's plans appear to be practicable and to promise considerable economy in stations where the load fluctuates greatly, but they are untried, and it would not be fair to omit to point out that there are details of working involving difficulties which must be met. The cost of the mean annual horse power supplied is not inconsiderable, but it is not prohibitive. The waste in irregularly working stations is so large that *primâ facie* it may be assumed that there is economy in storage on Mr. Halpin's system



TYPICAL DIAGRAM 2600 H P STATION

Fig. 11.

But it must be remembered that this system attacks the boiler waste only and leaves the engine waste due to varying load untouched To a certain extent the latter losses can be mitigated by the sub-division of the engines.

Arrangement of Thermal Storage Reservoirs on Mr. Halpin's Plan. – It is possible that the best way of working thermal storage tanks is not yet known, but one arrangement proposed is shown in Fig. 10. The steam-boiler, *a*, is completely filled with water, the storage tank, *b*, nearly so. The two are in free communication by a system of circulating pipes. There is an ordinary feed-pump supplying water direct to the boiler or the storage tank. But instead of keeping the water in the boiler at a nearly constant level, the level in the storage tank is kept nearly constant. In addition, there is a circulating pump maintaining a rapid current of water from the boiler to the storage tank, and, consequently, back from the storage tank to the boiler. Water heated in the boiler is constantly being sent to the storage tank, and water cooled by disengagement of steam is returning to the boiler. The steam spaces of the tanks are all in communication. The pressure there will be the steam pressure due to the hottest tank. The steam required is taken off through a reducing valve. It will then be generally dry, or slightly superheated, in consequence of wiredrawing, which is advantageous for the efficiency of the engines. In a station with thermal storage tanks, the boilers will be of a size sufficient to supply the mean demand for steam on the day during the year when the demand is greatest. The boilers will be worked continuously at a nearly uniform rate, like a bank of gas-retorts. The heat not required in hours of small demand will be stored in the tanks. The excess of heat required to generate steam in hours of great demand will be taken from the store in the tanks.

Example of a Station Worked in the Ordinary Way and with Thermal Storage Tanks. The example in Fig. 11 has been worked out by Mr. Halpin. He takes a case of an electric lighting station where with the normal mid winter load the daily output is 15,600 effective horse power hours, or the mean rate of working 650 effective horse power. In ordinary conditions, without storage, engines and boilers capable of working to 2,400 h.p. would be required during the short period of maximum demand. With thermal storage tanks the boilers would be of 650 h.p. only, but, on the other hand, thermal storage tanks must be provided capable of generating all the steam required in excess of 658 h.p. when the demand exceeds that amount. An examination of the load curve shows that 5,900 effective horse-power hours would meet the whole demand in excess of the mean demand. Taking 16lb. of heated water to supply 1lb. of steam, 360lb. of water stored would generate steam enough for an effective horse power hour. Then the storage tanks must contain 900 tons of water; 24 tanks, 30ft. by 8ft., would have sufficient capacity. Without storage tanks: Eight boilers, each with 2,000 square feet of heating surface and two boilers in reserve. Cost of 10 boilers, with erection, pipes, and pumps, £10,300. With storage tanks: Two similar boilers and one in reserve, and 24 thermal storage tanks. Cost of three boilers and 24 tanks, with erection, pipes, pumps, etc., £15,000.

The cost of the plant is greater with the storage tanks by £4,700. Taking interest and depreciation at 10 per cent., this would correspond to an annual charge of £470, or about the value of 470 tons of coal at London price. But if the saving of waste by having boilers regularly, instead of irregularly, worked were only $\frac{1}{4}$lb. per effective horse-power hour, the annual saving of coal would be 1,270 tons.

Cases still more favourable for the application of the thermal storage system are those where heat is now absolutely thrown away The destructor for ash bin refuse, which has already been described, must be worked continuously day and night. This makes it difficult to utilise the heat. But with thermal storage tanks the heat might be captured and stored for use at hours when mechanical work had to be done. In such a case the advantage of thermal storage would seem to be very great. One other similar case has been thought of by Mr. Halpin. In the production of lighting gas, about 312lb. of coke are burned per ton of coal carbonised The heat in these products of combustion is now entirely thrown away. If they were taken through the flues of a boiler they might be reduced to 600deg. before escaping They would furnish about 759lb. of steam per ton of coal carbonised, or about 25 effective horse power hours.

Water Power.

Where there exists a natural waterfall, with a considerable and regular flow, and where local conditions are favourable for the construction of the necessary works, water power is generally cheaper than steam power The water costs little or nothing; the cost of maintenance of hydraulic machinery and the cost of superintendence are small; the power is regular, controllable, and convenient. In such cases, the annual cost of the power consists almost entirely of interest charges on the capital expended in works and machinery. With some exceptions, water power is at present utilised in the neighbourhood of a natural waterfall. The usual means of transferring the power of the fall adopted, till a recent period, has been the conveyance of the water itself in canals and pipes. In some cases water has been thus conveyed for hydraulic mining and manufacturing purposes very considerable distances. But a more convenient and cheaper means of transmission would greatly increase the availability of water power, and the relative importance of steam power and water power would, in some countries, be very considerably changed

It appears from a report by Mr. Weissenbach that in 1876 70,000 h.p. derived from waterfalls were applied in manufacturing in Switzerland. Probably the amount now employed is at least 80,000 h.p. It is estimated that the total available water power in Switzerland amounts to 582,000 h p. Putting the annual value of a horse-power at £6, this represents an annual value of £3,500,000. Used to replace steam power it would save annually 1,250,000 tons of coal. It is stated that at the present time Switzerland pays £800,000 annually to other countries for coal.* Nearly the whole of this expenditure could be saved if its natural wealth of water power was utilised. The recognition of the importance of this supply of power is exciting great interest in Switzerland, and there is hardly an important factory which is not either using water power or making preparations or surveys with a view of doing so.

The utilisation of water power often involves the construction of large permanent works, such as river dams, reservoirs, and canals. Mr. Emery estimates that at Lawrence, in the United States, £200,000 was spent on works, independent of the hydraulic machinery, and at Lowell a still larger sum.† Such extensive works can be best executed by an association in the interest of many consumers. Thus is created a water power company, who establish what is virtually a central water power station and a distribution of power at a rental to consumers. In the American cases, as already stated, the water itself is distributed in canals to consumers at a level permitting the creation of a waterfall at the mill or factory. But in certain other cases a further step was taken. the water power company utilised a natural fall and erected the necessary turbines, and then transmitted the power in the form of mechanical energy to consumers. Installations of such a kind, now of a quite respectable antiquity, were erected at Schaffhausen, Freiberg, Zurich, and Bellegarde. In these cases the means of transmitting power adopted, admirable as it was, had limitations and the extension of the works was restricted. Now that there are new means of transmission, the Schaffhausen and Zurich power generating stations are being increased, and a new and remarkable installation has been erected at Geneva.

(To be continued.)

* Reifer. Berechnung der Turbinen.

BUSINESS NOTES.

Dover.—The establishment of Messrs. Chitty is to be provided with electric light.

Wirral.—A telephone is to be provided by the Board of Guardians for the workhouse.

Great Northern Telegraph Company.—The receipts during September amounted to £23,600.

Copper.—The price of copper in Newcastle varies from £46. 10s. to £46. 17s. 6d. for tough copper.

Bath.—The Watch Committee have complained of the failure of the electric light on certain evenings.

Western and Brazilian Telegraph Company.—The receipts for the week ended October 6 were £3,435.

St. Olave's (London).—The new offices of the Board of Works in Vine street are to be lighted by electricity.

Paisley.—The question of lighting Hawkhead Asylum is under the consideration of the District Lunacy Board.

Greenock.—Messrs. J. and R. Houston, engineers, of Greenock, have just fitted up their works with the electric light.

Belfast.—A site for the station has been chosen, and the specifications and plans are being prepared by Prof. Kennedy.

Grimsby.—A sub committee of the Town Council is to be appointed for the purpose of promoting a provisional order.

Chesterfield.—The Town Council has given the National Telephone Company notice to remove all posts from the streets.

Hammersmith.—The Vestry is negotiating for the supply of electric light to the shopkeepers and public buildings in the parish.

Blackpool.—The question of the electrical *fête*, which commences to-day, was discussed at a meeting of the Town Council last week.

Bedford.—The Town Council have resolved to transfer the powers contained in their provisional order to the Bedford Electric Light Company, Limited.

New Business.—Mr. N. F. Nalder has started business as a maker and repairer of all kinds of electrical instruments at 8 and 10, Charing Cross-road, W.C.

Glasgow.—The Town Council have agreed to increase the salary of Mr. William Arnot, the electrical engineer of the Corporation, from £250 to £350 per annum.

Richmond (Surrey).—Allotment letters have been issued by the Richmond (Surrey) Electric Light and Power Company, Limited, of 4, Sun-court, Cornhill, E.C.

Liverpool Overhead Railway.—The secretary, in reference to the issue of 2,500 preference shares, states that letters of allotment and regret have been posted.

Heywood.—The Local Government Board have sanctioned the borrowing by the Heywood authorities of £3,500 for machinery and electric lighting at the sewage works.

Submarine Cables Trust.—On and after the 16th inst., the sum of £1. 15s., on account of the coupon due on the 15th inst., will be paid by Messrs. Glyn, Mills, and Co.

Whitby.—The question of obtaining an electric fire alarm has been referred to the Fire Committee of the Local Board, who will meet and examine the tenders which have been received.

Stockport.—Mr. W. Lees said at a meeting of the Town Council last week that in the future the town would have to undertake considerable expenditure in the matter of electric lighting.

Burnley.—At a meeting of the Town Council last week Councillor Williams asked for some explanation as to the transformer to be purchased at a cost of £200 for the electric lighting station.

Aberdeen.—The Gas Committee of the Town Council have accepted the tender of Messrs. Crompton and Co., Limited, to supply copper connections for the electric mains at 1s. 1d. and 8d. per pound.

Admiralty List.—Messrs. Paterson and Cooper have been placed on the Admiralty list for dynamos. The firm have for several years been on the list for general fittings, and have recently completed a large order.

Dover.—The Council have been recommended to adopt the memorandum and articles of association of the Dover Electric Supply Company, Limited. A site has been chosen for the station on the Tennis Club grounds.

Bournemouth.—The Town Council have resolved to apply to the Local Government Board for power to borrow £200 to provide a means of communication between members of the volunteer fire brigade, as agreed upon previously by the Council.

Edison Swan Lamps.—The Edison and Swan United Electric Light Company, Limited, announce that a reduction has also been made in the price of their extra special lamps of from 32 c.p. to 100 c.p. Particulars are given in our advertisement columns.

South Shields.—The Town Council have received 49 applications for the post of electrical engineer to the Corporation, and the following selected from the number: John Christie, Glasgow; S. V. Gilham, Newcastle; Joseph A. Jeckell, Norwich; and W. Howard Tasker, London. Mr. Jeckell has been appointed by 15 votes to 10.

St. Neots.—An application of Messrs. Jordan and Addington for permission to erect telephone wires across certain streets to Eynesbury and the railway station has been referred to a committee of the St. Neots Local Board to report to the next monthly meeting.

Direct United States Cable Company.—The Directors have resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income tax, being at the rate of 3½ per cent. per annum for the quarter ending September 30, payable on and after the 24th inst.

City and South London Railway Company.—The receipts for the week ending October 8 were £813, against £859 for the same period last year, or a decrease of £46. The total receipts for the second half year of 1893 show an increase of £409 over those for the corresponding period of 1892.

Islington.—A deputation of the Islington Labour League have suggested to the Vestry that if the installation of the electric light in the parish should be decided on, the contracts should contain a clause stipulating that workmen living in the district should be given preference of employment.

St. Pancras.—The Vestry invite tenders by the 16th inst. for the building of a chimney shaft at East St. Pancras Station, King's-road, N.W. The Vestry has accepted the tender of Messrs. E. Houghton and Son, of Stroud Green, at £1,876. 4s., for the extension of the Regent's Park central station.

Rotherhithe.—Mr. Thomas, the surveyor of pavements, reported at a meeting of the Vestry last week that the London Electric Lighting Company had taken up several footpaths in the parish, but had failed to reinstate them properly. The clerk was instructed to write to the company on the matter.

Lambeth.—Mr. Honey reported at a meeting of the churchwardens and overseers that the City and South London Railway had recently very much improved as a property. Its traffic was increasing day by day, and he thought the time had arrived when it should be revalued for the purpose of assessment.

Telephony.—A telephone wire has just been completed between Inverness and Foyers, with connections to Whitebridge and Gorthlick. The Post Office authorities have made arrangements for the receipt and delivery of telegrams at their offices in the district. Messages will be telephoned to and from Inverness.

Chiswick.—Mr. Waters enquired at a meeting of the Local Board last week, if there was any further movement with regard to the provision of the electric light in the district. Mr. Ramsden stated that he had arranged to make an appointment with Mr. Grant as soon as that gentleman came back from his holidays.

Portsmouth.—The Electric Lighting Committee of the Town Council have submitted a certificate from Messrs. Waller and Manville for payment to the contractor for the erection of the electric lighting station in Gunwharf-road of the sum of £600, and recommended that the amount be paid. This recommendation has been adopted.

Leamington.—The Telephone Sub Committee of the Town Council have been in communication with the National Telephone Company, and they have recommended that the cost should be ascertained of the Council's putting down its own telephone plant for communication between its various public offices. This recommendation has been approved.

Appointment Open.—A thoroughly practical man is required as foreman of gas and electrical fitters. Must be capable of estimating and superintending the carrying out of both electric and gas work. Age not to exceed 35. Wages £3 per week. Applications are to be sent to the Manager, Gas Fittings Company, Limited, 126, Duke street, Liverpool.

Battersea Polytechnic Institute.—The following appointments are now open: Lecturer in technical electricity, salary £250; assistant lecturer in mechanical engineering, salary £150; engineer to have charge of electric lighting and heating and assist in workshop. Full particulars on application to the secretary of the Battersea Polytechnic Institute, S.W.

Tenders Wanted for Cardiff.—Tenders are required by not later than the 16th inst. by the Cardiff Corporation for the supply of electric light cables, and for drawing in certain portions and making all necessary joints. Particulars may be obtained on application to the borough engineer at Cardiff, or of Mr. W. H. Massey, 25, Queen Anne's-gate, Westminster.

West Derby.—On the occasion of the starting of the new refuse destructor at the works of the Local Board on Tuesday, Mr. F. C. Everett (the surveyor) said that while useful for completely destroying the rubbish of the district, the heat from the destructor might be utilised for the heating of baths and washhouses, or for generating power to light the district by electricity.

Llandrindod Wells.—A discussion has taken place at a meeting of the Local Board on the subject of introducing the electric light to the district, and the Clerk gave an account of the system adopted at Dolgelley, North Wales, where he had lately seen it in operation. It was generally considered very desirable that steps should be taken to introduce the system, if possible.

Dundee.—The demand for installations of the electric light has been steadily increasing in Dundee since the works were completed. Of the 6,000 lamps which the present plant can supply, as many as 4,000 have been applied for and are now being supplied, and it is expected that the remaining 2,000 will also be in use very soon. The Gas Commission have considered the question of lighting the old steeple tower by electricity. The Works Committee is to report on the matter.

Omnibus and Tramcar Electric Lighting Company, Limited. This Company has been registered with a capital of £60,000 in £5 shares to acquire the business of the Universal Electric Lighting Company, and to carry on and extend it. Signatories to the memorandum of association are: A. W. Stormont, A. L. B. Kerr, W. J. Griffiths, J. F. Rogers, J. A. Lloyd, H. H. Clayson, R. Wolfenden.

Hanley.—The members of the committee who have been entrusted with the work of preparing for lighting Hanley by electricity are manifesting great activity. The footpaths and crossings in many of the central streets have been taken up, and the cables have been laid down. The positions of the transformer chambers have been agreed upon, and the localities have been selected for the arc lamps to be used.

Tenders for Aberdeen.—Tenders are invited by the 25th inst. for supplying boiler, engine, dynamo, and other electrical plant for the Northern Co-operative Company's central premises. Specifications may be obtained from the secretary, 54, Loch-street, Aberdeen. A charge of £1 will be made for copy of specification, and will be returned on a *bonâ fide* tender being received. Tenders to be marked "Tender for Electrical Plant."

Keighley.—The annual report of the gas engineer to the Town Council, presented at a meeting of the latter, referred to the question of electric lighting at considerable length. It was mentioned that arrangements were being made to inspect the installations at Leeds, Bradford, Morecambe, and in other towns. It was estimated that the cost of a plant to supply the principal streets in Keighley would be from £15,000 to £20,000.

Halifax.—At the Drill Hall on Monday a trades and industrial exhibition was opened. The hall has been tastefully decorated by Mr. E. Booth, of Southgate, and the electric light is supplied by the Halifax Mutual Electric Company. Three arc lights, each of 2,000 c.p., are suspended from the roof, and a lamp of like power hangs over the Prescott-street entrance, while outside upon the roof there is a revolving search light of 10,000 c.p.

Leeds.—In anticipation of the tramways of the city being transferred from the Tramways Company to the Corporation, the Highways Committee are now considering what improvements shall be made in the system. The demonstration of the utility of electricity as a motive given on the Roundhay Park Tramway has made a favourable impression in the community. The Highways Committee have arranged to visit Walsall and Darlaston for the purpose of inspecting the system and judging whether it would be suitable for Leeds.

Coventry.—One of the principal additions to business premises is the fine and original block of buildings in High-street erected by the Coventry Gas Fittings Company. The right hand window as one enters the building will be used for exhibiting three Otto gas engines by Messrs. Crossley, of Openshaw, Manchester. One will be used for driving a dynamo for lighting the premises by electricity, a second will work a hoist erected at the rear to convey goods to either floor, and the third will simply be for exhibition, though also in motion.

British Volta Glow Lamp.—The prospectus is being circulated of the British Volta Electric Glow Lamp Company, Limited, whose capital is £2,000, in 2,000 shares of £1 each, of which 1,600 are now offered for public subscription. The balance of 400 shares is issued to the vendors, fully paid up, in payment for patents, etc. This company is formed to acquire, work, and develop a provisional patent for improvements in electric incandescent lamps, and other processes in connection with their manufacture, to establish lamp factory, and to supply incandescent lamps.

Tenders for Manchester.—Tenders are invited for supplying and fixing electrical plant, vertical engine, dynamos, accumulators, and all necessary connections and appliances required to light the sewage works at Davyhulme, for the Rivers Committee. Copy of specification and all particulars may be obtained on application to Mr. John Allison, city surveyor, Town Hall, Manchester, on deposit of £1. 1s., which will be returned on receipt of a *bonâ fide* tender. Tenders to be addressed to the chairman of the Rivers Committee, endorsed "Tender for Electrical Plant, Davyhulme," and delivered at above office by 17th inst.

Redruth.—The electric light is gradually increasing in favour at Redruth. Messrs. Beringer and Schwerer, jewellers, have adopted it, and the illumination is greatly admired. In the basement a small Tangye gas engine drives a dynamo designed by Mr. E. W. Tangye, and the current generated supplies 11 incandescent lamps, which give a total of 200 c.p. The engine consumes about 40 cubic feet per hour, which it is estimated will compare very favourably with gas lighting, besides the further advantage of the goods not being injuriously affected by the light. The plant at Messrs. Beringer's was installed by Mr. E. W. Tangye.

Newcastle.—The Town Moor Management Committee of the Newcastle Corporation met the other day. The question of the fountain and electric light, which the Council at its last meeting decided to set up in the Leazes Park, was discussed, and the city engineer was instructed to get tenders for the work immediately for the fountain and lamp, in order that the light might be ready for the skating in winter. At a meeting of the Town Council, Mr. A. Hepburn moved the appointment of a committee to consider the question of the Corporation providing the electric light in Newcastle. Mr. J. Barker Ellis seconded the motion, which was carried.

Sunderland.—At a special meeting of the Highways Committee of the Corporation, the borough surveyor reported the receipt of further specifications from Prof. Kennedy, enabling him, after conferring with the professor a little more as to some details, to advertise for tenders for laying the outdoor plant. There will be three contracts to let—one for cutting the roads and making culverts so as to carry the wires underground, one for metal pipes and castings, and one for stoneware pipes and insulators. It was agreed that the borough surveyor should confer with Prof. Kennedy on the points he wanted explaining, and that he then should be left to advertise for the tenders.

Brazilian Submarine Telegraph Company.—The report of this Company for the half year ended June 30, shows that the revenue amounted to £106,859, and the expenses to £40,580. After providing for debenture interest, sinking funds, and income tax, there remains a balance added to the amount brought forward of £56,043. A quarterly interim dividend has been paid, and £7,000 transferred to reserve, increasing that fund to £638,675. The Directors recommend a final dividend of 3s. per share, making 6 per cent. for the year, and a bonus of 1s. per share, both tax free, leaving a balance of £3,533 to be carried forward. The dividend and bonus will be payable on the 19th inst.

Monmouth.—With reference to the schemes sent in for competition for the drainage of the town, the Mayor stated at a meeting of the Council last week that the plans had been sent to Mr. Lailey, civil engineer, and he would select the best two schemes towards the end of the week. He had received a letter from the Brush Electrical Engineering Company, stating that they would prepare all the necessary plans required by the Local Government Board to be presented at their meeting and would also attend the meeting, when it took place, free of charge. As soon they got the plans they would no doubt appoint an enquiry here. The question was rather an important one as to whether it was advisable to employ a barrister to give them his help at the enquiry. On the proposition of Alderman Hyam, seconded by Councillor Breakwell, it was decided that a barrister should be retained. The town clerk was instructed to take the necessary steps to obtain a provisional order for electric lighting.

Edinburgh.—The Lord Provost proposed at a meeting of the Town Council on Tuesday that Mr. Mackenzie should make an interim report in regard to what he had done regarding the purchase of a site for an electric light station. He might say that they hoped to be able to supply the electric light about the end of next year, and people who wished the light should be beginning to get their houses wired. Mr. Auldjo Jamieson objected to an interim report being made on this subject, when information was denied on another and more pressing question at an earlier part of the meeting. Mr. Mackenzie then made his interim report, the effect of which was that he had been able to purchase a site for an electric station at Dewar place, at a cost of £7,322 and that the site had the approval of Prof. Kennedy, their advising engineer. The purchase was approved of, and the chamberlain authorised to pay the money. On the proposal of Mr. C. S. Brown, it was agreed that Prof. Kennedy's report should now be circulated.

Contract Dispute.—At the Cardiff County Court last week, before Judge Owen, Messrs. J. B. Sanders and Co., electrical engineers, brought an action against Mr. J. H. Insole, of Ely Court, to recover £23. 2s. 9d. The claim was £17 for laying gas pipes from the main to within Mr. Insole's premises to the gas engine which was laid down by the plaintiffs for the purpose of driving a dynamo. A contract was put in in which the plaintiffs undertook to supply all necessary plant for giving Mr. Insole an electric installation of 75 lights of 16 c.p. for £950. This sum had been paid, together with other moneys for extras admitted by Mr. Insole. On the claim £4 was paid into court for some of those extras which had been overlooked. The remaining part of the claim was £4 for a voltmeter and £16 for the gas mains. His Honour was of opinion that the mains and the meter were necessary for a complete installation, and were covered by the contract. He gave judgment for the plaintiffs for the amount paid into court, and ordered them to pay defendant's costs from the time the moneys had been paid in.

Lynton.—A special meeting of the Lynton Local Board has been held (Mr. Heywood presiding) to consider Mr. Benn's proposal to dispose of the electric lighting works to the Board for a rental of £193 per annum. A letter was read from Mr. Evan B. Jeune, stating that in a general way he was in favour of local authorities having control of lighting. In the present case he could not say that he had had time to form a definite opinion. If (1) the agreements made with Mr. Benn were of a favourable nature towards the supply of electric light; (2) the machinery efficient for the amount of light now in use; (3) there was no probability of any great outlay for renewal or repair of machinery at an early date; (4) the present revenue equals or exceeds the expenditure; and (5) that an agreement to manage for not less than three years, renewable afterwards from year to year, be made with some duly qualified person, recommended by an electrical engineer, he (Mr. Jeune) would be in favour of taking over the works. He considered the time given was short, more especially as members of the Board were not experts, and had no outside expert to rely on. The letter also stated that Miss Lock-Roe would not consent to more water being taken from the Lyn than at present. After considerable discussion it was resolved that a meeting of the ratepayers should be held to consider the advisability of acquiring the electric light works.

Newport (Mon.).—Alderman Davis proposed at a meeting of the Town Council this week, that application should be made to the Local Government Board for sanction to the borrowing of £28,000, under the powers of the Electric Lighting Act, 1882, repayable in 30 years, for the purpose of providing a supply of electricity in the borough. This proposition was seconded and carried. The Electric Lighting Sub-Committee of the Parliamentary Committee reported

that they had received the preliminary report of Mr. Robert Hammond, the electrical engineer, upon the proposed installation of electricity works, and it was laid on the table for the information of the committee. The proposed site selected for the central station is upon land in Friars Fields, entered from Union court, and Mr. Hammond considers it most advantageous in many respects, more especially as it will be easy to obtain a siding from the railway across Canal parade running into the yard for the supply of coal. The estimated expenditure, including the mains and arc lighting, of the installation for the western district of the borough, is £25,000. The report had been considered by the sub-committee, and some modifications in the proposals suggested. In the meantime it is recommended that the sub-committee should be authorised to request Mr. Hammond to proceed with the preparation of the detailed plans and specifications, in order that tenders may be obtained at the earliest possible date. The report was adopted.

Rochdale. – On the minutes of the Health Committee submitted to the Town Council last week, Councillor Diggle asked the chairman whether the committee were satisfied with the installation of electric light at the sanitary works, and whether their engine power was large enough to provide electricity for the Town Hall and neighbouring premises. Councillor Hardman replied that the plant had worked without a hitch. The supply was constant and regular, and satisfactory in every way. As to whether their power was sufficient for the suggested extension, he should like to know what the "other premises" were before committing himself. They had quite enough power for supplying the large hall, so far as the engine was concerned. Councillor Diggle said he had the Technical School particularly in mind. The other evening there were 75 gas lights burning in the chemical laboratory, and in spite of the ventilation system the room was as hot as a stove. It would be to the interest of the Corporation to supply both the Technical School and the Town Hall with electric light. They had spent a good deal of money in decorating the hall, and it would be a pity to spoil the room with gas. Councillor Cunliffe agreed as to the desirability of using electricity for lighting not only the assembly-room of the hall, but also the offices, where a large number of clerks were at work. The patent for incandescent lamps would expire in November, and already they were offered to users at less than half the former price. Electric light in the Town Hall would be a decided boon. The Mayor reminded the Council that they came to a decision on this matter a short time ago, and that there was nothing in the minutes to justify its reintroduction now. The minutes were confirmed.

Bristol. —When the adoption of the general district rate was discussed by the Town Council a few days ago Councillor Pearson said with regard to the electric light the machinery was for 100 arc lights only, and 96 had been put up. The incandescent lights were to be 10,000 16 c.p. lamps. Now it was evident that the street lighting could not be extended at present, and they could not go to Bedminster, for example, without putting a sub-station there for transforming. Certain slight extensions had already been granted. With regard to the incandescent lamps, it was calculated that only 60 per cent. of the lamps were alight at the same time in residential districts, so that there was some room for extension; but in Bristol the area to be lighted was a shoppy one, and therefore the number of lamps in use at the same time would be greater than in a residential district. Councillor Ashman said Mr. Pearson's answer was not at all satisfactory. They were told, when this matter was before them two years ago, that this was the first installation, and that cables would be carried to the bottom of Union street and the Croft as soon as possible; but they must be surprised to learn for the first time that this was impossible in regard to extending the light to Bristol North, and that if Bedminster needed the light they would have to have a station there. Councillor Pearson said Mr. Ashman quite misunderstood him. If they needed the light in Bedminster it would have to be transformed at a sub-station there, and delivered to the houses. If the demand for the light increased, they would have to enlarge their works at Temple-backs. They had now certain power at that station, and if more was needed they would have, as in other such undertaking, to extend their works.

Whitehaven. The minutes of the Electric Lighting Committee of the Town and Harbour Trust, presented at a meeting last week, included the following: "11th September. Read correspondence between surveyor and Dr. Hopkinson. The surveyor submitted account which he had received from the Furness Railway Company for expenses incurred by them in providing a special watchman while the electric cables were being laid under the Coach road level crossing. The committee do not admit any liability for the same. The surveyor reported on the progress of domestic lighting. 18th September. The surveyor was instructed to make arrangements for laying cables to Messrs. Pattinson and Winter's works, Barracks road, by way of Scotch street and Irish-street. The clerk was instructed to write to the Lowca Engineering Company, Limited, calling their attention to sundry defects in the new boilers, and requesting them to remedy such defects, otherwise the committee would be obliged to take steps under the powers of the contract." The Chairman moved the confirmation of the Electric Lighting Committee's minute. With regard to the lighting of the harbour, the mains were all laid and everything was ready, except that they were kept waiting for lamp fittings, which had not yet come to hand, for some unaccountable reason. It was to be hoped that within the next week they would be here, and the work would be so far finished that they would be able to turn the current on to the harbour. Mr. Hastwell seconded the motion, which was agreed to. The seal of the Board was affixed to a bond for £300 lent by a private individual for six years at 3½ per cent., this taking the place of a like amount of bonds at present held by the Cumberland Union Bank at 4 per cent.

Grimsby. –A meeting of the Electric Lighting Committee of the Town Council was held last week, Alderman Palmer occupying the chair. The members of the committee were each supplied with information respecting the cost of the electric light as introduced in many large towns. The report had been compiled by the borough surveyor (Mr. M. Petree) at the request of the committee. At Bradford there were 22 miles of mains for the electric light, and the whole cost £40,750. The current was sold at 5d. per unit, and the motive power cost 4½d. per B.T. unit. In Hull the cost of the works was £3,000, and the driving machinery £4,060, mains £10,000 (for 1¾ miles first laid). The charge was 7d. per unit, and motive power 6d. per B.T. unit. Mr. Nutt noticed that Scarborough had been omitted from the list of towns. Anyone who had visited it must have noticed the large amount of electric light in use for lighting private and public shops. At the hotel he stayed at this summer, whilst at Scarborough, the proprietor, in answer to questions, said that the cost was treble that of gas. The borough surveyor pointed out that in the case of St. Pancras the cost was three times that of gas, but the illuminating power was 10 times as great as gas. In a town of 32,000 inhabitants where the electric light had been adopted, the cost was greater than gas, but this was compensated for by better lighting. The Chairman moved that the committee recommend the Council to apply for a provisional order as a protection against electric lighting companies coming into the town and obtaining a monopoly. The resolution also was to appoint a sub-committee to go fully into the matter and get estimates from one or two contractors, so as to gain an idea as to the probable cost of the thing. He pointed out that if they got a provisional order they need not be compelled to carry out an electric lighting scheme if they did not see fit to do so. This proposition was duly seconded and carried.

Cardiff. –At a meeting of the Cardiff County Council on Monday Mr. H. White again called attention to the defective supply of gas and defective burners. He asked whether anything had yet been done in the matter. The Mayor said he was sorry to tell them they could not come to any arrangement with the gas company. Mr. White proposed that the Lighting Committee be asked to furnish a detailed report of the present situation of things, so far as the respective rights and responsibilities of the Corporation and the company were concerned, which should be furnished to individual members of the Corporation. Alderman R. Cory seconded the resolution, and said if the gas company would not treat them with courtesy and civility let them go to Parliament for powers. Mr. W. Lewis asked when the electric light would be supplied to the town. The Mayor said it might be in about 10 years' time, but it would be a very expensive thing. They were now supplying a limited area, which would come into operation in March next. This, however, was only intended for street-lighting. To supply all the streets and lanes would be a very expensive affair. As he argued four or five years ago, they ought to have purchased the gasworks, and if they had done so when they had the chance they would now be saving about £3,000 a year to the rates. He, however, was opposed by some people, and this was how the thing turned out. Electricity was a better light, but they could not do without gas. The minutes of the committee were then confirmed. At Cardiff County Council on Monday, the Town Clerk reported as to the proposed agreement between the National Telephone Company and the Post Office, and Alderman Carey stated that the Glasgow Corporation had applied for power to establish a municipal telephone system. He suggested that they should write for a copy of the Glasgow Bill, and if it was thought advisable they could apply for similar powers. On the Continent persons could obtain telephonic communication for something like £5 or £6 a year, and if this could be done in Cardiff it would be very advantageous to tradesmen and others. The suggestion was agreed to.

Accrington. —The town clerk has reminded the Legal and Parliamentary Committee that he had received the Local Government Board's sanction for the borrowing of the money for the purchase of the land for the baths and electric light station, and he has been instructed to prepare the necessary documents of transfer, and arrange for the completion of purchase immediately after the 12th November next. On the minutes being proposed for confirmation at a meeting of the Town Council last week, Mr. Sprake said he thought the Council was not quite aware of the importance of the matter. So far as he could see they were taking over the land on which the baths were built, and this, he thought, was a matter that was worth a little more consideration. When the site for the electric light station was selected there were several sites submitted for the consideration of the persons who came to inspect the district and this was chosen as the best. Since then, however, the Corporation had entered into arrangements with the gas and water company, and he believed it was intended to practically do away with the present gasworks in Hyndburn road, and use more of the works at Great Harwood. If that was so, the Corporation might be able to arrange matters in such a way that the electric lighting station might be fixed somewhere down Hyndburn road. The electric light was not an absolute necessity at present. There had been no outside pressure brought to bear upon the Corporation, and in the face of the large undertaking the Corporation had entered into with regard to the gas and water works, he thought they ought to proceed slowly in this matter, and not incur further enormous responsibilities. They were rapidly increasing the rates, and were face to face with an expenditure of some thousands of pounds in connection with the

sewage of the district—a burden that would fall upon the ratepayers. In the face of this, he did not think the Corporation were doing wisely in undertaking the responsibility of carrying out the electric light, and particularly baths at this stage. There was no pressing necessity for the Corporation entering into these undertakings, and he moved that the matter be referred to the General Purposes Committee—not with the idea of defeating the ultimate object the committee had in view, but in order that the subject might be more fully considered, seeing the great amount of money there was at stake. Mr Dewhurst seconded Mr Sprake's amendment. Mr. Riley quite differed from Mr. Sprake respecting the electric light. He thought the supply of electricity for lighting purposes was just as requisite as the supply of gas. If he was not mistaken the baths were self supporting, so that there would be no loss in connection with that undertaking. The Council might have noticed that rapid strides were being made in Manchester with regard to the electric light, and that ought to satisfy them as to the wisdom of adopting the light. He thought they had gone too far now to stop in the matter. Mr. Sprake said no outside pressure was being brought to bear, but he said there was. Several persons had asked him what had become of the electric light scheme, and the answer he had given was that the matter had been allowed to lie in abeyance owing to the work the Council had on hand with reference to the gas undertaking. He thought that now the electric light ought to go on just as well as the gas question. After further discussion, the amendment was rejected, and the minutes were confirmed.

Yeadon.—A public meeting of ratepayers has this week been held for the purpose of considering the advisability or otherwise of adopting a system of electric lighting. The chairman of the Local Board (Mr. James Flaxington), who presided, said that the Yeadon Gas Company had given them fair satisfaction both as to price and quality of gas supplied. The electric light, however, was making such progress that the Local Board had come to the conclusion, after thoroughly investigating the matter, that it would be to the interest of the ratepayers to adopt that system of lighting for Yeadon. They had therefore called the ratepayers together to consider the matter. Messrs Andrews and Preece, of Bradford, had submitted a scheme to the Board, and guaranteed that they could furnish electric light—allowing for cost of labour, fuel, interest on capital, etc.—at 4d. per unit, which was equal to gas at a cost of 1s. 6d. or 1s. 7d. per thousand cubic feet, whereas they were really paying at Yeadon 2s. 11d. per 1,000ft. net. The electric light was, therefore, much cheaper than gas, and it was, in addition, a better illuminant. It was proposed to charge 10s. per lamp per annum for the electric light, and there would be no restriction as to the length of time the light was used. Mr Preece, in explaining the scheme proposed by his firm for adoption, said that they were enabled to supply the electric light at the price named by the chairman through the fact that they used Dowson's gas system and gas engines, which reduced the cost of fuel to one third the cost where steam engines were used. At Morecambe, where their system had been in operation some time, the company had—with a charge of 10s. per lamp per annum—been able to pay a dividend of 5 per cent. on the first year's working. In answer to questions, Mr. Preece explained that the kind of gas they manufactured in connection with the generation of electricity was totally different from coal gas. They had to make 4,000 cubic feet for 1,000 cubic feet of ordinary town's gas, but it cost them only 2d. per 1,000. After the 10th of November next the cost of incandescent lamps would be reduced from 3s. 9d. to 1s. Notwithstanding the higher price for the lamps, they had been able to give every satisfaction with the light at Morecambe, and to make the dividend he had stated; while consumers said that their lighting bills were greatly reduced. Mr Thompson Marshall (a member of the Local Board) said that by adopting the electric light they would not only get a better illuminant at a cheap rate, but they would have other advantages in the prevention of dust and danger. The benefit on the score of health would be very great. The members of the Board who had been to Morecambe visited a large number of houses and other buildings indiscriminately, and they were invariably told that the light was good and as cheap, or cheaper, than gas. Mr Bernstein urged that it was an erroneous idea that electricity was simply going to oust gas altogether. It had been found in nearly all places where electric lighting had been adopted that the consumption of gas had increased. Engineers were constantly inventing new appliances in which gas was used, and doubtless that would go on. Mr H. Marshall and Mr. E. M. Chippendale, members of the Local Board, both spoke in favour of the scheme, the latter pointing out that while their 107 lamps cost £1. 14s. 1½d. per annum each in wages and gas, the same number of electric lamps at 10s. each would mean a saving of about £130 a year. It was also pointed out that this and any other monetary advantage accruing from the adoption of the electric light would go to the reduction of the rates. Eventually a resolution was adopted to the effect that the ratepayers were satisfied with the scheme, and that the Local Board should take proper measures for obtaining full lighting powers.

The Reduction in the Price of Lamps.—In the course of an article on the impending expiration of the incandescent lamp patents, the *Financial News* says: "To come down to a practical illustration of the effect of the fall in price, it may roughly—very roughly—be reckoned that it would cost about £70 to wire a house of average size for, say, 50 electric lamps and to supply the necessary plain fittings. The 50 lights would, under the old price, add £9. 7s. 6d. to the price, making it amount to £79. 7s. 6d. With Ediswan lamps at 1s. 6d. each—as already stated, they have not yet reached this figure—the cost would be £73. 15s., showing a reduction of £5. 12s. 6d. This is satisfactory; but the saving is to be seen more clearly in the cost of renewals. The fittings and wiring last, of course, for years, and do not require to be replaced until they show signs of wear; but the incandescent lamps must be renewed at intervals. Each lamp is calculated to burn for about 1,000 hours, its life being measured by the ability of the carbon filament to keep itself together. Allowing that each lamp is alight for three hours each day, its period of existence is one year, and there must consequently be an annual renewal. If they are run properly, the lamps might last for three or four years, while if they are not treated well the filaments might give out in six months; but 12 months is the average life. The cost of renewal, therefore, will be reduced from £9. 7s. 6d. a year to £3. 15s. a year, so that there is considerable economy as regards this item. Unfortunately, the use of the electric light is restricted to some extent by the fact that householders on short leases are disinclined to face the heavy initial outlay on installation. Where the tenant is also landlord the matter is different, but the tenant on a short lease declines to spend a heavy sum on a house which he may have to vacate in a few years, while his landlord usually refuses to bear the major part of the cost. But notwithstanding such drawbacks as these, the electric light—which must for some time to come be called the rich man's illuminant—is bound to become more popular, and the freer use of it will, of course, enable the various supply companies to furnish the necessary current at a reduced rate. Comparisons of the cost of the electric light and of gas, highly favourable to the former, are often made, but in the case of such experiments there is, no doubt, an exceptionally cheap supply of power. It may be taken as a fair basis, and one on which reliance can be placed, that where the charge of the company supplying the current is 8d. per Board of Trade unit—the usual rate—the electric light would cost the same as gas if the latter were supplied at 6s. 9d. per 1,000ft. Hence, if gas is at 2s. 3d. per thousand, the electric light is three times as expensive, and it is twice as costly where gas is at 3s. 4½d. per thousand. It has been pointed out that, in view of the advent of cheaper lamps, consumers may prefer to select lamps of less candle-power than they require and to increase their efficiency by 50 per cent.—*i.e.*, run a lamp of 8 c.p. at 12 c.p. In this way the life of the lamp would be shortened by about one half, and the cost of renewal might be doubled; but the lamps would be cheap, and there would be a considerable saving in regard to the amount of current used. Of course, the lapse of the incandescent lamp patent must affect the position of the Edison and Swan United Electric Light Company; but it will, nevertheless, continue to do a fairly profitable business. As Mr. James Staats Forbes said at the meeting two months ago, the Edison and Swan Company can make lamps as cheaply as an English firm, and probably as any foreign manufacturers. This is due to a large extent to the fact that the company keeps its process of manufacture as secret as possible, and this remark applies especially to the composition of the carbon filament and to the method of exhausting the glass bulb of air. Besides this, it holds many valuable patents as regards electrical fittings, and it has sole rights as regards a lampholder retailed at 1s. 8d., which is almost universally used. As the company does not permit the manufacture of these holders by others except at a heavy royalty, it follows that a consumer of the electric light must either purchase Ediswan lamps or must go without the advantages attaching to this holder. This fact gives the Edison and Swan Company a long pull over its competitors, and will ensure a demand for its products until the holder patent expires. Years ago the company acquired the British rights of the Swan United Electric Light Company, and negotiations are proceeding with a view to the taking over of the remnant of the business—all, of course, foreign—of the latter concern. There may yet be further patents granted in respect of a lamp on the principle of the Ediswan. It is confidently predicted that before very long a lamp will be invented having its filament so constructed that it will give a good light with a consumption of two-thirds of the amount of current at present used. It is mainly the filament which must be improved; for the vacuum will apparently continue to be used in any case, and lamps possessing no vacuum, with a platinum or other filament, have all been comparative failures. When lamps consuming only two-thirds of the present necessary quantity of current are invented the cost of domestic electric lighting will be reduced by one third, and another great development in the industry will be brought about."

Lighting at Taunton.—As mentioned in our last issue, a meeting of the Town Council was held on the 2nd inst., when the Electric Light Committee presented the following report: "Your committee report that they have reconsidered the subject of supplying electricity to Salisbury House, Billet street, and, as the matter was pressing, they have arranged, with the consent of Alderman Van Trump and Councillor Stevens, to extend the overhead wire through these gentlemen's premises, and to carry it underground across Billet street, at a cost not exceeding £20. They have also received an application from Mr. A. Steevens to supply Osborne House with electricity, which they have agreed to do, subject to Dr. Fleming's advice as to the best mode of carrying out the extension. Your committee recommend that as the present charges for arc lamps are remunerative they shall remain as at present, subject to three months' notice of alteration on either side. Your committee have instructed the town clerk to see that the agreement with Messrs. Laing, Wharton, and Down is cancelled. Your committee have had an interview with Dr. Fleming, who will report fully on various subjects when he has considered the information which he has obtained from the officials. The committee ask for leave to carry out any pressing works at a cost not

exceeding £50. Your committee present the contract with the electric light company for the purchase of their works, and they recommend that it shall be sealed with the common seal of the borough." Councillor Potter, the chairman of the committee, moved the adoption of the report. He reminded the Council that at the last meeting the proposal to lay on the light to Salisbury House was referred back to the committee. The committee met the next morning as the case was urgent, and as a result of their deliberations they decided to carry out the work at a cost not exceeding £20. Arrangements were made with Mr. Van Trump and Mr. A. Steevens to run the wire along their garden walls and take the cable across the top of Billet street. This had been done. At the last meeting it was estimated that 15 or 16 lights would be required at Salisbury House; the actual number installed was 20, and thus the revenue would be greater than was anticipated. An application had also been received from Mr. A. Steevens to supply Osborne House with the electric light. In their interview with Dr. Fleming, he suggested various things to the committee, but they had received no definite instruction, because he desired to consider the whole question—the economical working of the light, the suggested extensions, etc. For that purpose he requested that a map of the borough should be sent him, with other information which he sought from the borough surveyor. All that had been done and he was now considering the whole position, and would give them a report advising them as to what would be the best things to do. The committee had agreed to make the extension to Osborne House, subject to the approval of Dr. Fleming. The number of lights required would be about 50. As the Council would be compelled to put the wires underground within two years, it was thought best to put the cable at once underground along Upper High street. The wire for incandescent lighting extended no further than Dr. Iles's house, and the proposal was to extend the incandescent wire from that point to Osborne House and put the whole underground. The incandescent cable could then be used for street lighting. There were three gas lamps in the street, and an incandescent lamp could be placed on one of them. That would tend to increase the income. The committee recommended that the present charges for arc lamps should not be changed, for one or two reasons. It was thought that some of the arc lamps would be thrown out in favour of incandescent lights, and it was not desirable to fix meters for arc lamps. And as it was carried on at a price which entailed no loss to the Council, it was thought desirable not to interfere with the arcs at present. That arrangement would be subject to three months' notice on either side. In compliance with the wish of the Council, the committee had instructed the town clerk to see that all agreements with Messrs. Laing, Wharton, and Down were cancelled, and he believed that had been done. The committee asked for permission to carry out any work not exceeding £50 in cost. The committee did not ask the Council to empower them to spend money to the extent of £50 without bringing it before the Council if they had an opportunity of doing so, but only in the case of urgency, such, for instance as that of Salisbury House, when it would not be convenient to defer the carrying out of the work until the meeting of the Council. If the works were to be carried to a successful issue the Council must give some power to the committee in this respect. The committee presented the contract for the purchase of the works, which had been drawn up by the town clerk, on behalf of the Council, and Mr. Kite on behalf of the company. The contract had been submitted to counsel, and in its present form had received counsel's approval. Councillor Hammett seconded the adoption of the report, which, with the exception of the recommendation as to Osborne House, was adopted. At a monthly meeting of the Town Council on Monday a long discussion took place on a charge of the town clerk's amounting to £135, made in respect of legal work done by him in connection with obtaining the electric light license and provisional order. The Town Clerk (Mr. T. Meyler) stated that all the charges were strictly accurate, and he could substantiate them before any taxing master. The account was passed. The Electric Light Committee were empowered to procure a new boiler for the works.

PROVISIONAL PATENTS, 1893.

OCTOBER 2.

18386. **Improvements in electrical switches.** Edward William Lancaster, Albert Works, Graham-street, Birmingham. (Complete specification.)

18392. **Improvements in electric clocks and watches.** William Walter Gerald Webb, 9, Coppenhall-terrace, Crewe.

18403. **Improved means of intercommunication by telephone.** John James Mann, 4, St. Ann's square, Manchester.

18404. **Improved means of intercommunication by telephone.** John James Mann, 4, St. Ann's square, Manchester.

18428. **Improvements in electric telegraphs and mechanism used in connection therewith.** George Draper and Angus Fraser, 24, Southampton-buildings, Chancery-lane, London.

OCTOBER 3.

18457. **Electrically-lighted letters.** Henry Hawksey, 6, St. John-street, Deansgate, Manchester.

18460. **Improvements in armatures for dynamo-electric machines and electric motors.** Martin Rahner, 34, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18475. **Electric signals for railways.** Arthur Moore Thompson, Crewe Works, Crewe.

18482. **Means for determining the presence and intensity of atmospheric electricity.** Jesse Opperman, 55, Chancery-lane, London. (Complete specification.)

18524. **Improvements in indicators chiefly designed for use at telephone stations also used for advertising purposes.** Ignatius Raleigh Burns and Walter Francis Burns, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

18530. **Improvements in the arrangements and connection of conductors for electric railways.** Siemens Bros. and Co., Limited, and George Herbert Thornton, 28, Southampton buildings, Chancery-lane, London.

OCTOBER 4.

18586. **An improved regulator for arc lamps.** Leon Zausmer, 6, Lord street, Liverpool.

18596. **Improvements in the means or mode of protecting insulators as employed for electrical purposes or appliances.** William Martin, Victoria-chambers, Martineau street, Birmingham.

18602. **Improvements in telephone switchboards.** Charles Denton Abel, 28, Southampton-buildings, Chancery lane, London. (Société Générale des Téléphones, Reseaux Telephoniques et Constructions Electriques, France.)

18609. **Improved telephone attachment.** James Gilbert Foster, 55, Chancery lane, London.

18610. **Improved electrical heating apparatus.** Percy Richard Julius Willis, 55, Chancery lane, London. (Charles E. Roehl, Sidney Z. Mitchell, and Earl P. Whetmore United States.)

OCTOBER 5.

18626. **Improvements in electrical conductors.** John Baragwanath King and Thomas Edwin Bickle, Great Western Docks, Plymouth.

18661. **Improvements in electric telegraphs for steering, engine-room, and other signalling purposes.** Frederick George Panizzi Preston, 77, Chancery lane, London.

18674. **Improvements in electrical receiving instruments and relays.** The Phonopore Company, Limited, and Charles Ernest Spagnoletti, 28, Southampton buildings, Chancery-lane, London.

18690. **Improvements in conduits for electric conductors.** Charles Gordon Picking, 47, Lincoln's-inn-fields, London.

OCTOBER 6.

18734. **Improvements in electric meters.** Hans Peter Olsen, 46, Lincoln's inn-fields, London.

OCTOBER 7.

18805. **Improvements in electric measuring instruments.** Benjamin Davies, 6, Lord street, Liverpool.

18841. **An improvement in incandescent electric lamps and sockets.** The Edison and Swan United Electric Light Company, Limited, and John Ambrose Fleming, 28, Southampton buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1892.

14124. **Electromotors.** Hurd. (Second edition.)

16335. **Electric telephonic apparatus.** Harrison.

16615. **Electric incandescent lamps.** Froggatt.

17653. **Electric batteries.** Lohman.

20415. **Microphones.** Gent and others.

21782. **Electrical resistance coils.** Siemens Bros. and Co., Limited, and Nobel.

1893.

5094. **Electrolytic decomposition of solutions of chloride of sodium, etc.** Richardson.

13888. **Electric current, etc., governors.** Wiese.

NOTES.

The Madras Tramway.—Work in connection with the erection of the generating station has been commenced.

Cork.—A large arc lamp has been placed outside the Munster arcade, Patrick-street. It is the only public arc lamp in the town.

The "Revenge."—This battleship is lighted by 700 electric incandescent lamps, and there are also four very powerful search-lights.

Piezo Electric Pile.—The paper read last week by Lord Kelvin before the French Academy of Science dealt with a piezo electric pile.

Vienna.—The Berlin Electrical Company is reported to have obtained the concession for all the electric tramcar lines to be constructed in Vienna.

Taunton.—A correspondent suggests the utilisation for the production of the electric light of the water power at the weirs at each end of the town.

Madrid.—A system of electric tramways is to be introduced in Madrid, a German electrical company being largely interested in the enterprise.

The Seine.—The Service de Sauvetage of the Seine has in use a system of electrical communication between the salvage points and the central office.

Milan.—An electric tramway on the Thomson-Houston system, between the Piazza del Duomo to Porta Sempione, will be set in operation in a few weeks.

Police Lamps.—Experiments are being made with hand electric lamps for the Dundee police force, and it is possible that some such type of lamp will be adopted.

Baltimore.—A fire caused at the Brush electric light station by two wires becoming crossed has resulted in heavy losses to the company and in the burning down of a gaol.

Bradford.—On Monday, Mr. J. W. Riley, D.Sc., delivered before the Bradford Scientific Association an address on "Central-Station Systems of Electric Lighting."

Personal.—We regret to learn that Prof. Helmholtz met with an accident on the voyage from the United States to Bremen, and that it has necessitated his removal to hospital.

An Electric Chronograph.—An electric timing apparatus, invented by Sterling Elliott, has been officially recognised by the Racing Board of the League of American Wheelmen.

Regent-street Polytechnic. — A course of 30 lectures has been commenced at the Polytechnic Institute, Regent-street, W., in electrical engineering and experimental physics.

The Double Event.—See the daily papers of Monday and the *Pall Mall* of Thursday—first and second blows—viz., Harness goes for £55,000 new issue; the *Pall Mall* goes for Harness.

The Institution Annual Dinner.—The annual dinner of the Institution of Electrical Engineers is to take place on Wednesday, the 22nd November, at the Freemasons' Tavern, Great Queen-street, W.C.

Lighting in Berlin.—At present there are in Berlin about 160,000 incandescent lamps of 16 c.p. energised from the network of the Berlin Electricity Works. The company have introduced several systems for automatically indicating faults.

Small Motors.—Electromotors of powers ranging from $\frac{1}{25}$ h.p. to $\frac{1}{8}$ h.p. are being introduced by Messrs. Bauer and Betz, of Berlin. They are on the "Betz" system, and are intended for use in houses and for small industrial operations

Telephony.—Instructions have been given for the immediate laying of cables between the shore and the Kentish Knock and North Goodwin Sands lightships for telephonic communication, so that the work may be done before the winter sets in.

Station-Lighting.—As mentioned in a previous issue, the Great Northern Railway Company have for some time past been engaged on the lighting by electricity of the King's Cross Station. The work is now nearly completed, and in addition to the station, the hotel is being electrically equipped.

Wilhelm Weber.—The Royal Society of Science at Göttingen has published the works of Wilhelm Weber, who was at one time professor at that university. The name of Weber is well known in the world of science. Weber's writings have now been collected into five volumes, edited by the Scientific Society of the university.

Edinburgh.—The deputation of seven members of the Town Council to various cities in England on the subject of electric light, and which was absent for eight days, cost £173. 10s. The Town Council have confirmed the minutes of the special meeting held last week resolving to lease the tramways to Messrs. Dick, Kerr, and Co.

Train-Lighting.—The success attending the working of the electric light on their trains has induced the directors of the London, Brighton, and South Coast Railway to give instructions for 10 additional trains to be equipped with it. When these are running, the company will then have 40 trains to which this mode of lighting has been applied.

Wind Power.—M. de Rufz, of St.-Lunaire, has lighted his residence by electricity, the power being obtained from a windmill of the "Eclipse" type. The windmill is arranged on a masonry tower at a height of 33ft. from the ground, and the power is transmitted by gearing and belt to a dynamo which charges accumulators from which 25 incandescent lamps are energised.

Phonographs and Ear Diseases.—The attention of the authorities has been called to the fact that danger lurks in the phonographs which are in public use in various parts of the town. It is submitted that in America these instruments caused diseases of the ear to largely spread, and that it became necessary to compel each exhibitor to cleanse by acids the tube after individual use.

Traction at Newcastle.—A sub committee of the Tramways Committee of the Corporation has been appointed to meet the members of a syndicate and discuss details as to proposals made for the running of the trams by cable on the different lines in the city, and for the doubling of the whole of the single lines, and to extend the tramway system. Is there any chance for electric traction?

The French Transformer Action.—As a result of the action which they gained over the Compagnie Internationale d'Electricité de Tours, and to which reference was made some weeks ago, Messrs. Zipernowski, Deri, and Blathy have caused to be seized the transformers of the Thomson-Houston and Ferranti type used by the Société l'Energie Electrique at Havre. It is said that a further action on the matter will be entered upon.

Economy in Fuel.—Mr. Riley, in a paper read before the Royal United Service Institution, considers that the principal direction in which to look for economy in the consumption of coal on board ship is in the auxiliary engines, particularly those used for electric lighting purposes.

He mentions that the "Warspite," on passage to her station, charged four tons per day for lighting purposes, which, after arrival, was diminished to three tons and less.

South Staffordshire Tramways.—These tramways continue to attract a good deal of attention. M. Gerrard, Chief Minister for Railways, Telegraphs, and Post Offices for Belgium, has paid an official visit on behalf of the State authorities of his country and made a complete examination of the line and installation. Then the mayor and town clerk of Leeds have made a like visit and inspection, and reported so favourably that the entire Corporation has since made an examination.

Lightning Conductors.—According to a note by M. Precht, the discharge from lightning conductors can only be produced when the potential reaches 15,009 volts. Even very fine points can be charged up to 25,000 volts before giving a continuous discharge. The presence of large quantities of dust or of gas round the points renders the discharge more difficult, whilst the ultra-violet light facilitates it. A group of points can be charged at a higher potential than a single point.

Frankfort-on-the-Maine.—The Town Council has adopted the proposal of the Executive Department for the erection of municipal electric light works, according to the plans submitted by Messrs Miller and Lindley, on the alternate-current system with transformers, and a low-tension distributing network. Messrs. Brown and Boveri, of Baden, Switzerland, have been entrusted with the construction of the alternators, and Messrs. Felten and Guilleaume, of Cologne, with the supply of the cables.

Electrical Laboratory.—An electrical laboratory has been opened in Paris by the Société Internationale des Electriciens, a former president of this society, the president of the Syndicat des Industries Electriques, and a delegate of the municipality. Lectures are to be arranged, and systematic investigations into questions connected with electricity will be made. Apparatus will be tested and experiments made for the public, and under certain conditions persons will be admitted to make tests and conduct investigations on their own account.

Liquid Fuel.—Mr. F. J. Hadfield, in dealing with the coal strike as an economic error of the gravest kind, has no hesitation in saying that steam users are at the present moment wholly independent of coal, and that it only needs a little further pressure to ensure the market being inundated with crude petroleum and aslatki, both of which products can be very successfully used for heating purposes and the manufacture of gas. Having obtained steam alone, electricity, he states, can do all the rest. This he hopes will serve as a warning both to masters and men.

Traction at Leeds.—It is interesting to note that the Highways Committee of the Corporation have decided to renew for six months the lease of the line for the working of the electric cars to Roundhay Park, and after that for an ensuing period of one month at a time until a final decision is arrived at. As mentioned in another column, the Highways Committee have inspected the Walsall electric cars, and a special meeting of the committee will shortly be held to consider the subject of traction on the whole of the Leeds tramways.

The Fatal Accident.—The Board of Trade was represented on Monday at the adjourned enquiry into the circumstances attending the death of F. W. Ball, who was killed at the Blackfriars-road transformer station of the London Electric Supply Corporation on the 12th ult. The facts of the case were given in our issues of the 15th and 22nd ult. Further evidence was given, and the enquiry was again adjourned until the 16th January, to allow of the jurymen to visit the station, and for E. Meach, who was injured at the time of the accident, to be able to attend.

The German Accumulator Action.—Judgment was pronounced on Wednesday against the plaintiffs in the action brought by the London Electric Power and Storage Company against the Pollak Company, the proprietors of the accumulator works in Frankfort-on-the-Maine, to restrain the latter from manufacturing or selling accumulators. This is the first time that a German court of law has given a different decision from that pronounced in similar actions against other accumulator manufacturers preferred by the actual patentee—namely, the Accumulator Manufacturing Company of Hagen.

The Tramways Institute.—A meeting of the General Council of the Tramways Institute of Great Britain and Ireland took place last week at the offices of the Birmingham Central Tramways Company. Mr. W. J. Carruthers Wain presided, and there were also present Messrs. J. Ebbsmith (chairman Birmingham Central Tramways), A. P. Smith (chairman Bury, Rochdale, and Oldham Tramways), R. Whittaker (chairman Southport Tramways), William Mason (director of the Bradford Tramways and Omnibus Company), and J. G. B. Elliott (secretary). Several matters of special interest to tramway companies were discussed.

Chicago Exhibition Awards.—The following awards are announced for the electrical exhibits: British Government Postal Telegraph Department, modern telegraphic apparatus in operation, and historical telegraph apparatus; Corporation of Birmingham, original Woolwich dynamo; General Electric Company, Limited, London, H I switches and other incandescent house fittings; James White, Glasgow, electromagnetic balances (Kelvin). In the transportation section, the London and North-Western Railway Company receive an award for the application of electricity to boiler-shop tools and for electric train staff apparatus.

A New Motor.—On Wednesday, Major-General Hutchinson, R.E., visited Croydon for the purpose of inspecting, on behalf of the Board of Trade, a new tramcar which is about to be used on the Croydon and Thornton Heath section of the Croydon and Norwood Tramways Company. It is known as the Lührig gas car, and is propelled by gas motors. It is said that from experiments made by Prof. A. B. W. Kennedy, F.R.S., it has been found that in ordinary circumstances the cost of traction will be reduced by about 65 per cent. The gas is ignited by an electric spark, and the motors consist of two double-action 7-h.p. gas-engines.

Fog-Signalling by Electricity.—In a recent issue we suggested the introduction by railway companies of a mechanical or electrical system of placing fog-signals on the metals. We are now glad to learn that the Great Northern Railway Company are extending on their North London branch lines the experiment of fog signalling by means of electricity. The method of working is simple, and is the invention of an electrician in the employ of the company. The system, which is in working order at Wood Green, has proved so satisfactory that the company have decided to fit up the suburban lines, and probably make further extensions at no distant date.

Steam to Aid Water Power.—The necessity for making some provision against the contingency of the river level falling considerably where the water power is used to operate turbines for electric lighting, is shown in the case of Toulouse. There the waters of the Garonne have fallen to such a large extent that not only have many industrial establishments in the neighbourhood been obliged to shut down, but the local electricity company, which usually has

four turbines at work, can now only operate one. This has necessitated a curtailment of the electric lighting, and it shows that auxiliary steam plant would have proved of great advantage in the emergency.

The "Volta" Lamp.—This lamp, which is to be introduced by the British Volta Electric Glow Lamp Company, of 49, Queen Victoria-street, E.C., on the expiration of the Edison patent next month, is claimed to have the high practical efficiency of 2·7 watts per candle-power. It is also asserted that with the "Volta" lamp the light does not fall off rapidly, that the bulbs do not become black, and that the current or voltage does not require to be raised to keep the lamps at their original brilliancy. The lamp will be manufactured of 8, 10, 16, and 32 c.p., ranging from 50 to 110 volts, and with, it is said, an efficiency of 2·7, 3, and 3·5 watts per candle-power as may be required.

The Russians at Toulon.—As Admiral Avellan, after quitting the "Formidable," entered the new harbour on his way to the arsenal, all the search-lights of the fleet were concentrated upon his boat. At the arsenal, in an enormous ballroom, a grand ball was given to the Russians by the officers of the French Army and Navy. Beneath the inclined, barn like roof was a temporary ceiling of bunting, and depending from it were six gigantic chandeliers formed of pistols and revolvers and bearing incandescent lights. A central chandelier, larger than the rest, was formed of 70 pistols, 30 sabres, and 25 pistol barrels, the last being mounted as candles, and each bearing an Edison lamp. There were also many arc lamps.

Electricity in Mining Operations.—In the course of his inaugural address on Saturday to the North of England Institute of Mining and Mechanical Engineers, Mr. A. L. Stevenson said that he doubted very much whether, for lighting purposes, electricity would be of much use to the mining engineer. No great light was required at the surface, but if the fire risks could be overcome, it might be of value in the cleaning and screening of coal. He said that many attempts had been made to produce portable miners' lamps, but, for his own part, he was so thoroughly satisfied with the safety of the lamps now in use, that he had not taken much interest in the attempts to solve the electrical difficulty. For the transmission of power beyond a thousand yards, electricity had proved its value, and the cost would, he hoped, be capable of reduction. Whether it was a suitable medium to be taken beyond the lamp station or the caution-board, those who adopted it, he remarked, must decide for themselves.

Stopping Generating Plant.—A method for stopping generating plant at a distance without the use of an extra wire has been devised by Mr. R. H. Postlethwaite, A.I.E.E., of Dunedin, New Zealand. The device consists of an electromagnet wound to carry the total current. When the plant is started a weight is attached to the poles, the weight being in communication with the turbine or water-wheel regulator either by a system of weights or cords and pulleys. As soon as the main switch is opened the magnet loses its power, the weight drops, and the gates are hereby closed. The magnet is designed so as not to let go until all the current is cut off. The last installation carried out with the use of this device was for a private residence, the turbine being about half a mile distant from the house. The weight when dropping first throws a governor out of gear and then shuts the turbine gates. The main switch is arranged in the owner's bedroom, so that he can shut down after retiring to rest.

Lighthouse Communication.—The Lord Mayor on Wednesday evening entertained at the Mansion House the Elder Brethren of the Trinity House and the Conservators of the Rivers Thames and Lea. Sir Sidney Webb, in the course of his reply to the toast of "The Trinity House," said that effect had already been given to some of the recommendations of the recent Electrical Communication Commission. Several outlying lighthouses on the mainland were now in direct connection by telephone with the postal telegraph system of the country. Telegraph cables had also been laid to Lundy Island and the Gunfleet Lighthouse. The Kentish Knock light vessel, 18 miles from land, and the Goodwin, five miles out, both important as look-out stations, the one for the Thames entrance, and the other for the trade route through the Straits of Dover, were about to be connected in like manner with the shore. For this particular work a special grant had been voted by Parliament, and the operations were being carried on in conjunction with the General Post Office.

Measuring the Efficiency of Dynamos.—In a note addressed to the Association des Ingenieurs-Electriciens sortis de l'Institut Montefiore, M. Felix Mélotte refers to the most generally used methods to determine the efficiency of electrical plant, and to the method which he employs to avoid heating of the band brake. At the Ecole des Mines in Belgium use is made of hollow pulleys, which receive a current of cold water, which afterwards passes freely away. This system is not directly applicable to the pulleys of electric motors, which on account of their great circumferential speed might have thrown the water violently on all sides. To avoid this, M. Mélotte inserts a bent tube in the opposite direction to that in which the motor is revolving, and in the interior of the pulley. The water introduced in the pulley is held on the felly by the effect of the centrifugal force, and takes part in its motion. When there is a certain quantity of it, its surface touches the tube, enters it, and passes out without a drop being lost. In this manner it has been possible to test a motor of 6 h.p. at a speed of 1,200 revolutions with a pulley 15cm. in diameter, and keep the speed for more than 10 minutes.

Electro-Harmonic Society.—The second smoking concert of the season will take place on Friday evening next, the 27th inst., at the St. James's Hall Restaurant, Regent-street, W., commencing at eight o'clock. The following is the programme: Part I: Madrigal, "What ho!" (Beale), Messrs. Lester, James, Kearton, and Miles; song, "I will Come" (F. H. Cowen), Mr. Albert James; pianoforte solo, "Rhapsodie" (No. 13) (F. Liszt), Mr. Alfred E. Izard; song, "When Bright Eyes Glance" (Hedgecock), Mr. R. E. Miles; violin solo, "Fantaisie—Scène de Ballet" (De Bèriot), Mr. T. E Gatehouse; recitation, Mr. Fred. Frampton; song, "The Sailor's Grave" (Sullivan), Mr. Harper Kearton; humorous sketch, Mr. James Kift. Part II.: Duet, violin and pianoforte, "Andante Rondo" (Kücken), Messrs. T. E. Gatehouse and A. E. Izard; old ballad, "I Lov'd the Maid for Loving Me" (G. W. Maddison), Mr. Albert James; song, "King and Slave" (F. Allitsen), Mr. R. E. Miles; violin solo (*a*) "L'Addio" (Schubert; transcribed by T. E. Gatehouse), (*b*) "Canzonetta," from "Concerto Romantique" (B. Godard), Mr. T. E. Gatehouse; Irish song, "Paddy O'Rafther" (Lover), Mr. H. Lester; recitation, Mr. Fred. Frampton; old ballad, "Tom Bowling" (Dibdin), Mr. Harper Kearton; humorous sketch, Mr. James Kift.

Massage and Galvanic Conduction.—In the course of a paper dealing with massage in diseases of the skin, Dr. A. Symons Eccles says: "Perhaps one of the most interesting effects of massage to dermatologists will be the influence which it has been repeatedly observed to exercise on galvanic conduction. This I have already noted in more than one of my previous papers; but in view of the possible value which may arise from the employment of the cataphoric action of the constant current in the treatment of skin diseases, it may not be out of place to refer

again briefly to the indisputable fact that massage greatly decreases the resistance of the uninjured skin to the passage of electrical currents. I have repeatedly observed that previous massage of a part will economise the number of cells necessary in order to pass a given number of milliamperes of current through the skin, and that whilst the same current may be maintained during the application the number of cells in action may be more rapidly reduced than is possible when massage has not previously been employed. I venture to suggest that if it is desired to use the alternating constant current for the purpose of percutaneous medication by saturating the electrodes with a watery solution of the substance selected for use, the preliminary application of massage may most probably be found to increase the rapidity with which the drug will be absorbed, just as it undoubtedly reduces the resistance of the tissues to the passage of the electric currents."

Electric Water-Level Indicator.—In the *Proceedings* of the Institution of Civil Engineers there is described an apparatus, designed by Mr Dieudonné, to indicate the water-level in a reservoir, boiler, etc., at any distance by means of electric signals conveyed by a telegraph wire. The float is connected by a cord to the edge of a circular sector free to turn on its centre, and the pull of the cord is counteracted by that of a dead weight, so that the angular motion of the sector always corresponds to the rise or fall of the float. The sector is of metal, and passes over in its rotation a number of metallic radial arms equally spaced. The electric current reaches these arms through the sector, so that in various positions of the sector different numbers of the arms are in the circuit. Another part of the transmitting apparatus is a semi-circle of ebonite, on which are a number of metal plates, each of which is separately connected by wire with one of the arms above spoken of. On this ebonite plate is a radial arm, which, when it revolves, successively touches each of the metal plates. At the receiving station, when it is desired to know the water-level, all that is necessary is to complete the circuit by pressing a button. Suitable electromagnetic apparatus then causes the radial arm to travel over the ebonite plate, and in doing so the circuit is made and broken for a number of times, which indicates the position of the sector and so of the float. A telephone is used to count the number of breaks in the circuit, and any degree of precision may be obtained by choosing the number of radial arms to correspond with any desired scale.

A T-Square Attachment.—The attachment consists of a bar provided with two slotted metal struts, secured to it by screws. This bar is placed against the working edge of the head or stock, and under the blade of any ordinary T-square, so that the struts lie on the upper surface of the head. By means of milled screws passing through the slots of the struts into plug nuts fixed in the head of the T-square, the bar may be securely locked at any desired angle to the blade of the T-square. It will be evident that if the T-square be now put in position on a drawing-board with the edge of the bar doing duty for the working edge of the head, the blade will have an inclination corresponding to the angle at which the bar is fixed. By means of this attachment any ordinary T-square may be converted so as to embody all the advantages of one having a movable head, and at the same time it will be found to be more rigid and less liable to get out of position. The attachment may be removed by taking out the two milled screws, when the T-square resumes its ordinary appearance. Should it be desired to make any additions to a drawing, or to make a tracing from a drawing, such drawing may be *pinned* down on the drawing board without reference to the T square; or it may be that a drawing is already attached to a board, and the T-square applied to it may not coincide with the horizontal lines—in either of these cases, by the adoption of the attachment, a correct adjustment may be immediately obtained. Unless there is much use in an office for such an appliance as is described, one attachment may be made to do duty for several T-squares, provided each is fitted with plug nuts. This attachment has been devised by Mr. James P. Maginnis, of 9, Carteret-street, Westminster, S.W.

G.W.R. Mechanics' Institution, New Swindon.—A special meeting of the Junior Engineering Society in connection with the recent excursion to London on September 16 was held in the lecture hall of the institution on Friday last. Mr. A. E. Leader presided over a moderate attendance. Mr. H. G. Cotsworth read a very good paper on the City and South London Electric Railway, the first place visited by the members on the above date; and of the other—viz., the G.W.R. Electric Lighting Works at Paddington—the manager, Mr. G. B. Clifton, responding to the invitation of the meeting, gave an interesting description later on in the evening. Mr. Cotsworth's paper opened with an account of the restrictions and obstacles the engineers had to contend with in the construction of the railway, diagrams showing the Greathead system of tunnelling were submitted, with a description of the operations, supplemented by the details of the design of the tunnel and an enumeration of its most interesting features The working of the system, safety appliances, and brakes employed, and the hydraulic lifts all came in for attention, and the paper concluded with full details, illustrated by sketches of the electric locomotives. Mr. Clifton, assisted by sketches, very clearly defined the arrangement of the plant at Paddington, and commented on the reasons for and advantages of the system. Full and instructive particulars of the construction of the dynamos were advanced, and also of the running and general output of the machinery. The chairman, with Messrs. Clifton, Cotsworth, Tincknell, T. C. Davidson, Seymour, and Shepherd, joined in the discussion, in which views were freely exchanged on the haulage, general working, and locomotives on the electric railway, and also on the two systems of electric current transmission and the construction and lubrication of dynamos.

French Cable in the Pacific.—"The laying of the French cable between Queensland and New Caledonia is of itself evidence of enterprise which at a dull time is satisfactory. Indeed, we might well add," says the *Melbourne Argus*, "that Victoria would have gladly borne a share of any subsidy required to establish communication with the French settlement (supposing there were no ulterior object) on the well-understood principle that what is to the advantage of one colony is to the advantage of all. But in regard to this particular cable there are well-known circumstances that give an unpleasant tone to the announcement that it is to be laid in a few days. It is intended to be a link in a great Pacific cable to connect Australia with America, and if its projectors succeed in their scheme it will be almost wholly under French influence. Though primarily the contract with Queensland and New South Wales is for a cable to New Caledonia, the avowed object (and to this the two colonies have virtually committed Australasia) is to extend it to Canada. In other words, what is tantamount to an Australasian bargain has been made by two members of the group without consultation with the others, and the Governments of Victoria, South Australia, Tasmania, and New Zealand have been powerless to interfere. It has not, of course, been absolutely decided to continue the cable from Noumea to

Vancouver; but once the first section is laid the French company will command the situation. There is not likely to be room for two Pacific cables for a generation or more, and if the French line is laid, as appears probable, it will have a monopoly of business. In view of the desirableness, from the national standpoint, of having the connection between Australia and Canada wholly under British influence, the prospect is certainly displeasing. It is the more so because of the feeling that Queensland and New South Wales have to some extent jockeyed the other colonies, Queensland having a special object in doing so, because her governments have been consistently unfriendly to the existing cable service. They have assumed a federal responsibility without federal sanction, and their action is calculated to greatly strengthen French interests in the Pacific. If ever need were shown for the federation of the colonies, this is an instance. As it is, the only course open for the dissenting colonies is to notify that they are not bound by any promises made by the Queensland and New South Wales Governments to support the extension of the cable beyond New Caledonia. Knowledge of their dissent may have a restraining effect upon the projectors of the line." The *St. James's Gazette* in a recent issue reprinted the above Australian opinion on the Pacific cable. Since then the cable has been laid.

Apparatus for Measuring Insulation. — In the foreign abstracts of the Institution of Civil Engineers, an apparatus for measuring insulation is described as given by M. H. Armagnat in *L'Industrie Electrique*. In 1881 Mr. Carpentier devised an instrument consisting of two concentric coils fixed with their planes at right angles to one another, and embracing a movable system of magnets or soft iron. The coils were connected in parallel, and on passing current through them the resultant field caused the movable system to take up a position proportional to the ratio of the currents in the coils, and therefore of their resistance. The idea was not novel, having been published by Maxwell, and Mr. Carpentier abandoned it. With the development of electric lighting, a demand has arisen for an instrument that will bear rough usage and indicate resistances in a simple manner with a fair amount of accuracy. The instrument just described is very suitable and has been revived by the inventor. In its original form it was very liable to be affected by the earth's field, and in order to render this negligible the field due to the coils must be very strong. In the improved instrument there is combined the principle of the Deprez-d'Arsonval galvanometer; instead of fixed concentric coils, two rectangular frames are mounted at right angles to one another, and are carried on pivots working in jewelled holes; they move in a very intense field set up by horseshoe magnets, the circuit of which is completed by pole-pieces of fixed soft-iron cylinders. The current is led into the coils by long spirals of very thin silver wire, the disturbing effect of which on the deflection is negligible at a pressure 20 per cent. less than that employed. One coil is connected to the source of current and the other in series with the resistance to be measured, the circuit so formed being placed as a shunt to the first coil. The resultant field is a minimum when one coil acts alone—*i.e.*, when the resistance to be measured is infinite—and a maximum when the maximum current flows through both—that is, when the resistance is zero. The disturbing effect of the leading-in wires is, of course, of greatest relative importance when the field is at a minimum, and it is arranged, therefore, that they shall tend to direct the index towards infinity. A switch is provided which alters the sensibility by shunting the coils, the instrument reading up to 50,000 ohms, 500,000 ohms, or five megohms, according to the position of the switch. A magneto-electric generator, giving 120 volts at 100 revolutions of the handle per minute, is provided. The author points out the necessity for the current being continuous, in order to avoid error when measuring the insulation of cables having appreciable capacity. When the speed is such that 100 volts is attained, variations in speed do not affect the indications of the instrument.

The Hydrograph.—The remarkable property possessed by water for conducting sound is well known, but we are not aware that any successful attempt has hitherto been made to turn that property to account for signalling purposes. Its utilisation in that direction, however, seems to have been effected in a practical manner by Captain Neale, who has devised a system by means of which signals can be given, messages exchanged, and conversation held between ships on the sea or on rivers, whether moving or stationary, or between ships or lighthouses and harbours, forts, or piers on the shore, or *vice versâ*. Communication, moreover, is effected without any connection whatever between the two objects except the body of water in which the ships float or the lighthouse stands, the water being the sole medium through which the message is transmitted. The system depends for its action upon harmonics, and its principle will be understood by a reference to the well-known fact that upon a musical note in a given key being sounded an object capable of emitting sound in the same key will, under certain conditions, sympathetically respond by emitting a sound similar to that which awakened its vibrations. It is, of course, a primary condition that the two objects shall be normally tuned in unison. Working upon this fixed principle, and utilising the high conductivity of water for the transmission of sound, Captain Neale has constructed a signalling apparatus, which consists of a transmitting and receiving instrument, which, when in operation, are in no way connected with each other except through the medium of water. The apparatus by which a correspondent of the *Times* recently saw the system exemplified is mounted on two punts, the transmitter on one and the receiver on the other. The transmitter consists of a bell about 16in. diameter attached to the lower end of a framing which is fixed to the side of the punt, the bell being submerged about 6ft. At the upper end of the framing is a crank handle, which is worked from the punt and actuates a double-beat hammer which strikes and sounds the bell. The Morse code is employed, and signalling is at present carried on by hand, but electricity is intended to be used. The operator gives the handle a quarter turn for the dots of the code, and a whole revolution for the dashes. The receiver, which is on the second punt, consists of a pair of metallic drums, about 10in. diameter, open at one end and fixed, mouth to mouth, upon a piece of board which is sandwiched in between them. These drums are suspended in the water, and are connected up with a small battery, and through it with a tape recording instrument. As at present arranged, the operator has an acoustic apparatus connected with the drums, by means of which he hears the sounds from the bell as they are received by the drums, and, by a manual arrangement, he records each sound on the tape. Upon the occasion of the inspection, the two punts were moored in the Thames at Kingston, about two-thirds of a mile apart, and signalling was successfully carried on from the one to the other. Messages were correctly transmitted and recorded, although naturally somewhat slowly, owing to the apparatus being at present worked by hand. The trial, however, is said to have demonstrated the practical character of the invention and the correctness of the principles upon which it is based.

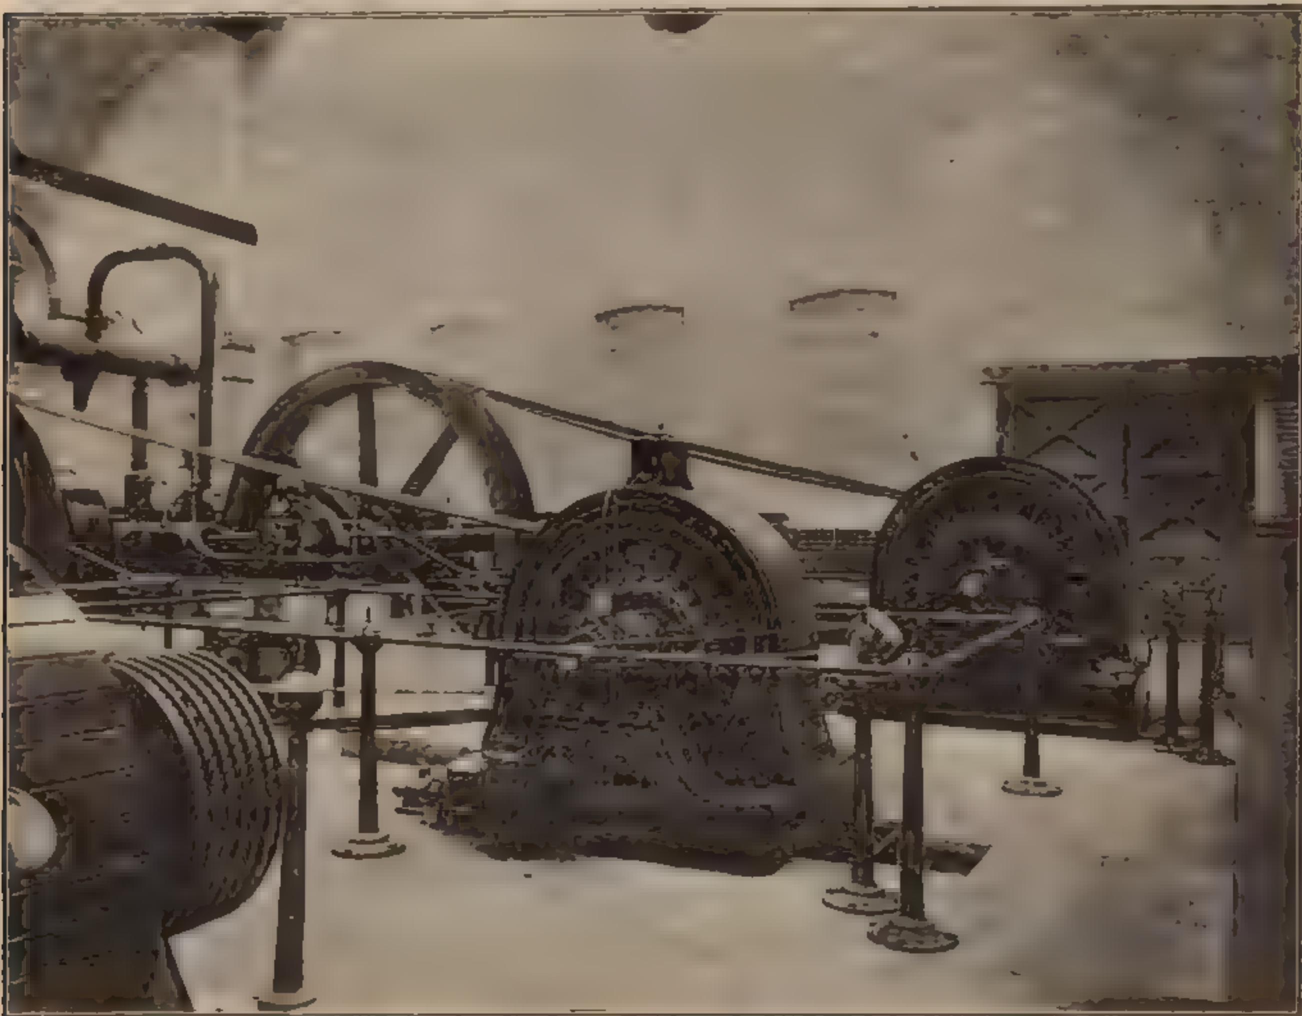
BLACKPOOL.

Last week was a busy week in matters electrical, seeing that two central stations controlled by municipalities were formally opened. The Derby station we referred to in our last issue, the opening of that station being on the Tuesday, while the opening of the Blackpool station, to which we shall now refer at some length, was held on Friday. Blackpool, as many of our readers well know, prides itself upon being the Brighton of the North-West. Its desire is to attract visitors, and no stone is left unturned to accomplish this object. A magnificent sea front, with its three piers, its sands, and miles of promenade, are the main features of attraction, but other places have as good sand and sea, which fail to render them as popular as Blackpool. A popular seaside town must have other than natural attractions, and Blackpool recognises this; hence its piers with their pavilions, its winter gardens, its Eiffel tower, not to speak of theatres and other places of amusement. Private enterprise may do much in providing attractions, as it may in establishing good hotels and boarding-houses, but the authorities are interested in obtaining the best sanitary arrangements, the best water, the best roads and streets, and the best light. Blackpool may fairly feel satisfied with itself in these directions. Our interest is more in matters relating to traction and lighting, in both of which Blackpool is progressive than in the other matters mentioned. In 1878 some little excitement was given to electrical circles by the success of the Jablochkoff candle, and it was not long after this that Blackpool thought the lighting of the promenade by electricity might prove an attraction. The late Sir W. Siemens—or perhaps we ought to say the firm of Siemens Bros.—undertook the work, and erected some half-dozen arc lamps of 6,000 c.p. nominal upon masts 60ft. high along the parade. Each lamp was energised by a separate machine, and for something like 13 years these dynamos and lamps have been running, being to-day seemingly as good as ever. Thirteen years in a progressive age is a long period in the history of a progressive town. The period has seen the development of the incandescent lamp, not to speak of the improvements in dynamos and alternators, and Blackpool came to the conclusion a year or two ago that what was good at the end of the seventies might be somewhat old-fashioned in the nineties, so a provisional order was obtained in 1890. For 18 months the matter was left in abeyance; then came a period of activity. Sanction was obtained for borrowing money for a central station and lighting work, plans were approved, and Mr. Robert Hammond became consulting engineer and contractor for the generating and distributing plant. The buildings are from designs submitted by Mr. Hammond and plans prepared by Mr. J. Wolstenholme, the borough surveyor, and have been carried out by Messrs. Whitehead, Mr. Hartley, Messrs. Kay and Son, and Messrs. Walmsley. The site of the station is adjoining the sidings of the Lancashire and Yorkshire Railway, and near the centre of the area of supply, giving two advantages in the easy and economical carriage of coal and reducing the initial cost of mains. We are quite sure that many of the engineers who were present at the opening ceremony envied the possession of so commodious a set of buildings. The engine-room is 125ft. long by 54ft. wide. Across this room is a travelling crane, by Carrick and Ritchie, of Edinburgh, to lift 10 tons. A plan of the engines and dynamos contained herein is given, there being already in work one 200-h.p. engine driving by

Engine and Dynamo Room—Blackpool

ropes one 100-kilowatt Lowrie-Hall alternator, two 100-h.p. engines each driving a 50-kilowatt alternator, and three 60-h.p. engines each driving a Brush dynamo for the arc lighting circuits. Room is left for other plant which is to be put in for driving the electric trams; when this is done the old tramway station will be closed. At present the plant is capable of supplying 12,500 8-c.p. incandescents and 165 arc lamps, each 2,000 c.p. nominal. Unless our memory is at fault, we understand that the whole of the arc lighting plant is fully loaded, while from one-fourth to one-third of the incandescent plant is required. The following details of the machinery have been supplied to us by the contractor.

Engines.—The type of engine selected is that known as the horizontal, coupled, compound, non-condensing, those erected in these works having been manufactured by Messrs. John Fowler and Co., Leeds, the size adopted being considered a suitable unit to work in sections, having where the strength of the plant has been subordinated to economy. The strength of the crankshaft and the length and surface of the bearings are also notable features, as are also the size and weight of the flywheel. Great care has been exercised in providing for the lubricating arrangements; the supply of oil being regulated, caught after first use, conveyed to a suitable reservoir, filtered, and used again, thus greatly economising this too often fruitful source of waste. The engines are securely railed in, and between the foundation pillars and over the pipe trenches chequered iron foot-plates are placed, giving the whole a very neat appearance. The flywheels are all grooved for rope-driving, this being found the most easy and economical method of working. The ropes on the 200 h.p. engine are 1½in. diameter, and are eight in number. Details of the two 100 h.p. engines are as follows: Speed, 120 revolutions; high-pressure cylinder, 11in. diameter; low-pressure cylinder, 18in diameter; stroke, 20in.; flywheels, 10ft.



Lowrie Hall Alternators Blackpool

regard to the varying load. The speed of the largest engine is 90 revolutions per minute, and the ordinary working load 200 i.h.p., at a steam pressure of 125lb. per square inch, but the engine is capable, by increasing the steam pressure to 140lb., of working up to 250 i.h.p. as a maximum load. This is one of the many central-station requirements already alluded to—viz., the existence of a good margin which may be safely called upon whenever it may be necessary to provide for an emergency, a point often overlooked in electricity works design. The chief dimensions of the 200-i.h.p. engine are: High-pressure cylinder, 15in. diameter; low-pressure cylinder, 24in. diameter; stroke, 30in. The slide bars and the cross-head shoes have extra large wearing surfaces arranged on each side of the connecting-rod, and are made in such a way that easy adjustment is possible without any complications. Another point in these engines worthy of note is the massive character of the bed-plate, a characteristic not found diameter, grooved for six 1½in. ropes. The details of the three smaller engines are as follows: Speed, 150 revolutions; high-pressure cylinder, 9in. diameter; low-pressure cylinder, 14in. diameter; stroke, 16in.; flywheel, 6ft. diameter, grooved for six 1½in. ropes.

Alternators and Arc Dynamos.—(*a*) One 100 unit alternator of the Lowrie Parker type. The electrical working pressure is 2,000 volts, at a speed of 375 revolutions per minute. (*b*) One 50 unit alternator of precisely the same build as the above, to give 2,000 volts at a speed of 500 revolutions per minute. These two machines were made by the Electric Construction Company, Limited, Wolverhampton. (*c*) One 50 unit multipolar alternating-current dynamo of the Hall Hammond type, having the most recent improvements, and manufactured by Messrs. John Fowler and Co., Leeds. [We understand that this is the first of these improved alternators in use.] All these machines have been specially constructed to

synchronise or run in parallel with each other at all loads. The field magnet and armature conductors do not carry more than 2,000 amperes per square inch of section, thus allowing a good working margin. Uniform with all the rest of the work, and in order to provide for the perfectly safe working of the plant at every point, the terminals to which the high-tension mains are connected are securely boxed in by polished wood lagging, so that they cannot be touched except by the proper official. The exciters for these alternators are driven by ropes from a grooved pulley on the alternator shaft, and are each of ample size to generate current sufficient to easily excite the fields of the corresponding alternator at full load. The bearings are all of good length and have large surface, and are, moreover, each provided with a water-jacket and water fittings for use in emergencies. The arc lighting dynamos, of which there are three, are capable of lighting 55 arc lamps, taking 10 amperes, and each of 2,000 nominal candle-power when driven at a speed of 800 revolutions per minute. They are of the Brush type, and are fitted with the most recent improvements for adjusting the collecting brushes, and for working at a pressure of 3,000 volts with a minimum amount of sparking at the commutator. All the alternators and arc dynamos are provided with slide rails, by which they can be moved to regulate the tension on the ropes.

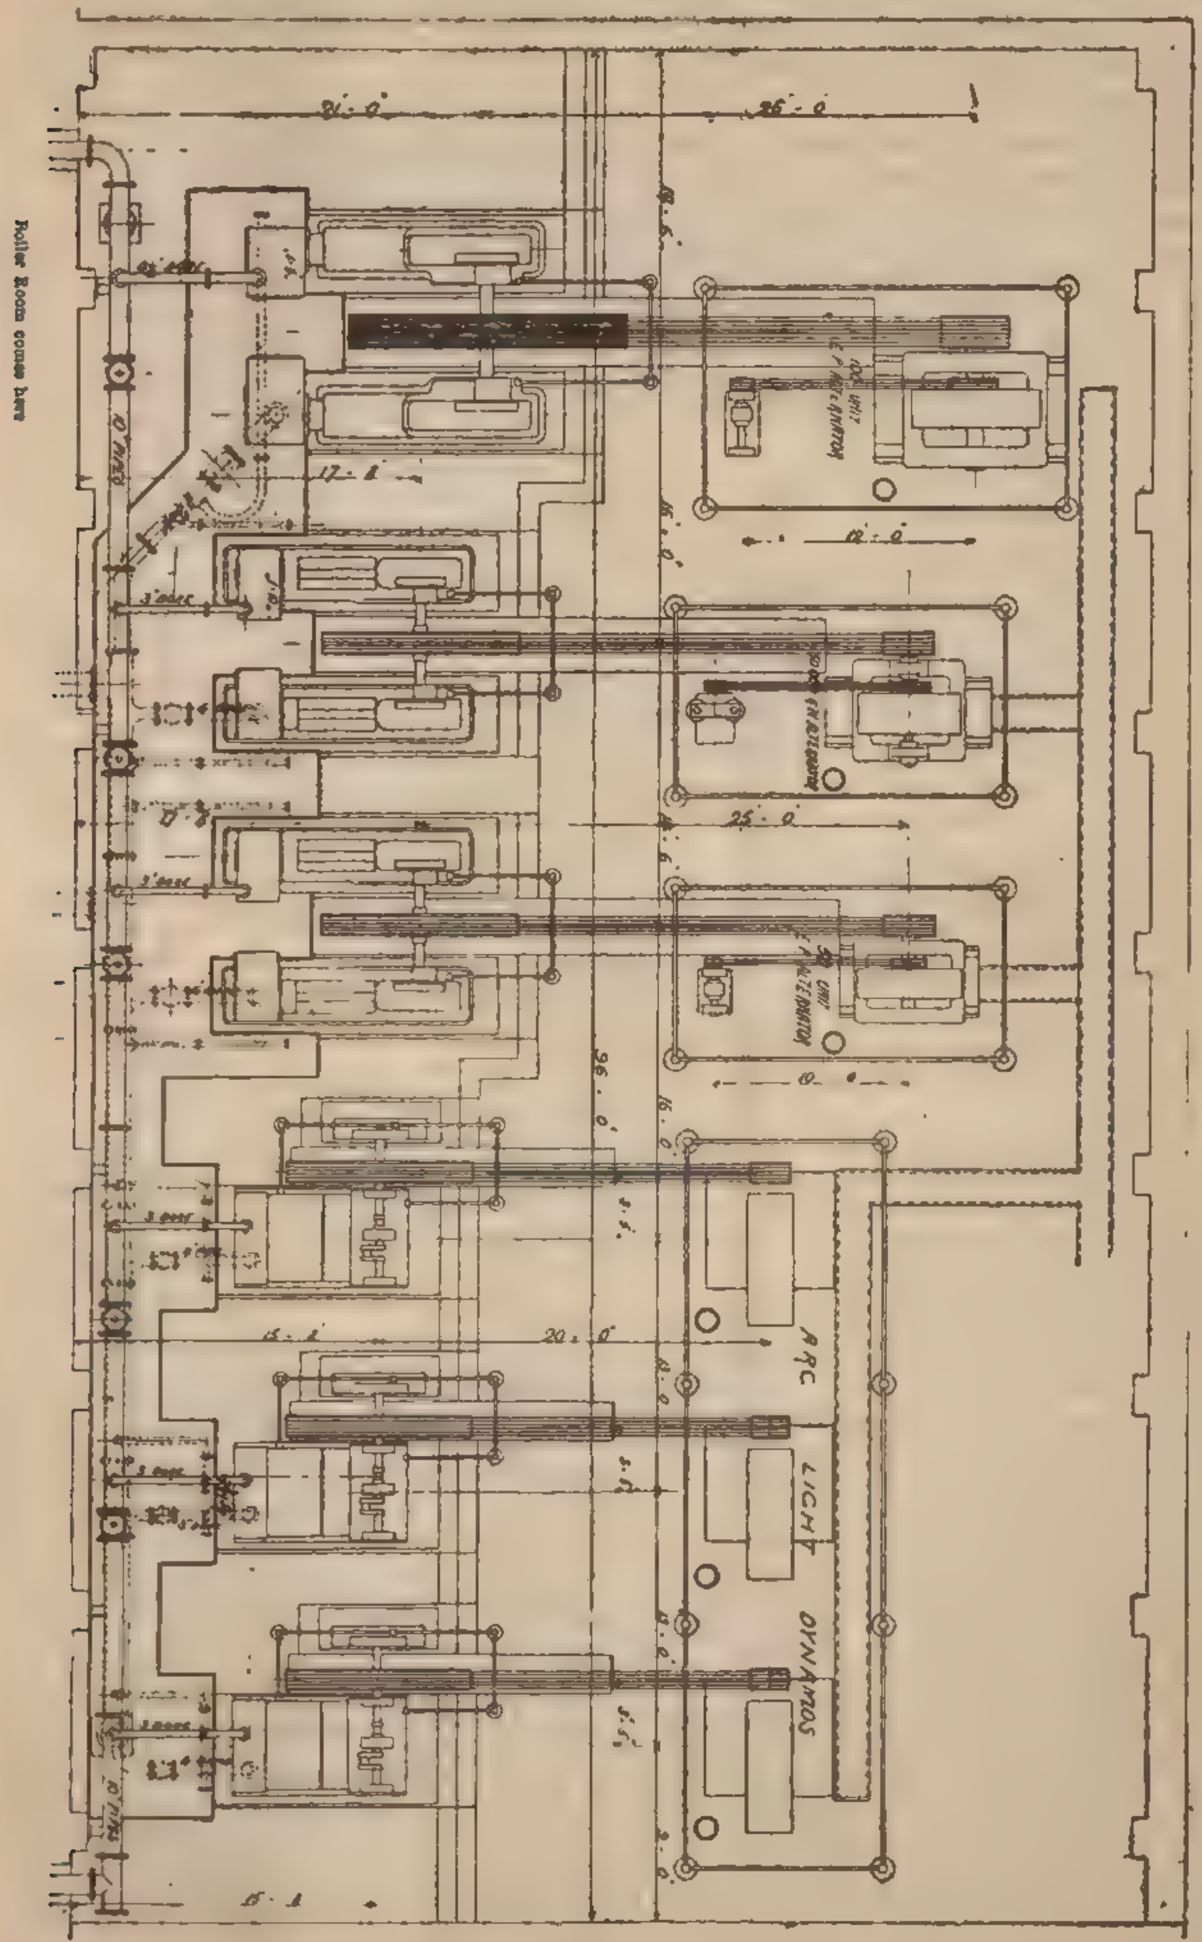
The boiler-house is 124ft. long by 54ft. wide, and in it are placed three Lancashire boilers, made by Messrs. Galloway, Limited, Manchester, each 28ft. long by 7ft. diameter, constructed for a working pressure of 140lb. per square inch. A plan of part of the boiler-house with the boilers is given herewith. They are fitted with Proctor's mechanical stokers. These are worked by means of a small engine, driving by a belt on to a line of shafting, and from thence on to the actual stoker's shafts by ropes in the usual way. Meldrum's special appliances for producing a forced draught, so as to assist the combustion of coal at times of heavy demand, are fixed on two of the boilers. The third is fitted with Proctor's moving fire-bars. Two feed-water heaters are also provided.

A very careful but simple arrangement of pipes, rendered necessary by so many auxiliary parts of the plant, including all the requisite pipes to and from the engines, feed-water heaters, pumps, tanks, etc., has been neatly worked out. An auxiliary steam-pipe is provided for supplying the pumps and stoker engine, independent of the main steam-pipe. The donkey pumps for feeding the boilers are of the duplex ram type, each of sufficient capacity to feed two boilers when working at their full power. The main steam-pipes are connected up in the form of a ring, to which both boiler and engine branches are connected, thus providing two ways by which the engines can be supplied with steam. These pipes are provided with a suitable number of stop valves placed between engine and boiler. The pipe forming the main steam-ring is 10in. diameter, and is carried on brackets fixed to the wall of engine-house. The branch pipes to the engines are of wrought iron with wrought-iron flanges. The whole of the steam-pipes were tested by hydraulic pressure to 300lb. per square inch after erection in the works. The exhaust-pipes lead off from under the low-pressure cylinders, and a stop valve is provided to each engine exhaust to shut it off from the main exhaust-pipe. Valves are arranged so that the whole or part of the exhaust steam can be turned through the heater or direct into the atmosphere through the roof of the boiler-house.

Distribution.—The distribution of electricity is effected by means of stranded copper cables, insulated with vulcanised indiarubber and laid in a specially designed system of pipes combined with service and junction boxes. Each junction-box has a loose cover, held in position by a wrought-iron clamp. The culvert connection from the box to the consumer is made by a wrought-iron pipe. The surface boxes are in all cases placed at the corners of the roads, and in the case of a long straight run they are placed at distances of 80 to 100 yards apart. The surface boxes are made in two parts, the bottom part being permanent and the upper part with the cover being adjustable, so as to allow its surface to be raised or lowered as the road level may vary, the lid being filled in with wood, macadam, or pavement, according to the construction of the road. From the surface boxes the cable can be drawn in or out as required. Where passing round corners the cable is placed on a revolving drum, which entirely prevents the possibility of abrasion. The jointing of branch cables for consumers' premises is done by cutting away part of the insulation of the main cable, which consists of indiarubber in the junction or surface boxes, and soldering the copper conductor to the conductor of the branch cable. The joint is then lapped over with rubber to the full thickness of the original insulation, and vulcanised on the spot, and the cable well taped and mechanically protected. The farthest distance at which current is at present being supplied is about two miles from the works, the length of cables laid being over 14 miles. At suitable points throughout this system the manholes break up the cables into sections, and afford easy means of stopping the mains for tests and inspection when desired.

The lamp pillars, which are of cast iron, are 25ft. high, having the arms of the borough upon a panel. The columns are fluted, and have an octagonal base which is highly ornamented. The upper part of the pillar is of uncommon description, the lamp being contained under a canopy with ornamental carriers on each side. The design as a whole, including the carrier and dome, is very much after what is to be seen in Paris, and the instructions given to the makers (Messrs. George Smith and Co., of the Sun Foundry, Glasgow, and 199, Upper Thames-street, E.C.) by the Blackpool Corporation were that the Parisian pillars should be worked to as nearly as possible. There is a large root to the pillar, 3ft. 6in. to 4ft. long, the object being to provide against the great strains met with through the severe storms which prevail locally. The pillars were greatly admired, and many people would concede the claims of the makers that they are almost, if not quite, the most handsome in existence.

The arc lamps are of the Brockie-Pell type, manufactured by Messrs. Johnson and Phillips. These lamps are so well known and have obtained so great a popularity that further description here is needless. The spectacle of some hundred or more of these lamps illuminating the whole length of the promenade, a length of between two and three miles, was magnificent. The lamps are 2,000 c.p. nominal, and placed about 50 yards apart. One minute on Friday night we had darkness, the next the whole of the lamps were flashing out their radiance, and making the Blackpool front the best-illuminated promenade in—yes, we thoroughly believe the best in the whole world. There may be a few shorter lengths with a greater concentration of light, but here, all along, the light is ample; and if Blackpool desired, she has attained her desire of the best-lighted promenade that can be seen. As an additional attraction to inaugurate the opening of the station, the authorities had arranged a kind of gala time, during the evenings of which not only was the promenade lighted as we have described, but the nearly-completed Eiffel tower was festooned with incandescent lamps lent by the Manchester Edison-Swan Company, and crowned with a projector loaned by Messrs. Clark Chapman, of Gateshead-on-Tyne. This illumination was fully appreciated, and the outline of incandescents with the flashing of the projector made a pretty sight. Before referring to the opening proceedings a word may be given as to the prospects of the station. That they are very favourable will already have been gathered, but we think that not only are they favourable, but that success is certain. Enquiring, as journalists are apt to do, about the amusements of the town, we were directed to the Opera. Of course all electrical engineers tend towards good singing—witness the success of our Electro-Harmonic, under the able guidance of Mr. Gatehouse and his colleagues. But this is a digression. The Opera House was found to be part and parcel of the Winter Gardens, a place of renown and of pleasure, under the management of that most energetic of entertainers, Mr. William Holland. The demand of Mr. Holland for lighting is fairly large for a small town. He takes current for 40 arc lamps, and for about 1,000 incandescents, each of 16 c.p. to 50 c.p. We cannot fully describe this installation. It was carried out by the Manchester Edison-Swan Company. So far as the Opera House is concerned, however, the following description has been furnished.



Plan of Engine and Dynamo Room—Blackpool.

The auditorium is lighted by means of eight particularly chaste and unobtrusive crystal pendants close to the roof, and the decorative effect of these is enhanced by nine handsome two light ormolu and crystal brackets arranged round

the fronts of the dress circle and gallery balconies. These fittings, while having been specially designed for their particular positions, are of one general design throughout, and are really charming combinations of highly artistic brass-work and prismatic crystals, the effect of which is exceedingly pleasing.

The whole of the lamps in the auditorium are controlled by a simple arrangement of switches on the prompt side of the stage. On the stage itself only the foot and proscenium lights have yet been arranged, though for several weeks an electrolier has been in use in various scenes. It is intended, however, to use the electric light almost entirely. Floats, battens, and other stage appliances are being arranged with various coloured lamps and the necessary switches to cut off or vary the light as required—the whole will be carried out on the latest principle and in the most careful and substantial manner—so that Mr. Holland and his staff will be able to produce scenic effects such as have not been hitherto seen in Blackpool.

The whole of the installation has been laid down with the object of safety, durability, and efficiency. Twenty pairs of mains run back to a distributing room in the basement. Each main has no possible connection with another, and is controlled by patent switches and cut-outs manufactured by the contractors. These mains run to as many distributing-boards, placed conveniently, and arranged to control a definite number of lights, and by no combination of accidents can all the lamps in one department be put out at the same time. Every wire is protected by a fuse, and perfectly controlled by a switch, so that the public can have every confidence in the steadiness and continuity of the light.

It may be mentioned that in carrying out the installation about 12 miles of wires and cables have been laid down.

The work has been carried out by the contractors, the Manchester Edison-Swan Company, in a manner consistent with their reputation for excellence under the supervision of their resident electrician, Mr J B Burroughs, and an excellent staff. The Winter Gardens Company has also appointed its own resident electrician, Mr. A. Fairley.

Arc Lamp post at Blackpool.

THE INAUGURAL CEREMONY.

The official programme of Friday's proceedings was as follows, so far as electrical matters were concerned:

At 4.15 p.m., guests and other gentlemen to assemble at the Corporation electricity works—entrance from Coop-street and West Caroline street.

At 4.30 p.m., the Mayor (Alderman Cardwell) and the Chairman of the Electric Lighting and Tramways Committee (Councillor Pearson) to receive Lord Kelvin at the electricity works.

At 4.40 p.m., the chairman to introduce Lord Kelvin, after which the engines will be started at a given signal from his lordship. Lord Kelvin and other gentlemen to deliver short addresses. The Mayor to propose a vote of thanks to Lord Kelvin, and the ex-Mayor (Alderman Buckley, J.P.) to second the same. Inspection of the electric lighting station by the visitors.

At 5.45 p.m., the company to proceed to a platform on the Marine Promenade, near the north side of the Central Pier, where,

At 6 p.m., Lord Kelvin will switch on the new arc light system, to extend the whole length of the promenade, and comprise 101 lamps of 2,000 c.p. each.

At 7 p.m., dinner to invited guests at the Clifton Arms Hotel, Blackpool.

From 7 to 10 p.m., inspection of the electricity works by the public—entrance from Coop-street and West Caroline street.

Brilliant illumination of the whole length of the promenade.

The Blackpool Eiffel Tower outlined against the sky by means of thousands of electric lights, and crowned with clusters of arc lamps surmounted by a powerful search light, visible for a distance of 30 miles.

We can but briefly refer to the ceremony. From first to last everything was successful, and Mr. Hesketh is to be congratulated upon the success of his indefatigable labours. Words of praise are feeble to express the energy, the resourcefulness, and the capacity to fill every man around him with enthusiasm that Mr. Hesketh displayed, and that in the teeth of illness that would have incapacitated a less determined man. The contractors and the authorities have much to thank their able electrical engineer for, and we are sure they will be quite willing to acknowledge his great services. Assume the company assembled, the Mayor in the chair at the engine-room, Lord Kelvin on his right, a galaxy of notables all around. The Town Clerk tells of absentees, the Chairman of the Lighting Committee gives an admirable *résumé* of the history of Blackpool's work as regards electrical matters, and then the guest of the day—Lord Kelvin—rises to bid the engines start on their career—one which we emphatically hope will be long and successful. It has been our pleasure—not perhaps wholly unprofitable—to have listened at the feet of the electrical Gamaliel many a time, and yet we have failed to understand the many-sided perfectness of his character. He shines as much before a popular audience when discoursing on things of local interest as he does before a scientific audience when expounding scientific truths that are understandable only by the selected few. Lord Kelvin touched lightly upon the position Blackpool holds as regards electric lighting; how it was among the very first to adopt the new illuminant, how it is among the first to have a central station belonging to the municipality. He was clear and decisive in his rendering of the duties of municipalities. Should they become purveyors of water? Yes. Of gas? Yes. Of electricity? Yes. Of letters, telegrams, telephones? No. The municipality should be responsible for localisms, not generalisms. These views were highly appreciated and applauded. Then came the crucial moment when he asked Mr. Hesketh to start the machinery, and, lo! with one accord the massive flywheels revolved, as did the various armatures, and the installation, without a hitch, without a moment's delay, was publicly opened. After a saunter round the works the visitors made their way to a temporary platform on the promenade, from which the arc lights north and south were switched on, and, as we have previously said, the whole sea-front was flooded with light. As for the dinner, admirably served at the Clifton Arms Hotel, and the after-dinner speeches, all excellent, but of local interest rather than of national—these formed the closing scenes of an inaugural ceremony of the most successful kind.

The Siam Electric Tramway.—This tramway, to which reference has been made in previous issues, was set in operation in February last. It is a single line 3¾ miles long, suitable loops being provided at intervals. It commences at the terminus of the horse-car line near the centre of the city, and continues to the suburbs of Bang-Rak, along the new road to Bang-Mai, and then through fruit gardens to Bang ko-lem. Here a swift current sets in in the river, and people coming from the surrounding country in boats alight and continue their way to the city by the tramcars. The trolley wire is hard-drawn copper with bracket suspension, as the line is at the side of the street. Teak-wood poles are used, as they are the only kind secure from the ravages of white ants. There are six cars, and Short single-reduction 20-h.p. motors are used, one to a car, these being controlled in the usual manner by rheostat and contact-board worked from either end of the car. The generating station is at the city terminus of the line, where it connects with the horse tramway continuing through the city to the palace. There are two 80-h.p. tubular boilers, and the fuel used is sawdust. The engine-room contains two high speed engines, driving two Short 40,000 watt generators. The entire plant has given excellent results. The manager of the company is so satisfied with the performance of the system that he has placed orders for four more cars.

140 SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

SPEAK OR BE SILENT—WHICH?

It is often extremely difficult to decide whether to speak or remain silent. The old adage inclines to the latter, but a too servile following of the best instructions is apt to lead astray. We may be wrong, but the time seems opportune to discuss certain questions relating to the work and responsibilities of municipal electrical engineers. Central stations are rapidly coming into action. These central stations have been designed by consulting engineers, and are in due course handed over to the resident engineer. A close watch will be kept upon the results obtained, and the resident engineer will be held responsible for success or failure. This brings us to the question, Is it possible at any time to legitimately criticise in an adverse manner any design for a central station? and, in reply, we have come to the conclusion that under no ordinary circumstances can such criticism be justified. That may seem a queer conclusion—perhaps may be taken to imply a certain weakness; but let us examine a little more closely. Given a central station erected and opened, damning with faint praise will not lead to an alteration of the fact. Such as it is, the money having been spent, it must be made the best of. Outside critics may see that the design is faulty; that in actual results this faulty design will bear hardly against them, and in comparison with other better-designed stations must take a back seat. In the dim and distant future, as the resident engineer makes up his report, and tabulates his figures so that they may be compared with other returns, he will find his committee looking askance because the figures he gives are not so favourable as those given by this or that other station. The engineer whose results lead to the worst figures may in reality be an abler man than he whose results give the better figures, but is severely handicapped by the tools which he has to use. When we find that the cost of producing a Board of Trade unit is little more than three halfpence in some places, and as much as threepence, fourpence, and even sixpence in others, this great difference cannot be attributed solely to bad management or cost of materials, but faulty design must come in somewhere. How heartbreaking is the position of the resident engineer whose results are bad compared with those of some colleague whose materials cost about the same. We are pointing these matters out because many municipalities are going on the wrong tack. Instead of carefully examining what men have done, they throw open their work to a kind of indiscriminate competition, which not infrequently must lead to weakness of design. Human nature is human nature, and the competitors desirous of getting the work can hardly be so careful as if they were employed directly and without these competitive trammels. Therefore, while some municipalities will have themselves only to blame, they will forget their own action and impute blame to the electrical engineer who has the unfortunate task of putting balance-sheets before them. The difference of, say, one penny per unit cost for an output of a million units will probably be enough to pay two and a half per

cent. upon the total capital outlay of the producing station. It will be contended that the figures at our disposal are as yet the results of immature working, and that is so, though we fail to see how the cost per unit in a fully-developed station should increase above the cost in an undeveloped station. In other words, if a station can produce at twopence per unit when working at half or three parts its capacity, it certainly should be able to produce at twopence, or under, when working at its full capacity. The variation of figures now obtainable may be largely due to the undeveloped state of the stations, but we have the minimum cost as a guide, and the conditions under which that minimum cost is obtained. The future comfort, then, of municipal electrical engineers will depend largely upon the machinery and its arrangement as handed over to them. Economy of maintenance should play a larger part in the creation of a design than economy of initial expenditure. These are some of the views which lead to the conclusion that the proper time to criticise a design is, to use an Irishism, before it is commenced, and the improper time is ever after it is finished, that is, of course, if the criticism is to do any good. If it is only to be able to say "I told you so," why any time after completion will do. The municipal electrical engineer is going to be the ultimate arbiter as to the best systems to follow, and the sooner he realises this the better, and then we shall the sooner have him exercising a collective influence.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CARDIFF ELECTRIC LIGHTING.

SIR,—We beg to hand you copy of a letter which we have addressed to the borough engineer of Cardiff, and which we think of sufficient general interest to bring under your notice.—Yours, etc.,

S. LAMBERT, Secretary,
Callender's Bitumen, Telegraph, and Waterproof Company, Limited.

101, Leadenhall-street, E.C., October 18, 1893.

"101, Leadenhall-street, E.C., 16th October, 1893.

"Dear Sir,—We beg to confirm the telegram sent you to-day as follows:

"'Notice of your Corporation requiring tenders for cables only published in Friday's electrical papers. Tenders required to be sent in to-day. Time manifestly too short. Will you grant extension? Please telegraph reply.'

"and have received your reply:

"'Extension of time for receipt of tenders impossible.'

"Under these circumstances, we desire to lodge a formal protest against the method of inviting tenders which you have adopted, and the totally insufficient time which has been given to independent contractors to make their calculations and to prepare the necessary offers.

"We have made enquiries, and find that your Corporation has not advertised in any of the papers devoted to electric lighting, the notice to which reference is made in our telegram to you being taken from the press outside the electric industry.

"We call your attention to the fact that this is the first contract for electric cables 'advertised' by a corporation which has not been fully announced in the trade journals.

"The method you have adopted in inviting tenders precludes open tendering by independent manufacturers.

"If your Corporation had decided to invite certain makers to a private competition we would have had nothing to say, but we distinctly protest against action such as has been adopted in the case of Cardiff being considered as a public invitation to tender.

"We reserve to ourselves the right to make this letter public.—Yours faithfully,

"Callender's Bitumen, Telegraph, and Waterproof
"Company, Limited,
"T. O. CALLENDER, Manager.

"W. Harpur, Esq., borough engineer,
"Town Hall, Cardiff."

THE TESTING OF INSULATED WIRES.

A series of tests of insulated wires is being made at the Chicago Exhibition by a sub-committee, consisting of Profs. Owens, O'Dea, and Jackson.

The wires entered for the test are the okonite, kerite simplex, Grimshaw, and those of the India Rubber Comb Company, Washburn and Moen Manufacturing Company, and the Western Electric Company. We learn from the *Electrical Engineer* of New York that the wires will be subjected to the usual tests for resistance, insulation, and electrostatic capacity. In addition to this, however, they will undergo a breakdown test to determine at what potential the insulating material suffers puncture from the applied E.M.F. The method employed for this test is almost identical with that which has for some time past been in use at the works of the Westinghouse Electric and Manufacturing Company. Indeed, the apparatus employed by the judges has been placed at their disposal by the Westinghouse Company for this purpose. The current required to break down the wires is obtained primarily from a 100-volt alternating circuit. This is first passed through a safety switch, and then through a special double-fuse block. In arrangements of this nature it is, of course, necessary to prevent the high tension from reaching ground or the primary, and hence the insulation of the high-tension and other transformers must be carried out in the best possible manner. In order to prevent the high tension from breaking through insulation and getting back into the 100-volt primary circuit, a special "insulating converter" is employed. This converter consists of a primary connected to the 100-volt circuit, with four secondary coils, each giving 100-volt tension, all included within the same converter-box. The terminals of these 100-volt coils of the converter pass through switches and into the primaries of four high-tension coils, each capable of raising the potential to 15,000 volts. In addition to this there are two additional high-tension transformers of 2,000 volts each. Three of the 15,000-volt converters are not regulable, but one of them can be thrown on in steps of 3,000 volts each, while the 2,000-volt converters are graduated in steps of 100 volts. The readings are taken by means of a Thomson electrostatic balance reading up to 100,000 volts. The wires, of a uniform length of 6ft., have 3ft. of their length inserted in a tank full of water, the insulation, of course, extending above the surface. One terminal of the high-potential converter sets is connected to the tank, and the other terminal to one end of the wire to be tested, the other end of the latter being left free. Beginning with the lowest potential, the pressure is left on for 10 seconds. If the wire stands it, the next higher pressure is put on and so on, each potential being applied for 10 seconds. The current is thrown on with the safety switch; when the insulation breaks down the fuse blows. This arrangement has proved very satisfactory, and very rapid work can be done with it. In addition to the breakdown tests, it has been suggested by Prof. Barrett that it would be highly desirable to test wires after having been subject to the action of acids and ammonia as well as plaster. Although not definitely determined upon, it is probable that, with the aid of Prof. Barrett, a series of such tests will be carried out.

ELECTRIC SUPPLY COMPANIES.—I.

(Continued from page 341.)

WESTMINSTER ELECTRIC SUPPLY—ECCLESTON PLACE STATION.

The Eccleston-place central station of the Westminster Electric Supply Corporation is situated out of Eccleston-street, behind the Buckingham Palace-road, not far from the Victoria railway station. It is at this station that the Westminster Supply Corporation have their central offices—a handsome, lofty, and well-fitted suite of rooms. The system of supply is the same as the other Westminster stations—direct-current, three-wire distribution, with accumulator service at 100 volts.

The area of supply extends from Hamilton-place, Piccadilly, on the north, to the banks of the Thames at Vauxhall, on the south. It includes the favourite and fashionable districts of Hyde Park, Belgrave-square, Eaton-square, and other squares and streets in Belgravia, including Buckingham Palace, down to Chelsea Bridge, and away east to Vauxhall Bridge.

The engineer staff is as follows: resident engineer, Mr. C. O. Grimshaw; assistant engineers, Mr. W. Thompson and Mr. Garstin. The working staff consists of 19 men, composed as follows: three switchboard hands, three engine drivers, three assistant drivers, three firemen, two coal-trimmers, one battery attendant, one carpenter, and three general hands. The staff work regularly in three shifts of eight hours.

STATION.—The construction of the station is the same as that of Millbank-street, the building having been designed by the same architect for similar arrangements. The lofty engine-room is lined with white glazed bricks; the room above with concrete floor on girders, serving as workshop.

The size of the engine room is 93ft. by 38ft. The boiler-room at the side is 66ft. by 41ft. The accumulator-room is above the boiler-house and of the same size. There is ample room for doubling the plant in the present building; and there is space behind, 100ft. by 76ft., for more than doubling the present size of the entire station.

The concrete engine foundations are formed in one block 10ft. thick, but where space is left for other plant it is 2ft. less, so that the foundation bolts may be let in without disturbing the present foundations by simply filling up with concrete. The whole station is fitted with fire hydrants, and there is a 10-ton travelling crane overhead. An engineer's office occupies one corner of the engine-room. The switchboard, a very fine piece of workmanship, stretches along the wall on one side above the engines and dynamos. The engine-room is lighted by two 200-c.p. Sunbeam lamps in the roof, and several 16-c.p. lamps.

The chief difference between the Eccleston-place central station and that of Millbank-street lies in the boilers, the type of some of the engines, and of condensing apparatus.

BOILERS.—The boilers at Eccleston-place, instead of being of the water-tube type, are modified marine boilers. There are in all four boilers—three by Davey, Paxman, and Co., and one by Fraser. The gases in these boilers go into a combustion-chamber at the back, and are led forward through tubes to a smoke-box in front of the boiler, and then round the sides back into the main flue. The grate surface is 30 square feet, and the steaming capacity 5,000lb. of water per hour. The steam pressure is 150lb. per square inch.

A Green's economiser is used for heating the feed-water. What little water is required to keep up the condensed water to the necessary amount is obtained from the Chelsea water-mains, and a tank for this purpose is fixed above the pumps.

Duplicate steam-pumps, as at Millbank street, are used for the feed-water, and there is a double set of feed-pipes to each boiler. All water used in the boilers is pumped through a special water-meter.

The coal is the same as before mentioned—best Welsh smokeless—and is weighed on being brought in by the carts, on a roadway weighbridge, and again at every watch each barrowload is weighed on a portable weighing machine, and an exact record of the amount of coal burnt and of water used is kept for each watch.

ENGINES AND DYNAMOS.—The engines are of the Willans and Davey-Paxman make, and drive Crompton, Siemens, and Elwell-Parker dynamos.

There are three Willans II engines—triple-expansion, 200 i.h.p. each—one of which has just been put down in extension of the plant. Two of them drive Crompton dynamos at the speed of 350 revolutions. The third drives an Elwell-Parker machine.

Two Davey-Paxman "Windsor" engines of 150 h.p.—vertical, compound—also drive smaller Crompton dynamos; and two Willans G G engines—90 i.h.p.—drive Siemens dynamos, the latter being used as balancing machines on the three-wire network. All the dynamos are coupled direct to the engines, and are mounted upon the same bed-plate therewith.

The following are the details of the dynamos: The two large Crompton dynamos are 112 units, shunt-wound, four-pole machines, with drum armatures, giving 500 amperes at 225 volts; the two smaller machines (driven by the Davey-Paxman engines) are of the capacity of 250 amperes at 225 volts. The new Willans engine drives an Elwell-Parker two-pole dynamo of 112 units. The two Siemens machines give 300 amperes at 135 volts running at 430 revolutions. Ordinary sight-feed lubricators are used throughout.

All these sets of steam dynamos are under perfect control, are very economical, take but little room, and start very quickly—qualities the most desirable in central-station work. During a sudden fog the station can be started from complete shut-down within five minutes.

The condenser is placed in one corner of the engine-room, beneath the level of the floor, and serves for all the engines, all the exhausts being brought into one large steam-pipe. The ordinary type of surface condenser is used, made by the Central Marine Engine Works, the air-pump being placed alongside.

SWITCHBOARD.—The switchboard is of the same massive type as at Millbank-street, but has seven feeders in use, with capacity for eight. Pilot wires are brought back from every feeding point. The accumulator-room here being immediately behind the engine-room, the connections are made direct to the switchboard. The voltage on the houses is kept steadily at 100 volts.

Two recording voltmeters record the voltage continuously on each side of the circuit. Each dynamo has its meter, and two special Aron meters are connected with the batteries, one between positive main and the third wire, and the other between third and negative. These meters are made reversible, and register the difference of charge and discharge.

A potentiometer set, placed alongside the switchboard, mounted in a wooden case, is used for calibrating the instruments or for testing direct the potential at any point.

AN IMPROVED FORM OF INSTRUMENT FOR THE MEASUREMENT OF MAGNETIC RELUCTANCE.*

BY A. E. KENNELLY.

Of the methods that have been adopted for the measurement of magnetic permeance or reluctance of iron, the Faraday ring test with ballistic galvanometer is generally admitted to be the most accurate and reliable. It is, however, essentially a laboratory measurement, requiring considerable time in preparation, execution, and computation. For workshop measurements and comparisons, tractive and magnetometric methods have been employed with a convenience and facility usually obtained at some sacrifice in accuracy. Recently instruments have been used with success in which the reluctance of a sample bar of iron is compared with that of standard bars of soft Norway iron, notably the magnetic bridge of Mr. Thomas A. Edison exhibited at the Paris Exhibition of 1889, and the differential magnetometer of Mr. R. Eickemeyer. It is proposed to here describe a new instrument of this class, for which certain advantages may perhaps be claimed.

Fig. 1 represents the well-known galvanic arrangement of circuits in which two resistances, R_1 R_2, can be compared

* A paper presented to the Electrical Congress at Chicago.

by a null method. E_1 and E_2 are two equal and constant E.M.F.'s inserted in the conducting paths, A B and B C, of equal resistance. The galvanometer, G, connecting the junction, F, of resistances with the junction, B, of E.M F.'s will indicate no current when R_1 and R_2 are equal. The conductor, F B, corresponds to the neutral wire of a three-wire system of electrical distribution.

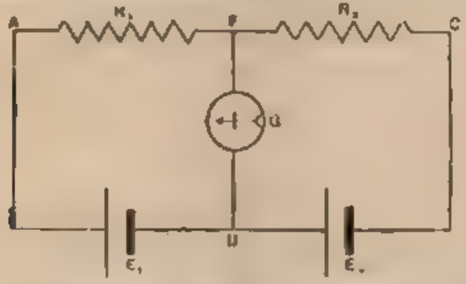

Fig. 1.

Fig. 2 represents the corresponding condition of magnetic circuits. A B C is a stout vertical frame of annealed Norway iron with two coils, M_1 M_2, wound with the same number of turns of wire, connected in series so as to develop with regulated constant current strengths equal definite M.M. forces. The upright G corresponds to the galvanometer arm in Fig. 1, while the bars, A F and F C, are test pieces of iron having a cross-section considerably smaller than that in the remainder of the circuit. One, A F, suppose, is a standard section made up of one or more bars of soft iron whose quality is known, while the other, F C, is the bar whose reluctance is required.

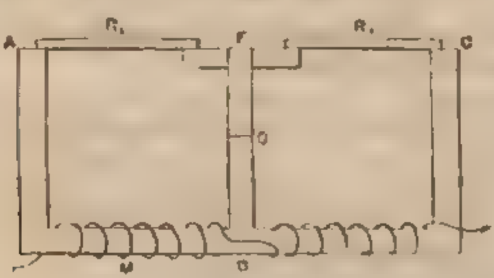

Fig. 2.

If the two reluctances, R_1 R_2, are equal, the magnetic potentials at F and B will be equal, and the bar, G, will remain unmagnetised when the coils, M_1 M_2, are excited. On the other hand, if R_1 and R_2 slightly differ, the potentials at F and B will not coincide, and magnetic flux will traverse the bar, G. Since the magnetic circuits are all closed, the leakage through the surrounding air will be

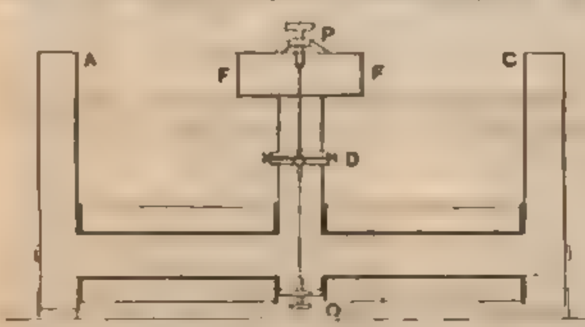

Fig. 3.

symmetrical and usually negligible, so that calling the flux through the main circuit Φ, and that through G, ϕ.

$$\phi = \Phi \frac{R_1 - R_2}{R_1 + 2G}.$$

In order to ascertain whether flux did traverse the bar G, we might, according to established principles,* cut in imagination an indefinitely narrow gap or crevice through G in a horizontal plane, and insert therein a magnet pole with apparatus to measure the tractive force to which it would be subjected. As the nearest practical approach to this plan, we can cut a gap across G $\frac{1}{16}$in. (0·16 centimetre) wide, and swing in the crevice a flat disc armature, carrying a steady feeble current and with an attached pointer or index close to a fixed scale. We then obtain in all essential features the instrument here to be described.

Fig. 3 represents to scale in front elevation the actual instrument. D is the disc armature, wound with 100 radial wires from centre to circumference. Half of this disc is always covered by the pole-pieces above and below it. The unifilar suspension attached to the points P and Q supplies a current of about 10 milliamperes to this disc. A sensibly constant tension upon the suspension is obtained by means of a spiral spring within the lower slide tube, and it can be readily shown by experiment or computation that small variations in the tension of such suspensions have a very small influence upon the torsional moment.

The *modus operandi* is as follows: A sample strip or flat bar of the iron to be tested is laid across the gap, F C. The breadth of the bar being conveniently 1in. (2·45cm.) and the height ½in. (1·27cm.), strips of soft iron to match this are laid across the gap, A F, in parallel, each being, say, 1in. by ⅛in. (2·54cm × 0·318cm.). If the disc circuit is then closed, and if there is no appreciable residual magnetism in the apparatus, the disc will remain uninfluenced and its index at zero. The field magnets are now excited in series with a suitable and measured current. The disc and pointer will now move to one side or the other about the axis of suspension according to the preponderance of reluctance between the two sides, and soft-iron strips have to be added or removed across A F until balance is restored. Generally balance will be found between two adjustments of cross-section at A F, and the proper amount can then be computed by proportional parts.

Steinmetz has shown* that from a series of such adjustments to equality between standard and sample bars at various excitations, the complete hysteresis curve of the sample can be deduced through the known valuations of the standard; but since a linear relation is found to exist between the reluctivity and magnetising force in iron above the critical intensity, two such observations are theoretically sufficient to determine the reluctivity of the sample for supra-critical magnetising forces.

The instrument can also be employed to readily indicate the retentiveness of sample bars of hard iron or steel. If after a balance has been obtained at a noted excitation, the excitation be withdrawn by interrupting the circuit of the coils, M_1, M_2, and the standard bar is removed, the residual flux from the test-piece will, disregarding some slight loss by leakage, pass entirely through the air-gap and disc at D. If the constant of the disc has been determined independently, the deflection of the pointer for the observed current through the disc will supply the amount of this flux.

If N denotes the number of turns in each spool;
I the current strength exciting the spools (amperes);
l the length of the test bar (cms.);
g the reluctance of the air gap at the disc (C.G.S.U.);
H_1 the magnetising force in the bar during excitation;
H_2 the magnetising force in the bar with excitation;

then the M.M.F. of excitation is in each coil $\frac{4\pi}{10}$ N I, and since the intensity in the test bar is considerably greater than in the field frame, the magnetising force brought to bear upon the test bar is nearly $\frac{4\pi}{10}\frac{N I}{l}$. After removing the excitation and standard bar, the observed residual flux encounters at the air-gap a reluctance, g, so that neglecting the comparatively small hysteresis of the soft-iron field frame, the counter M.M.F. at the gap is $-\Phi g$, representing an average demagnetising force in the bar of $-H_2 = \Phi g / l$ nearly, so that the relative values of flux density are readily found with different sample bars for any selected value of H_1, or, more closely, for any consequent ranges of $H_1 - H_2$.

By mounting two opposed parallel plane iron plates between the uprights, A and F, in such a manner that the length of air-gap between them can be adjusted by a screw, it becomes possible to measure the reluctance of a bar placed

* Clerk Maxwell, "Electricity and Magnetism," vol. ii., par. 396.

* *Transactions* of the American Institute of Electrical Engineers, vol. ix., p. 33, January, 1892.

between F and C by direct comparison with the reluctance of air. Trial has shown, however, that the additional contact surfaces involved the dissymmetry introduced into the two sides of the circuit, and the uncertain leakage error with large air-gaps probably more than offset the advantage to be derived.

The errors attending the use of the instrument are: (1) The variability of reluctance in the field frame; (2) errors in estimating the reluctance of the contact surfaces and the effective length of the test bar.

The first source of error depends upon the hysteresis in the iron of the field frame. It can be reduced to small limits by keeping the cross section of the test bar a sufficiently small fraction of the cross-section in the frame, thus bringing nearly all the reluctance of the circuit into the test bar. A correction can also be made for the outstanding frame reluctance.

The second source of error is common to all forms of permeameters in which straight test bars are employed in closed magnetic circuits. There will be a certain range of reluctance in the contact surfaces that can be kept in subjection by giving to those surfaces adequate area. There is also the more complex error due to misestimation of the effective bar length, for the reluctance of the bar will not only be encountered in the distance between the supports, F and C, but also by some portion of the length resting on the supports. The virtual length of bar included in the circuit will thus be a function of the intensity within it, and will not generally be the same for the test and standard bars.

The advantages of the instrument are: (1) Absence of hysteresis in the moving and indicating parts, which contain no iron; (2) great sensitiveness and control; (3) small reluctance in the narrow air-gap or path of differential magnetisation; (4) convenience in comparing retentive powers in steel.

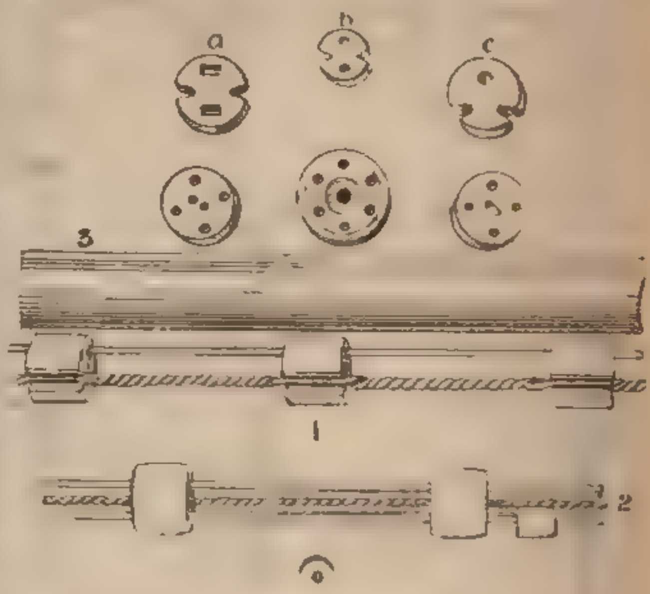
The writer desires to acknowledge his indebtedness to Mr. Thomas A. Edison, in whose laboratory this instrument was constructed.

The dimensions of a completed instrument are appended in detail: Core diameters, 5·08cm; core cross-section, 20·3 square centimetres; uprights, 5·08cm. by 5·08cm.; cross-section of uprights, 25·81 square centimetres; disc diameter, 7·6cm. external; entrefer, 0·16cm.; approximate reluctance of entrefer, 0·00826 C.G.S.U.; polar area above and below disc, approximate 20 square centimetres; mass of disc and pointer, 28 grammes; turns on each field spool, 3,213; diameter of suspension wire, 0·018cm.; deflection of pointer per ampere of current in disc, and per C.G.S. unit of flux through disc, 0·03deg.; thickness of aluminium disc, 0·035cm.; diameter of wire in disc radial winding, 0·035cm., silk covered to 0·042cm.; total thickness of disc, 0·077cm.; mean clearance of disc in air-gap, 0·0415cm.; winding 100 radial wires carried round on rim and re-entering at common channel, never passing into air-gap; available angular range of pointer, 140deg.

COOK, SMYTHE, AND PAYNE'S PATENT FIRE-PROOF SYSTEM OF CONDUCTORS.

These conductors were designed with the object of providing a mechanical system of conductors that would stand the same wear and tear that gas and water pipes are subject to when erected in the interiors of buildings. No vegetable substances are used in their construction and no inflammable materials. The conductors may be composed of tubes, strips, or wires placed inside tubes or tubular casings, and kept apart by means of insulators of suitable form fixed at intervals along the conducting tubes, wires, etc.

When arranged on the concentric principle a tubular strip is usually employed, to which insulating rings are fixed both inside and out. The tubular strip is not brazed nor soldered along the edges, but left open, and the rings are made to fit tightly inside and outside, so that they are held firmly in position by the mutual inward and outward pressure against the tubular strip. The inner insulators are provided with holes through which a rod or wire is afterwards drawn, the wire forming the lead and the strip the return for the current; these are then placed inside an outer tube that serves as a protection. The conductors can thus be made up in lengths in the workshop, and sent out ready for erection. Conductors arranged on this principle are very rigid, and are useful for vertical mains that may be used in large buildings to supply current to the different floors.

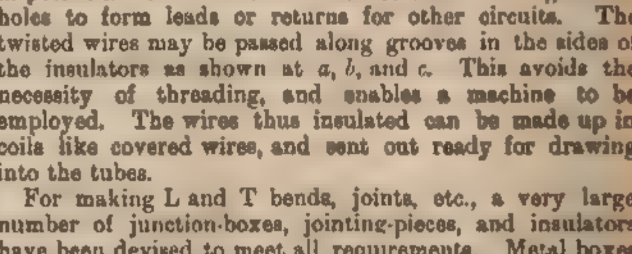


Figs. 1, 2, and 3.

Joints are made in a variety of ways by means of wires or strips soldered to the tubes. A useful plan, where the current is to be subdivided on a distribution board, is to solder the end of the tubular strip into a brass or copper ring with holes round the periphery fitted with screws under which connecting wires may be fixed for jointing to the fuses on the board.

Another method of insulating the tubes consists in the employment of small porcelain studs fitted into holes at intervals along the inner tubes. It is impossible to shift these studs out of position without breaking them.

When ordinary wires or flat strips are used, the insulators are made with one or more suitable holes through them to receive the former. If ordinary wires of circular section are employed, two are used; if a wire of rectangular section or a ribbon is used, one is sufficient. The insulators are first threaded on to the wires or strips at intervals, after which the latter are twisted, which fixes the insulators



Figs. 4 and 5.

in position. Other wires can then be drawn through other holes to form leads or returns for other circuits. The twisted wires may be passed along grooves in the sides of the insulators as shown at *a*, *b*, and *c*. This avoids the necessity of threading, and enables a machine to be employed. The wires thus insulated can be made up in coils like covered wires, and sent out ready for drawing into the tubes.

For making L and T bends, joints, etc., a very large number of junction-boxes, jointing-pieces, and insulators have been devised to meet all requirements. Metal boxes made of two or more parts—castings or stampings—and all interchangeable, may be used; these can be fitted on round the ends of the tubes, one half being usually fitted to the wall or ceiling, the other half acting as a cover that can be put on after the tubes have been placed in position, and the joints (if any) made.

L and T junctions are also used. Fig. 4 shows an L-junction for going round corners. Fig. 5 shows another made with press tools, and fixed together by means of rings, R, or clips slipped along the projecting edges or feathers that are turned up to receive them. This is shown open in Fig. 7.

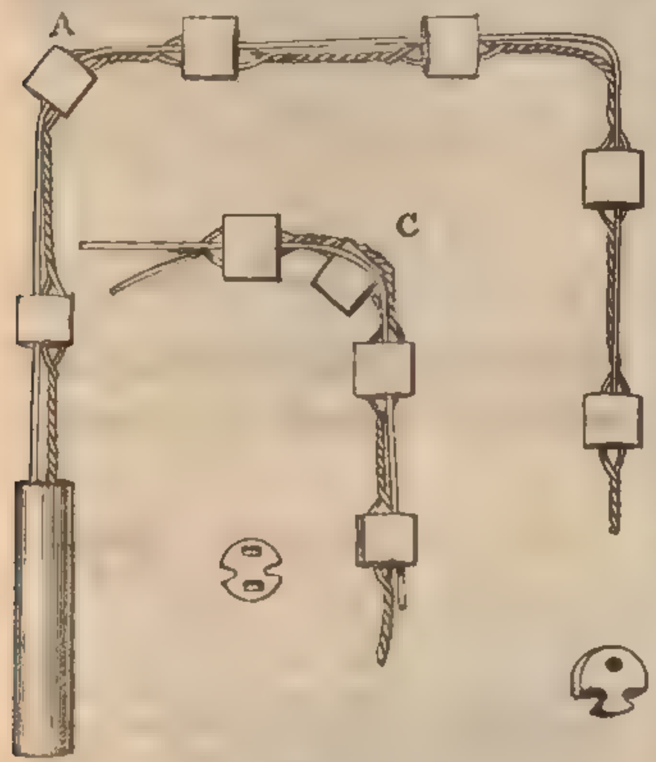


FIG. 6.

If a ring occurs exactly at a joint, as at A, Fig. 6, no further insulation is required; if not, as at B, an insulator with grooves in it may be inserted, if necessary, at C.

For very special work, where the exact position of the bend is known small rings may be threaded on to the twisted or to the other wire or wires, as at E and F.

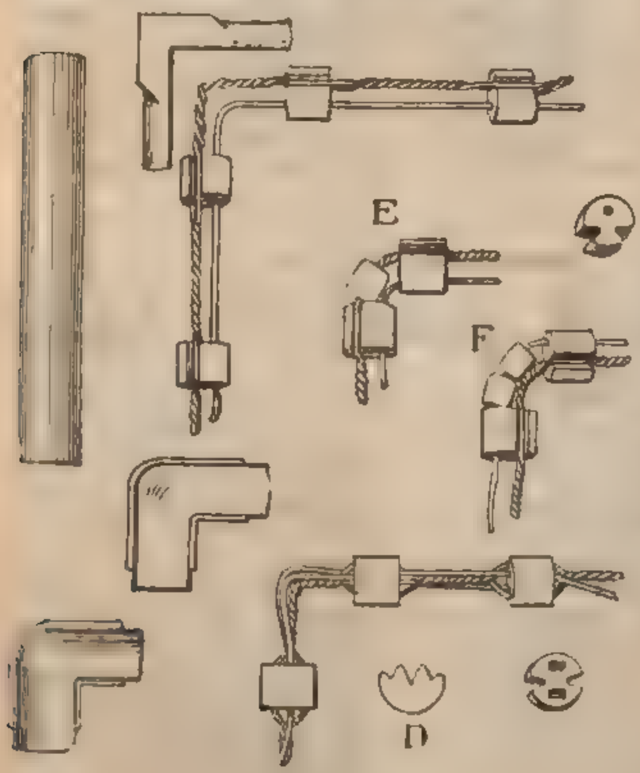

FIG. 7.

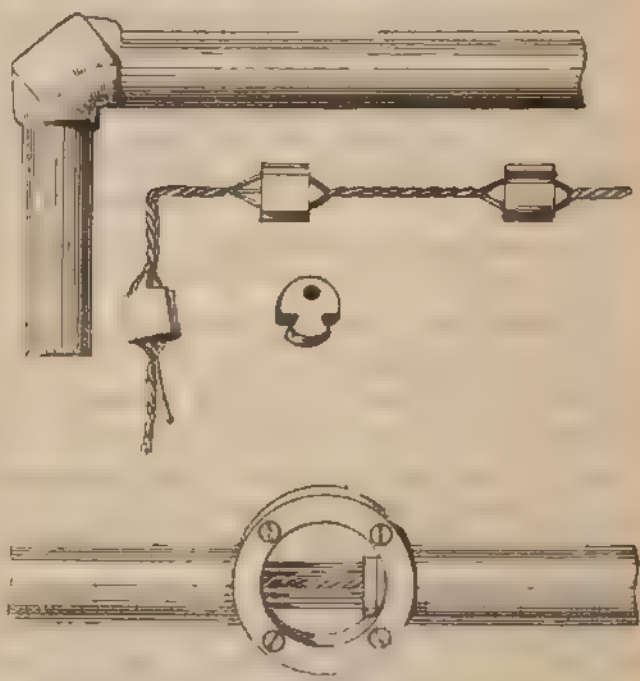
If it is desired to break the metallic continuity of the outer tube, a porcelain junction may be employed which has grooves inside that can be fitted round the wires; these are made in two parts with projections fitting inside the ends of the tubes, as shown in Fig. 8.

Fig. 9 shows another insulating junction, which acts also as a support; these are most convenient where ceiling roses are used, or other similar fittings, in combination with the tubes.

Special attention has been given to the construction of rows of lights when fixed to tubes whether fixed or portable, such as those used for showrooms and shop windows, and for the floats, battens, or lengths employed for stage-lighting. A long tube with 50 lights arranged in this manner has recently been erected in the new Victoria Concert Hall at Langham-place for lighting the orchestra.

The fireproof nature of the arrangement is one of the chief advantages claimed for the system. The conductors can also be erected in hot places—boiler-houses, engine-rooms, factories, etc.—without any risk of the insulation being injured by the heat, as is the case with rubber-covered wires.

With regard to the permanent character of the insulation the inventors wish to point out that the conditions of working where bare conductors are used for interior wiring are usually the reverse of those met with in connection with underground conduits. The temperature of a conduit is often lower than that of the air above, and when moist air finds its way into a cold conduit there may be some condensation; the interior of a building, however, is usually warmer that it is outside, and this condensation is not found to take place.



FIGS. 8 AND 9.

There are usually many places in an installation where the lamps are fixed close to or on the tubes, and when lighted acted as small stoves, keeping the tube warm and promoting circulation of the air.

When the conductors are erected in boiler-houses, or near furnaces or ovens, or laid in recesses in walls or floors near hot-water pipes, the insulation, if anything, is improved. In places exposed to the heat of the sun, and in hot countries generally, these conductors can be employed where shellac, paraffin, wax, and rubber insulation would be unsuitable.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE II.

(Concluded from page 355).

The original project for utilising the motive power of the Rhone at Geneva, partly for pumping a supply of water, partly for motive power for industry, comprised 20 turbines of 3,000 h.p. each, or an aggregate of 6,000 h.p. Fourteen of these were at work in 1892. Four more of somewhat larger size will, it is expected, be constructed by 1898. When these are at work the whole available water power in Geneva will be utilised. But it is foreseen

* Howard Lectures delivered before the Society of Arts.

that the demand for power will not then have been satisfied. The total receipts for the installation reached £22,500 in 1891, and were increasing £2 200 annually The Municipality of Geneva has determined to provide for future demands, and plans are being studied for utilising 12,000 h p at a point on the Rhone six kilometres below Geneva, whence the power will be distributed electrically. At Biberest, near Soleure, Messrs Cuenod, Sautter, and Co have utilised 360 h p., and transmitted it 28 kilometres electrically At Genoa water power due to surplus fall along a line of water main has been utilised at three stations The greater part of the energy is transmitted to Genoa for electric lighting and power purposes.

These are cases where water power has been utilised and distributed which are actually in operation; but there are many other schemes projected: one is for utilising 10,000 h p on the Drause, near Martigny; another to utilise 20,000 h.p. at a point 17 kilometres above Lyons In Sweden, there is a project to transmit power from the Dal River Fall at Mansbo, to the Norberg mining district, a distance of 10 miles; another to transmit the power of the Strup Waterfall, on the Judal river, to the town of Ostersund, a distance of 11 miles. Projects for utilising the Falls of Trollhatan, and the River Motala to supply power to Gothenburg and Nord Koeping, have also been studied

Water Power in the United States of America It is in the United States of America that water power is most largely used, where it is in most direct competition with steam power and where data for a comparison of their relative advantages can best be obtained Interesting data as to the extent to which water power is utilised in the United States are given in a paper by Mr G F Swain, and read before the American Statistical Association * The money value of the water power utilised in the United States is very considerable From the returns of the tenth census it appears that in 1880 there were 55,000 waterwheels and turbines of an aggregate of 1 250,000 h p At £5 per annum the water power utilised is worth £6,250,000 a year. The comparison of the relative amount of water and steam power is interesting Taking the whole of the United States, 36 per cent of the power used in manufacturing was at that date water power, and 64 per cent steam power

In certain industries the proportion of water power was greater In the manufacture of cotton and woollen goods, of paper, and of flour, 760,000 h p. derived from water, and 515,000 h p derived from steam, were employed In the North Atlantic division 4 81 water horse power are utilised per square mile.

Division.	Water power per cent.	Steam power per cent.
N Atlantic	43 1	56 9
S. Atlantic	49 5	50 5
N Central	22 2	77 8
S. Central	22 5	77 5
Western	35 3	64 7
The United States	35 9	64 1

Fig 12 is a map taken from Mr Swain's paper, which shows that over a considerable area of the United States the water power used exceeds the steam power It should, however, be pointed out that in the decade 1870 80, during which the total power used increased 45 per cent., 9 per cent. of the increase was due to water power, and 91 per cent. to steam power. It is possible that under the new conditions now obtaining, the present decade will show a greater relative increase of water power.

American Method of Distributing Water Power.—The method in which water power is distributed in America to a number of consumers is almost peculiar to that country A water power company is formed, which undertakes the construction of the permanent works, such as a river dam, sluices, and distributing canals. In New England there are five water power stations where more than 10,000 h p. is utilised during working hours, and 13 stations where more than 2,000 h p. is utilised The water is distributed to mill owners, who construct the turbines and pay a rental to the water power company proportional to the amount of water used The earliest application of this system was at Paterson, New Jersey, where the Passaic river furnishes about 1,100 h p night and day † At Lowell Massachusetts, the utilisation of the water power began in 1822. The Merrimac river has a fall of 35ft., and furnishes at the maximum about 10,000 h.p. during the usual working hours. At Cohoes, in the State of New York, the Mohawk river has a fall of 105ft. It could furnish about 14,000 h p during working hours, but it is only partly utilised at present. At Manchester, New Hampshire, the Merrimac has a fall of 52ft., and furnishes at the minimum about 10,000 h p during working hours. At Lawrence, Massachusetts the Essex Company built a dam forming a fall of 28ft., and obtaining a minimum power of 10,000 h.p during working hours. At Holyoke, the Hadley Falls Company built a dam forming a fall of 60ft., and rendering a power of 17,000 h.p. available during working hours

To indicate the magnitude of some of these works, it may be stated that at Lawrence the masonry river dam is 900ft. long and 32ft. in height. The cost was £50,000. From this dam two canals extend down stream, one on each bank, and between these canals and the river are located the mills, occupying the entire river front. On the north side the mills extend for a distance of more than a mile. The cost of the canal on the north side, 5,330ft. in length and 100ft. in width at the upper end, was £50,000 The canal on the south side 2 000ft in length and 60ft in width, cost £30,000 The case of Holyoke may be described in somewhat greater detail. The whole of the factories in the town are worked by water power, and the system is strictly a distribution of power to many consumers at a rental strictly proportional to the amount of power used, although the power is actually developed in the mills by turbines belonging to the millowners The first weir or dam was built in 1847, but it was carried away. A second dam of cribwork was built in 1849. In 1868 an apron was constructed to protect the rock immediately below the dam, since then, Mr. Clemens Herschel * has carried out extensive repairs of the dam under conditions of singular difficulty and with great success. The structure is now 130ft. in width, 30ft. high and 1,019ft in length From above the weir a first canal supplies water to the highest line of mills. From these mills, after driving turbines, the water is discharged into a second canal, which is a supply canal to a second line of mills. The tail races of these mills discharge into a third canal feeding a third line of mills and there are still other mills worked by the water before it returns into the river. The power now utilised is 15,000 h p. by day, and 8,000 h p. at night. Altogether there are about 53 mills

With the grant of land for a mill there was leased the right to use a definite portion of the water. A "mill power" is defined as 38 cubic feet of water per second on a fall of 20ft during 16 hours per day. This gives about 63 effective horse power on the turbine shaft. At the time when Mr. Herschel became engineer to the water company the water was used extravagantly By

Fig 12.

introducing a system of testing the turbines, and by establishing gauges at each mill showing at any moment the amount of water passing through the turbines great economy in the use of the water was secured. The water saved was sold for surplus power. Observations of the amount of water used by each turbine and the difference of the level in the head and tail race are made once in the day and once at night. Three inspectors are engaged exclusively in this work. From the daily observations the amount of power used by each mill is calculated. A portion of the power is charged for according to the terms of the lease at a fixed rental. The balance is charged for as surplus power In times of very low water, the power is restricted to the amount guaranteed in the lease.

Relative Cost of Water and Steam Power in the United States.—In some cases local conditions are so favourable that water power can be developed at an almost nominal cost. In other cases unforeseen contingencies have led to expenditures which have made the cost of water power excessive; greater, in fact, than that of steam power. Mr. Swain puts the average cost of steam power in the States, in favourable localities, at £4 per horse power per annum, and that of water power at about £2 per horse power per annum. Both these estimates are so low that it may be suspected that they are based rather on the nominal power of the plants than on the average actual horse power used throughout the year. The cost of water power, however, varies greatly Mr Swain states that while in the North West of the United States the cost for interest, depreciation, and water rental is about £2 2 to £2 5 per horse-power per annum, in New Jersey it is from £12 to £15 That

* "Statistics of Water Power Employed in Manufacturing in the United States." By G. F Swain Publications of the Americal Statistical Association, March, 1888.

† J. B. Francis, *Trans. Am. Soc. of C.E.*, vol. x., p. 189.

* "On the Work done for the Preservation of the Holyoke Dam in 1885," by Clemens Herschel, *Trans. Am. Soc. Civil Engineers*, vol. xv., p. 543.

water power is used at all at a cost so large as this proves that it has advantages of convenience compared with steam power which balance some excess of cost.

It is somewhat difficult to arrive at a precise knowledge of the cost of water power in the great works in America, because of the gradual way in which they have been developed, and the want of complete data as to the amount expended. Mr. C. E. Emery,* who is probably rather prepossessed in favour of steam power, has made the following estimate of the cost of water power at Lawrence. He puts the total cost of the structural works at Lawrence at £200,000, and the power utilised as equivalent to 13,000 h.p. for 10 hours daily throughout the year. That makes the cost of structural works £15·4 per horse power. The cost incurred by the mill owners in erecting turbines, sluices, etc., he puts at £9 per horse power of the turbines, or £13 per average horse power actually utilised, the turbines being generally constructed to yield surplus power in times of emergency. This makes the total expenditure £28·4 per average horse power utilised 10 hours daily throughout the year. He allows $2\frac{1}{2}$ per cent. for depreciation, $1\frac{1}{4}$ per cent. for repairs, $1\frac{1}{4}$ per cent. for taxes, 10 per cent. for interest, and 2 per cent. for working expenses, or, altogether, 17 per cent. on the capital expenditure. This makes the annual cost of a horse power at Lawrence £4·7 per annum, which he takes to be about the same cost as that of steam power with economical engines, and coal at 8s. to 12s. a ton. No doubt, however, in many cases water power can be utilised at a less cost per horse power than that incurred at Lawrence.

Cost of Water Power at Geneva.—It appears that at Geneva, for the first groups of turbines erected, of 840 h.p., and for the river works then completed, the capital cost amounted to £60 per effective horse power. The groups of turbines subsequently erected have cost only £19 per horse power. The mean cost, when the present works are completed, will amount to £27 per effective horse power. In this case the water costs nothing. If we allow 5 per cent. for depreciation, repairs, and working expenses, and 10 per cent. for interest on capital, the cost per horse power per annum will only amount to £4. In the new works below Geneva where 12,000 h.p. are to be utilised, it is estimated that the whole cost for turbines and structural works will amount to £60 per horse power for the first 2,400 h.p. When the whole installation is completed the capital cost will be only £27 per horse power.

STORAGE OF WATER POWER.

The need of storing power derived from waterfalls arises out of different considerations from those which apply in the case of steam power. A river flows day and night with an energy which varies according to the season but not from hour to hour. The work to be done necessarily varies in almost all cases and in most cases there is no demand for work to be done during half the 24 hours. If no means of storage is found a large part of the natural supply of energy flows away and is wasted. But there is another reason. In the case of water power nearly the whole cost of the power is due to interest and depreciation on the permanent works, machinery, and structures, nearly nothing is due to daily working expenses. With steam power only about one third or half the cost is due to permanent charges, and two thirds to half arises out of wages and fuel. If the engine stops for 12 hours out of the 24, coal and wages are saved, and though the cost per horse power is greater, it is only moderately increased. But if water power machinery stops for 12 hours out of the 24, there is no sensible diminution of working expenses, and the cost per horse power is doubled. At some of the American water power stations, an inducement is held out to consumers to work day and night by charging a lower rate for power at night. In other cases the difficulty is met by storing the night water to be used by day, so that the amount of power which can be supplied during working hours is doubled. It will appear in the course of these lectures, that one of the most characteristic advantages of water power, as compared with steam power, is that the former permits the storage of energy by means not costly or difficult. It is the facility of storing energy by raising water to elevated reservoirs which, in some cases, makes it profitable to pump water to be used afterwards for power purposes.

There are two distinct methods of storing energy in hydraulic systems—accumulation storage and reservoir storage. Perhaps, on superficial consideration, it would hardly have appeared likely that it could be profitable to pump water to be used for power purposes. There are cases where it is so—one of these is the system of hydraulic transmission originated by Lord Armstrong. The system of hydraulic transmission is used, and can only be used advantageously to work a great number of intermittently working machines. A single engine, working almost continuously, pumps water which actuates a great number of intermittently working motors. Naturally, the fluctuation of demand for power varies a great deal, and storage is almost essentially necessary. Perhaps it is to the invention of the accumulator—a means of storing the energy of pressure water—that the success of the system of hydraulic transmission is chiefly due. The hydraulic accumulator is simply a vertical cylinder with a heavily loaded plunger, into which the water is pumped till it is required, and from which it is discharged by the descent of the plunger. Let A be the area of the plunger in square feet, P the total load on it in pounds. Then $p = P/A$ is the pressure at which the water is delivered in pounds per square foot. If h is the length of stroke of the accumulator plunger, then $A\,h$ is the greatest quantity of pressure water it will store, and $p\,A\,h$ foot-pounds is the energy stored when it is fully charged. The pressure used in systems of hydraulic transmission is generally 750lb. per square inch. Now, one of the very large accumulators of the London Hydraulic Power Company has the following dimensions: diameter of plunger, 20in.; stroke, 23ft. At 750lb. per square inch, this accumulator, large as it is, stores only 2·4 horse-power hours—a comparatively insignificant quantity. The cost of this accumulator, reckoned on the capacity for storing energy, must be very large indeed. What makes the accumulator so important is that its rate of discharge is very great. It would probably supply 100 h.p. for $1\frac{1}{2}$ minutes. Hence, like the flywheel, the use of the accumulator is limited by its costliness to meeting fluctuations of demand in short periods of time. It cannot be used to average the variations of demand through the 24 hours. It is superior to the secondary battery in that the rate of supply of stored energy is not limited.

If a suitable site can be found, reservoirs can be built of very, very large capacity at a cost not large per cubic unit stored. Let A be the mean area of the reservoir, h the variation of depth in the reservoir, and H the height of the reservoir above the hydraulic motors driven by the water (foot units). Then the volume in the reservoir when full is $A\,h$, and the gross energy stored is—$G\,A\,h\,(H - \frac{1}{2}h)$ or $G\,A\,h\,H$ nearly. At Zurich, for instance, the storage reservoir contains 353,000 cubic feet at an elevation of 475ft. above the motors. It therefore stores 5,284 horse power hours. At both Geneva and Zurich very remarkable and extensive systems for utilising and distributing water power have been for some time in successful operation, and to these attention will be directed more than once in these lectures. In both cases the water flowing out of a large lake with a comparatively small fall, is utilised to carry a very considerable and valuable power. In both cases it has been found convenient and economical to use the low pressure turbines to pump water to a reservoir at a great elevation and to use the pumped water for ordinary motor purposes. Data may be taken from the Geneva installation, though the works in both cases are similar, and both have been financially successful. At Geneva, the Rhone flowing out of Lake Leman has by skilful arrangements been made to afford a clear fall varying from $5\frac{1}{2}$ft. to 12ft. At Geneva there have been erected on this fall or shortly will be erected, 18 low pressure turbines, giving an aggregate power of over 4,000 h.p. These turbines are used primarily in pumping a supply of water for Geneva; but since 1871 there has grown up a system of using water from the town mains for motor purposes in Geneva, and it is an important secondary function of the low pressure turbines to pump this water used for motor purposes. To begin with, it may be pointed out that low-pressure turbines, together with the building and permanent works required to create the fall, are very costly. It is desirable that to reduce the permanent charges on the energy furnished, they should work as long hours as possible. Further, the total power furnished is even now insufficient for the work to be done, and it is necessary that water power should not flow to waste; but, even for other reasons, it became necessary to use storage of energy before the present exigencies arose. In the earlier period of the enterprise to maintain constant pressure, in spite of the fluctuation of demand on the mains, it was necessary that the turbines should be constantly pumping in excess of the demand. The surplus was discharged through a relief valve, and involved a constant waste. To meet fluctuations of pressure, four large air vessels were constructed, 5ft. in diameter and 39ft. high. With these the working was smooth and successful but necessarily wasteful. When the electric installation was erected at Geneva, and driven by turbines actuated by the pumped water, the necessity of storage became more evident. At four kilometres from Geneva a site was found at an elevation of 390ft. above the lake where a reservoir could be constructed. The reservoir contains 453,000 cubic feet, and stores, therefore, 5,573 gross horse power hours of energy. Allowing for the loss at the motors driven by the water, the effective energy stored may be taken at 4,180 horse power hours. The reservoir is a covered reservoir of expensive construction. But its cost does not exceed £2·4 per horse power hour of energy stored. It is a work requiring little maintenance, and it hardly adds 3s. per annum to the cost of a horse power supplied. On the other hand, the energy stored would, without it, have gone to waste, and for this a rental is obtained of £8 per annum.

There is now in London an admirable system of hydraulic power distribution perfectly adapted to the special purposes to which it is applied, and mechanically and financially successful. But it is a system of limited applicability. Large as it is, the number of renters of power is under 2,000, and the maximum pumping capacity of the stations at present erected is 1,500 effective horse power. In the comparatively small town of Geneva, with one-eightieth of the population of London, there is a system of power distribution as large and of more varied usefulness than the system in London. There were there, three years ago, 137 motors, aggregating 280 effective horse power on the low pressure mains, and 79 motors aggregating 1,284 h.p. on the high pressure mains. The use of the hydraulic power was increasing at the rate of nearly 200 h.p. per annum. Lastly, the power in Geneva is distributed to ordinary consumers at one-fifth and for electric lighting at one-twelfth the London price.

Perhaps it is fair to add that in London there are 2,500 gas-engines, which represent a considerable aggregate power, virtually supplied from a central station. Nevertheless motive power is more generally, and more cheaply, distributed in Geneva than in London. No doubt local conditions have favoured the adoption of plans for distributing power in Geneva; but, perhaps, it has not yet been fully recognised in London what an advantage cheaply distributed power is. Perhaps, when this is better recognised, means may be found to make motive power more available as a purchasable commodity.

* "The Cost of Steam Power," by C. E. Emery, *Trans.* Am. Soc. of Electrical Engineers, March, 1893.

MANCHESTER.

The following are the regulations for wiring and fittings in connection with the supply of electric current.

The Corporation will not supply or fix any internal fittings beyond the meter on consumer's premises.

It will be necessary that the wiring on consumer's premises shall conform to certain conditions and tests both for the protection of the Corporation and also for the protection of the consumer himself. The following provisions, however, are intended for the protection of the Corporation, although they are incidentally beneficial to the particular consumers, but the Corporation will take no responsibility in respect of testing a consumer's premises for his own protection.

1. Except by special arrangement, not more than 80 16 c.p. lamps may be supplied at 100 volts from a single pair of service terminals. When more lights are to be supplied, they must be divided between different pairs of the five wire conductors. If this rule is departed from, there is danger that the pressure of the supply will not be so uniform as it should be.

2. All conductors must be protected by cut outs, which must be competent to cut off the current if this exceeds the normal current by 50 per cent. It must be impossible for an arc to be maintained between the terminals of any cut out.

3. The switches must be so constructed that they do not heat with the full current; that it is impossible for them to remain in a position between full on and full off; and that it is impossible for an arc under any circumstances to be maintained on the switch.

4. Before taking on any consumer, his premises will be tested for insulation, and they will be tested from time to time to ascertain that the insulation has not deteriorated. The Board of Trade require that any consumer whose insulation is less than 10,000 ohms shall be cut off, and the Corporation incur responsibility by neglecting to cut off such consumer. This is not sufficient insulation except in the cases of very large consumers, and the following which is taken from the Phœnix Fire Office Rules, must be adopted:

"In any electric light installation in which the current is continuous, and has an E.M.F. of 200 volts or under, the insulation resistance over the whole installation should not be below the following:

Installation of	25 lights	...	500,000 ohms
,, ,,	50 ,,	...	250,000 ,,
,, ,,	100 ,,	...	125,000 ,,
,, ,,	500 ,,	...	25,000 ,,
,, ,,	1,000 ,,	...	12,500 ,,

"When the lights are proportionate between the above numbers, then the insulation resistance should be correspondingly proportionate.

"The insulation resistance of the separate circuits of the installation should also be taken, and should be in accordance with the above table."

In cases where the supply is at more than 200 volts, the insulation must be doubled in each case.

All wiring, electrical fittings, and appliances of every description, situate on any premises intended to be used in connection with the supply of electricity from the Corporation, must be approved by the Corporation or their authorised officer before the installation is connected with the electric conductors belonging to the Corporation.

The Corporation do not undertake any responsibility for the efficiency and proper execution of any work on consumer's premises. The inspection and insulation test is made for the purpose of the Corporation only.

No installation will be connected to the supply conductors where wires are hung in a temporary or loose manner. Wires under floors are not desirable. Staples should not be used.

The Corporation will convey their electric conductors through the outer wall of buildings to be supplied and terminate with a meter at a suitable position to be determined by the Corporation engineer; and after the connection has been made no alteration shall take place until due notice has been given, otherwise the supply is liable to be stopped.

The consumer must give not less than 48 hours' notice to the Corporation in the event of being desirous of having the meter removed, and shall in no way interfere or tamper with the meter, the Corporation being empowered to withhold the supply upon infraction of this rule.

Inspection of meters will be made periodically.

The Corporation inspector is entitled to free access at all reasonable times to take readings of the meter, and to inspect or repair any work in connection with their service.

The reading of the meter shall be taken as the quantity of current used in each quarter. Should the consumer dispute such reading, it may be officially tested, and if in any quarter the meter is found incorrect, the Corporation will add or deduct for such quarter only; and if the official test certifies the meter as correct, the consumer shall bear all expense of the testing.

The attention of the consumer is drawn to the fact that most of the fire insurance companies issue regulations as to the laying down of electric light work, and the due observance by the consumers of those regulations when the installation is first laid down will probably save subsequent annoyance and expense.

Western and Brazilian Telegraph Company.—The receipts for the week ended October 13 were £2,941.

BUSINESS NOTES.

Newport.—The telegraph system has been extended to Nantyglo.

Hastings.—The new offices of the Board of Guardians are to be electrically lighted.

Southport.—The Town Council propose to acquire the tramway system in the borough.

Oldham.—The directors of the Yew Spinning Mill have decided to light their mill by electricity.

Radcliffe.—The Local Board have appointed a committee to consider the question of electric lighting.

The Royal Exchange.—Messrs. J. G. Statter and Co. are carrying out the electric lighting of the Royal Exchange.

Steamer Lighting.—The new ferry steamer for the London County Council, the "Hutton," is lighted by electricity.

Newport.—We believe that the specifications for the electric lighting of Newport will be out at the end of the month.

Liverpool Overhead Railway.—The traffic receipts of the railway for the week ending the 8th inst. amounted to £666.

Chalfont St. Giles.—A turbine has been laid down to drive a dynamo supplying current for lighting "Straton Chase."

New Business.—Mr. Malcolm Sutherland has started in business as a consulting electrical engineer at 377, Bath-street, Glasgow.

Ipswich.—A petition for the winding up of the Ipswich Electricity Supply Company, Limited, is to be heard on the 25th inst.

Fire.—A fire has done considerable damage at a shop attached to the Kennington New-street electric station of the City and South London Railway.

Change of Address.—The address of Messrs. Babcock and Wilcox, Limited, is now 147, Queen Victoria-street, instead of 114, Newgate-street, as formerly.

Hertford.—The General Committee of the Corporation have decided to postpone the further consideration of the proposed electric lighting scheme until next year.

Taunton.—At a meeting of the Town Council last week the bill of expenses that had been incurred in obtaining the provisional order for the electric light company was made public.

Pupil.—The electrical engineer to the Corporation of Brighton has a vacancy for an articled pupil at the borough electricity works. Applications to be sent to the electrical engineer.

Hull.—The Hull Corporation are prepared to take one improver into their electric light works, for a period of two years, at a premium of £30. Particulars are given in our advertisement columns.

St. Pancras.—The Vestry have accepted the tender of Messrs. E. Houghton and Son, of Stroud Green, N., for the addition of new buildings to the station in Euston-road. The tender amounted to £1,876.

St. James's and Pall Mall Company.—The electric current sold by this Company during the quarter ended September 29 last amounted to £4,820, as against £5,764 for the corresponding period of 1892.

Chester.—The members of the Town Council have discussed a proposal to adopt the Hop Pole Paddock as a site for an electric lighting station for the city. After considerable discussion the proposal was carried.

Vacancy.—Applications may be sent to the secretary of the Scottish House-to-House Electricity Company, Limited, 109, Hope-street, Glasgow, for the position of manager of the company's new generating station at Coatbridge.

Cleckheaton.—The clerk to the Local Board has reported that the Local Government Board has sanctioned the borrowing of a further sum of £1,750 for the completion of the public offices, together with £670 for the electric lighting.

Paignton.—The Local Board have received further offers from firms for providing electric lighting, and Messrs. Parnell, Bailey, Rabbich, Drew, and Bridgman have been appointed a special committee to consider the whole subject and report.

Aberdeen.—The School Board intend to apply to the Town Council for an extension of the electric light main along King-street as far as the Board's house, and in that case to obtain estimates for an installation of the electric light in the Board's office.

Dewsbury.—The Board of Guardians have resolved to give the Electric Lighting Committee power to consult an electrical engineer in respect to the scheme proposed for lighting the new infirmary and the workhouse. The expense proposed to be entailed is about £2,100.

Telephony between Barry and Cardiff.—A subsidiary line is in course of construction, and will be completed shortly between Cardiff and Barry, in order to provide facilities to cope with the rapidly increasing volume of telephonic business at the post office at Barry Dock.

St. Olave's.—The Board of Works have given the contract for the electric lighting of the new offices referred to in our last issue to Mr. W. Mackie, of Turnmill-street. He is also installing the electric light in the new St. Olave's Grammar School which is being erected in Tooley-street.

City and South London Railway Company.—The receipts for the week ending October 15 were £849, against £902 for the same period last year, or a decrease of £53. The total receipts for the second half year of 1893 show an increase of £356 over those for the corresponding period of 1892.

Personal.—Mr. R. Wynne, of Newcastle-upon-Tyne, has been appointed resident electrical engineer to the Corporation of Bury. The appointment has been made of Mr J. E. Edgcome as resident engineer and manager at the generating station at Kingston, at a salary of £156 per annum.

Abercarn.—At the ordinary monthly meeting of the Abercarn Local Board a letter was read from the Blaenavon Chamber of Trade asking the Board's co-operation in establishing telephonic communication between the Eastern and Western Valleys. It was decided to ask for particulars as to cost.

Barnet.—The chairman of the Barnet Local Board has received from the manager to the Electric Installation Company, Limited, a letter asking for an opportunity to meet the Board to discuss a scheme for taking over the lighting of the town. The Board have decided to hear what the company have to propose.

Telephony.—The National Telephone Company have made arrangements whereby their exchanges at Plymouth, Exeter, Torquay, and Paignton will be continuously open day and night (including Sundays and holidays), and the trunk wires between those places will also be always available for communication.

West India and Panama Telegraph Company.—The receipts for the two weeks ended October 15 were £373 less than for the corresponding period. For the six months ended June 30 last the directors recommend the full dividend on the preference shares and 1s. per share on the ordinary shares, after having placed £3,000 to reserve.

Ramsden, Camm, and Co., Limited.—This Company has been registered with a capital of £50,000 to take over the businesses carried on at Leopold Works and Robin Hood Works, Brighouse, under the styles of "Ramsden, Camm, and Co." and "S. H. Byrne," and to carry on the business of wire drawers, manufacturers and galvanisers, etc.

Electro-Tanning.—Mr. L. A. Groth has removed from his London address, 3, Tokenhouse buildings, E.C., to Orbe, near Lausanne, Switzerland, where he has taken the technical management of the largest tannery there which is now being enlarged and reconstructed entirely according to "Groth's system" of tanning by aid of electricity.

Falmouth.—The chairman of the Lighting Committee of the Urban Sanitary Authority has reported that he has, in compliance with the resolution passed at the last meeting, requested Messrs. Veale and Co., electrical engineers, St. Austell, to prepare a report on the electric lighting of Falmouth main streets, and that he has received the report. The report is to be considered by the entire Authority.

Shoreditch.—A Mr. W. T. Baker has forwarded to the Shoreditch Vestry plans and copy of a new scheme for the erection of baths, electric lighting station, and dust destructor. He claims that there was every possibility that his scheme would recoup itself out of its own earnings. The plans have been sent to the Electric Lighting Committee and the Baths and Washhouses Commissioners.

Islington.—Mr. Gay, the electrical engineer to the Vestry, is now busily engaged in viewing the various sites under the consideration of the committee, assisting in the negotiations for those sites, and considering the question of distribution, with a view to the preparation of a scheme for distributing the light. He will then prepare specifications for mains, plant, and works, and get out estimates for loans.

Dover.—The electric light has now been introduced into the mills of Messrs. Chitty, of the Charlton Flour Mills. The premises are fitted with 126 incandescent lights of 16 c.p., whilst the outside court and entrance yard are illuminated by two of 60 c.p. The current is obtained from a dynamo on the premises, driven by the ordinary mill machinery. The installation has been carried out by Messrs. Christy Bros., of Chelmsford.

Rugby.—Rugby School and the boarding houses connected with it are now lighted by electricity. A dynamo, capable of generating current for 1,000 lamps, has been supplied by the Brush Company, and it is run by a Dowson gas engine of 40 h.p. nominal. As accumulators have not been provided, a smaller engine and dynamo have also been put in to run when the load is light. A local telephone system is suggested to be provided.

The Fowler-Waring Cables Company, Limited.—This Company is now represented by Mr. Alfred E. Garbutt in the North of England; by Mr. J. Vincent Swindells in Manchester and Midlands district; and by Mr. Charles Parker in the Eastern and South Eastern districts, including London. Offices will shortly be opened in Newcastle as the centre of the Northern district, and in Manchester as that of the Manchester and Midlands district.

Temporary Electric Lighting.—Messrs. Vaughan and Brown, of 15, 16, and 17, Kirby street, London, E.C., have made arrangements for lighting by electricity the Agricultural Hall during the holding of the three exhibitions—namely, the Brewers', the Confectioners', and Stanley Shows. The hall will be illuminated with 50 arc lamps, the current to be generated by a Brush dynamo driven by a 20 h.p. Stockport gas engine lent by Messrs. Bilbie, Hobson, and Co.

Buxton.—A letter was read at a meeting of the Local Board last week from Mr. C. E. Baker, Local Board's Association, asking if the Board contemplated any parliamentary proceedings next session on the subject of electric light. Mr. Hulme asked what had become of the Electric Light Committee that was appointed a long time ago. Mr. Lawson said it had "gone out." Mr. T. Cooper said the committee referred to had power to spend £20, and Mr. Lawson observed that they ought to be surcharged if they did so.

Cardiff.—The capstone of the chimney stack erected to serve the Cardiff electric lighting station at Canton Common was laid on Tuesday by the Mayor (Councillor W. E. Vaughan). The stack is 150ft. in height, and has a diameter of 13ft. at the top and 26ft. at the base. It is built of Ebbw Vale bricks, with facings of buff and red pressed bricks. No fewer than 240,000 bricks and no less than 80 tons of mortar have been utilised in the construction of the chimney.

Rochester.—A notice from the Chatham Electric Lighting Company as to opening pavements to connect Mr. Bomrose as a customer, was considered at a meeting of the Town Council last week. It was resolved that the pavements must be put into proper condition after the execution of the works, and that the town clerk call attention to the fact that the amounts due from the company to the Corporation are still in arrear, and that they must be paid at once.

Bolton.—The Gas and Lighting Committee of the Bolton Corporation invite tenders, as will be seen from our advertisement columns, for the supply and erection of switchboards, accumulators, connections, etc. Specifications, plans, and forms of tender may be obtained on application to Mr. J. H. Rider, M.I.E.E., borough electrical engineer, Town Hall, Bolton. Tenders, endorsed "Switchboards," must be addressed to Mr. Alderman Miles, chairman of the above committee, at the Gas Offices, Bolton, not later than November 18.

Lancaster.—The Electric Lighting Committee of the borough of Lancaster invite tenders for the brickwork, boiler seats, etc., required in the fixing of two Lancashire boilers and one set of Green's economisers at the electricity works, Morton street yard. Plans and specifications may be seen, and bills of quantities and forms of tender obtained on application at the office of Mr. John Cook, A.M.I.C.E., borough surveyor, Town Hall, Lancaster. Sealed tenders, endorsed "Setting Boilers," to be sent in not later than 9 a.m. on Monday, the 23rd inst.

Navigation and Electric Launches.—At Kingston on Thames, Mr. John Hill, of the General Electric Power and Traction Company, Limited, Platt's Eyot, Hampton, was summoned for having, on July 15, navigated the electric launch "Fasshild," off Platt's Eyot, on the Thames, on the occasion of Molesey Amateur Regatta, so as to obstruct and impede and interfere with a certain pair-oared race, contrary to the by-laws of the Thames Conservancy. The magistrates having heard the evidence, fined the defendant 5s., and ordered him to pay costs amounting to £2 0s. 6d.

Bournemouth.—The town clerk reported at a meeting last week that the Board of Trade had consented to entertain the application of the Council for a license, and that the formal application and deposits had been made, and the license might be expected to be issued in from three to four months time. At the same meeting the surveyor presented to the Parks Committee a report estimating the cost of illuminating the proposed fountains in the gardens by electricity at £204 9s. each. The scheme was referred back to the committee. Application is to be made to the Local Government Board for sanction to borrow £250 to defray the cost of providing means of communication between the members of the fire brigade and the fire station.

Leamington.—The Telephone Sub-Committee reported at a meeting last week that they had considered the question of providing telephonic communication between the various Corporation offices in the borough, and had had an interview with the manager of the National Telephone Company, who attended their meeting, and stated that the Corporation were entirely clear of his company, inasmuch as no agreement had been entered into, but that he was prepared to reopen the question if desired. The sub-committee have instructed the town clerk to ascertain the cost for the Council to have the telephone plant, etc., in their own hands, so that it shall belong exclusively to the Corporation. The Council have agreed to this.

Southend.—The minutes of the Highways Committee of the Town Council of the 14th ult. contained a note to the effect that the town clerk be instructed to reply to a letter from Messrs. Crompton and Co., enquiring whether the Corporation would consider a proposal for lighting some of the principal streets with arc lamps from the existing electric plant at the pier. The Town Council have empowered the Highways Committee to invite, by advertisement, offers to undertake and carry out the powers vested in the Corporation under the Southend Electric Lighting Order, 1891, special regard being had to the system of lighting, the maximum charges to consumers, and the time for which any contract for the purpose or deed of transfer should run.

Tenders for Wiring.—The chairman and board of management of the Midland Deaf and Dumb Institution, Friargate, Derby, invite tenders for the wiring, provision and fixing of the electric light fittings, the alterations to existing gas fittings where required, and the accessories of the whole or any of these for the electric lighting of the institution. Copy of the specification and form of tender may be obtained on and after the 23rd inst. from Messrs. Bramwell and Harris, of 5, Great George street, Westminster, S.W., or from Mr. J. E. Stewart, the resident engineer, at the Corporation Electric Lighting Station, Silk Mill-lane, Derby. Tenders to be addressed to the chairman of the board of management, and delivered at the above institution on Monday, the 6th November. Full particulars are given in our advertising columns.

Lighting Rubber Works.—The Para rubber works of Messrs. J. E. Hopkinson and Co., at West Drayton, have been lighted by electricity by Messrs. Cathcart, Peto, and Radford. The current is generated by a dynamo driven by a small Tangye's steam engine. The dynamo is capable of supplying current to 80 or 90

16-c.p. lamps at a pressure of 100 volts. From the switchboard three lighting circuits run to feed the lights—two to the factory, and one to the offices, engineering, and packing rooms. The fittings used in the factory are of two kinds, the majority being plain pendants. The other style of fittings used is one made especially by Messrs. Cathcart, Peto, and Radford for use in mill-lighting. The number of lights in the factory offices and out-buildings is close on a hundred. Accumulators are used in conjunction with the dynamo.

Lanark.—At a meeting last week of the County Council, the clerk laid before the meeting a communication from the Caledonian Electric Supply Company, Limited, intimating that they intended to apply to the Board of Trade for a provisional order to authorise them to supply electricity for all purposes within the district and area comprised in the parish of Blantyre, and asking the consent of the County Council. It was agreed that in the absence of information and in view of the fact that when asked for it had not been given, the Council resolved to decline to grant consent. The Council appointed a committee to consider and report upon the present telephone system, and the best means of securing an efficient and economical telephonic service for the benefit of the public and for the administrative departments of the county, and of protecting the community against the disadvantages of monopoly, with power to confer with other local authorities on the subject.

Birkenhead.—Several months ago the Town Council adopted a resolution in favour of carrying out the provisions of the electric lighting order, and a sub committee was appointed to consider the best means of laying down a system of electric lighting. This committee engaged Mr. Shoolbred and Dr. Hopkinson (London) to report on the best means of lighting the town. These experts have now presented their reports, in which they state that they consider no great difficulty would be met in doing the work efficiently, but owing to the straggling character of the district the cost would be considerable, and this is variously estimated at from £15,000 to £40,000. The sub committee now think it advisable to interview Mr. Shoolbred and Dr. Hopkinson personally, but by many members of the Corporation the question is being raised as to whether it would not for the present be advisable to let the matter rest, or, on the other hand, permit a private company to undertake the work.

Weston-super-Mare.—At a committee meeting of the Town Commissioners on the 3rd inst., Mr. Hammond attended and fully explained the advantages to be derived from electricity for lighting the town and other purposes. The committee adjourned the subject for further consideration. A letter was read at a meeting of the Commissioners last week from Messrs. Herbert and Small, electrical engineers, of Bristol, giving gratuitous information in case the Board should decide to hand over their right to a private company. Mr. Phillips thought the question of electrical lighting for the town should be seriously taken in hand. He would propose that a special meeting of the whole Board be held at an early date in order that financial matters in connection with the proposed scheme might be discussed. Mr. Pethick thought it was the duty of the sub-committee to examine and report as to the financial question. He thought it would be much better for such a course to be adopted than to refer the matter to the whole Board. The Chairman pointed out that most of the members were on the Finance Committee. Mr. Phillips then withdrew his proposition, and it was accordingly decided that the matter should be considered at an early date by the committee.

Plymouth.—The Works Committee of the Town Council recommended last week that application be made and all necessary proceedings taken in the next session of Parliament to obtain powers authorising the Corporation to supply electricity within the borough of Plymouth. Mr. Jinkins having moved the adoption of the report, Mr. Bazley asked for further information as to the proposal to obtain powers to supply electricity within the borough. Mr. Keswill said the Electric Lighting Bill would only cost them about £100, and it would protect them against outsiders. They might require electricity in connection with their tramways. He hoped the Council would pass the resolution so that they might be put on an equality with other and smaller towns which had obtained the same powers. Mr. Bond said they were hopeful that at some time they would be able to provide their own power for electric lighting in connection with the water supply as suggested in the report of the water engineer. The Water Committee would support them in what was suggested with regard to electric lighting. Mr. Pethick agreed that the town should be, if possible, lighted by electricity; and the sooner it was done the better. They had abundance of water to provide the electricity, or for any other purpose. The report was adopted.

Brazilian Submarine Telegraph.—The ordinary general meeting of this Company was held on Wednesday at Winchester House. Sir John Pender, who presided, remarked that the receipts for the half year had been £106,860, or a decrease of £7,032 compared with those for the previous half-year, although the diminution of their income had been only £5,010. In the half year under review they had carried about 3,500 more messages with South America than in the previous six months, although they had received £7,920 less. This was owing to a reduction in the tariff of charges from April 1 last, and to a further reduction in the exchange value of the Brazilian silver currency, the value of the milreis having averaged in the half year 12¼d. as against 13¾d. in the previous half year. The total expenditure for the six months had been £40,580, or £16,014 more. This was a large increase, but it had arisen from an exceptional state of things. In the present half year, which was now more than half expired, they had had no expenditure on repairs, and he hoped that they would be able to go on for some time without incurring any further outlay. Notwithstanding the large expenditure referred to, they were able to pay the same dividend, although they were not adding to the reserve fund to the same extent that they had hitherto done. He concluded by moving the adoption of the report, which was carried.

York.—The Streets and Buildings Committee of the Corporation have visited Scarborough, at the invitation of the Hon. C. A. Parsons, for the purpose of inspecting the installation of the electric light by Messrs. Parsons and Co., of Newcastle, for the Scarborough Electric Supply Company. The system adopted at Scarborough is one of the six which have been selected out of a number of others by the York Corporation. The members of the committee were met by the Hon. Chas. Parsons, Mr. A. A. C. Swinton (managing director), and Mr. G. S. Peck (resident engineer). The deputation was first shown a transformer sub station, a number of which are placed at convenient intervals throughout the town. The committee also viewed one of the junction boxes, which are placed at distances of about 50 to 70 yards apart. They were then driven to the station on the Seamer road. The plant here is so arranged as to be interchangeable, the two steam turbine alternators being capable of running jointly 10,000 8-c.p. incandescent lamps. The committee then proceeded through the town and inspected the various shops where the company have made installations of the electric light. At night the deputation and several directors of the local company, including the Mayor (Mr. John Dale), Mr. G. L. Beeforth, Mr. G. Alderson Smith, and Mr. J. Hall, were entertained to dinner by the Hon. C. A. Parsons at the Grand Hotel, the ex mayor (Lieut. Colonel Steble) presiding.

Bristol.—Mr. C. Wills presided over the proceedings of the Electrical Committee of the Town Council on Friday of last week. Over 40 applications were received for the appointment of assistant engineer, and Mr. Hanson, now engaged in electrical works at Newcastle on Tyne, was selected for the post. Several applications for light at short distances beyond the area were considered and it was agreed to supply the Cathedral, St. John's Church (City), and Broadmead Baptist Chapel, on the applicants giving the usual guarantee. Some delay has arisen over the street-lighting, on account of the lamps not being ready. Some discussion took place with reference to questions that were asked at the last meeting of the Council, and the engineer (Mr. Kapp) explained that it was customary and prudent to lay down only sufficient plant for the area determined upon, and then, if extensions were resolved on, to provide further machinery, etc. The committee talked for a considerable time about allowing engineering pupils or improvers to be taken at the works. A majority of the committee were against the engineer taking improvers at premiums as a sort of perquisite. A resolution was proposed that the engineer should be allowed to take improvers, but it was rejected by five votes to three. Mr. Pearson gave notice of his intention to move that improvers should be taken without premium for two years, the Corporation getting the benefit of their services in return for the experience offered.

Windsor.—At a meeting of the Town Council, Councillor Dyson had given notice of motion "That this Council request the Board of Trade to revoke the provisional order granted to the Windsor and District Electric Lighting Company; that the Council do apply to the Board of Trade for a provisional order for Windsor and Eton; and that a committee be formed, to be called the Electric Lighting Committee, to consider the whole question and to report from time to time to the Council on the subject." Arising when the time for the matter to be brought forward arrived, Councillor Dyson said at a meeting last week that since he gave notice certain questions had sprung up which seemed to alter the phase of the whole thing, and though he did not at all desire to do anything or say anything but what would lead the Council to suppose that he believed that for the order to be revoked would be the best proceeding, owing to what had arisen since he gave notice, he felt he should only be doing his duty to those gentlemen who were interested in the late company when he asked permission for the motion to stand over. If anything had been done by the Council it would have to be done before November; but he did not wish in any way to force the gentlemen who were grappling with the late company. The clerk asked whether Councillor Dyson would withdraw altogether, or only till the next meeting of the Council. Councillor Dyson said he would give notice if he intended to bring the motion forward again.

Halifax.—The scheme of the Town Council for expending £30,000 on electric lighting has been approved by the Board of Trade. Since the application was made, the Halifax Mutual Electric Light and Power Company, who have met the requirements of the town for several years, have announced that they will discontinue the supply of light on November 18 next. At a meeting last week of the consumers of the light, presided over by Mr. Needham, president of the Halifax Drapers' and Hosiers' Association, several speakers stated that serious inconvenience would be caused by the withdrawal of the light, especially at this period of the year. Subsequently a deputation waited on the Electric Light Committee of the Corporation, and urged them to arrange with the company for the light to be continued until the Corporation were in a position to supply it themselves. The committee stated that as yet they had been unable to make any arrangement for the temporary supply of the light, but promised further consideration of the matter. The committee have fixed upon a site for the electric station in Multure Hall road, a vacant plot of land owned by the Great Northern and Lancashire and Yorkshire Railway Companies. Negotiations are pending for the acquisition of the site, and as soon as these are completed building operations will be commenced. A letter has been sent to the Halifax Corporation by Mr. T. England, solicitor, on behalf of

the Halifax Mutual Electric Light and Power Company, stating that the company would, in consideration of the Corporation paying them £2,000, guarantee to continue the light for 12 months; or, as an alternative offer, that the company would accept £4,000 for the plant, the Corporation taking over the same at once. A sub-committee appointed by the Gasworks Committee to consider the offers has recommended that neither be accepted. The offer of Mr. W. H. D. Horsfall, architect, to prepare plans, etc., for the proposed electric light works has been accepted.

Fleetwood. The Highway, Lighting, Fire Brigade, and Building Committee recommended, on the 22nd ult., that the proposed electric lighting station should be erected in the town's yard, London-street, subject to the plans and details being afterwards agreed upon; that the present street lamps be used as far as possible for electric lighting, and that the requisite alterations to the lamps be included in any scheme which may be submitted to the Board; that in the opinion of this committee the low-tension system, with accumulators, should form part of any electric lighting scheme for this district, and that the motive power for working the scheme should be obtained by means of producer gas, working suitable gas-engines; that the correspondence now produced and read from Mr. J. A. McMullen be received, and that Mr. McMullen be invited to meet this committee on an early date, on terms now named, for consultation upon the question of electric lighting in this district. The Clerk of the Improvement Commissioners read a letter at a meeting last week from the Board of Trade saying that they had deferred the consideration of the question of the revocation of the order for a further period of six months. Mr. Hudson, of the Electric Lighting Committee, reported concerning the position of the electric light question. No doubt the public were anxious the work should be pushed on, but the installation of the electric light, costing as it would do several thousand pounds, must not be undertaken until it was proved they had a scheme that would be a benefit to the town and a source of revenue. The committee had now formed an idea of what was wanted for Fleetwood. The chairman said it would be satisfactory to the Board to know the public were working hard. In reply to Mr. Shuttleworth, Mr. Hudson said the engineer was favourable to gas as a motive power. It was understood that a meeting of ratepayers would be held before deciding on the question. Mr. Crosby said he should have moved there be a public meeting.

Glasgow. Some eight months have passed since Lord Provost Bell formally opened the central electric station and switched on the street lamps, and already it has been found necessary to make a new departure in regard to the method of supply. The station which the Corporation erected in Waterloo-street to meet the wants of the central area of the city was equipped at the outset with machinery which it was thought would suffice for several years at least. It consisted of seven of Willans's central valve compound engines—two of 80 h.p., two of 150 h.p., and three of 250 h.p.—and an equal number of dynamos, two having an output of 400 amperes at 120 volts, two an output of 400 amperes at 230 volts, and three an output of 670 amperes at 230 volts. The applications for light for private premises have been so numerous that at present two new engines of about 350 i.h.p. each are being put down to light an equivalent of 1,400 8-c.p. incandescent lamps. Beyond this plant, the station contains four dynamos for the arc lamps with which the streets are illuminated. The station was originally designed to supply 22,000 incandescent lamps. The new machinery, however, will increase the number to no fewer than 40,000. Beginning with 60 customers, the officials have had continuous demands made on them, until at present the applications have reached the large number of 268. They have come from all classes of consumers—from wholesale warehousemen, retail shopkeepers, photographers, banks, public institutions, and from the post office, while the Corporation themselves take a very large supply; and as showing the general satisfaction which is experienced, it may be stated that in no instance has a customer wished to have the light withdrawn. Among the customers are many small consumers occupying offices. The current is used for the most part for lighting purposes, but in several cases it is being employed to drive motors and ventilating fans. The municipal buildings take the largest supply yet sent out, the lamps there being equivalent to 1,500 of 8 c.p. In the post office there are 1,000. The Theatre Royal has 1,160, the Clydesdale Bank 900, the Union Bank 744, the Central Agency, Bothwell-street, 700, the Young Men's Christian Association 540, the Windsor Hotel 390, and the Grand Hotel 294. To the Polytechnic warehouse in Argyll-street a supply is sent equivalent to 570 lamps. Messrs. Daly and Co., warehousemen, Trongate, have a supply equal to 520 lamps; and Lafayette, the photographer, a supply equal to 400 lamps. As matters are at present, the station cannot give any more light to private consumers, and in the meantime it has been decided not to consider any new applications. The station, in fact, has reached the limit of its load. As to the policy which the committee may ultimately adopt, nothing has yet been definitely decided. At present a sum of £3,000 is being expended in laying down three feeder mains for private supply. These consist of copper strip, of which no less than 94 tons is now laid below the pavements. Workmen are now engaged in rearranging the machinery in the station. To make room for the two new engines which are being brought in, two of Easton and Anderson's compound marine type of engine, each of 100 h.p., which were put down to drive the dynamos for the arc lighting of the streets, are being disposed of, and the dynamos are being taken to the premises in John-street which the Corporation acquired from Messrs. Muir, Mavor, and Coulson, Limited, when they resolved to undertake the supply of electric light. Shortly after the opening of the Waterloo-street station these premises were closed. Fortunately they were not dismantled, for it is now intended to generate there all the electricity required for the lighting of the streets. The old machinery, consisting as it does of two tandem compound engines, each of 200 h.p., is quite sufficient for the purpose, as will be readily understood when it is mentioned that at present there are only 78 arc lamps in operation. While it is the case that all the available space in the Waterloo-street station is being gradually utilised, some time will elapse before it is fully occupied, there yet being room for four other engines of the size of those now being placed in position. With the approaching completion of the operations of the Central Railway Company, the work of lighting Argyll-street is being proceeded with. The necessary conductors have been laid from Bishop-street, Anderston, to the Cross, and the lamps will shortly be erected, with the exception of a few between Union-street and Queen-street, where the construction of the railway is still proceeding. The amount of money expended up to this point on electric lighting is about £100,000. The price of current to consumers per Board of Trade unit is 7d.

The Leeds Tramways.—The Highways Committee of the Leeds Corporation have inspected the South Staffordshire electrical overhead tramway system. The visit was an important stage in the enquiry at present being made by the committee for the purpose of arriving at a determination as to the future system of tramway traction which shall be adopted in Leeds. One of the features of the South Staffordshire system which has attracted towards it the attention of the Leeds Tramways Committee is that the objection of the overhead wires is here modified by the adoption of only one line of posts, instead of two, as in the case of the Thomson-Houston system on Roundhay-road. The deputation, which consisted of nearly all the members of the Highways Committee, left Leeds by a special train on Friday, and arrived in Birmingham about seven o'clock, and went to the Grand Hotel, where they stayed the night. After dinner, the evening was spent in a long discussion. The committee was supplied with a compendious statement—prepared by the clerk (Mr. John Harrison)—on the observations of the system they had come to inspect, made during a previous visit by a smaller deputation, consisting of four members. The town clerk's notes on the system contain the following remarks: The system was selected after carefully inspecting and considering that of the Thomson-Houston Company. The cars do not run so steadily as those in Leeds, the principal reason for which is, it is suggested, that the vehicles are four-wheeled, and were built originally for steam power. The lines were also originally laid for steam cars by the South Staffordshire Company, and not by the local authority. The cost of laying the lines, it is further stated, was put down at £7,000 per mile. The Roundhay-road line cost £4,372 per mile. At Walsall the original promoter got £20,000 for his concession. This is stated to be about 4d. per car mile, as against 8d. per car mile for steam. If the cost of working were the same as steam (whereas it is only half), electricity would be much more profitable, being more popular, and, therefore, more largely used. The stationmaster at Birmingham confirms this statement, averring that since the electric tram lines have been down they have had a greatly increased railway traffic. The posts are about 60 yards apart, and may be and are intended to be utilised for lamps, either gas or electric. In that case a double set of machinery will be necessary—all duplicated, in fact, except labour—beginning with the dynamos. Exchange engines will become necessary—that is, such as may be used for either traction or lighting. The tramways company use the earth return, and say they have no difficulties. If they existed, however, they might be met by the telephones having metallic returns. The men employed by the tramways company average about 11 hours a day and six days a week. Cars run from 7 a.m. to 11 p.m. It has been suggested that this system cannot be applied to Leeds because of the greater width of the streets; also that it has not had a fair winter's trial at Darlaston and Walsall, having only been working since last January; and, further, that it is a dangerous system, and that frequent accidents happen in connection with it. Upon those points it was for the committee on Saturday to satisfy themselves. Appended to the notes is an account of interviews he had with Mr. Sellon and Mr. Hammond. Mr. Sellon is strongly in favour of the conduit system, by which the wires are underground instead of overhead. He assured the town clerk that the conduit system will succeed against all others. This system is now at work at Budapest, and is about to be put down in Madras. He also stated that he was himself aware that an improved and perfect conduit system now exists. There are several objections to the conduit system, says the town clerk, which may not, however, be insuperable: 1. In regard to cost. The conduits will cost £2,000 per mile more than the overhead system. It might be possible, however, in Leeds to have a portion of the system conduit and the remaining part overhead, as it would be quite practicable for one dynamo to work both conduit and overhead systems. In this case some three miles of the centre of the city might be worked on the conduit system and the outer parts on the overhead principle. It was for the committee to consider whether an outlay of £6,000 would not be justified for the purpose of having the conduit system instead of the overhead system in operation in the heart of the city. 2. The width of the conduit, or slot, is another objection. This in Budapest is 1½in., being of sufficient width to admit of the perfect insulation of two wires. Under the new clause, as settled by the Joint Committee of Parliament, Mr. Sellon states that one wire only will be necessary, inasmuch as the telephones must use the metallic return instead of the tramways, and he affirms that in this case the width of the slot could be reduced to that of the cable system at Birmingham. 3. Another difficulty in connection with the conduit system is the disconnec-

tions at the points and crossings, which in Budapest have given great trouble and annoyance. Mr. Sellon states, however, that this difficulty may be and has, in fact, been overcome. The town clerk remembers that whilst the telephone v. tramway case was being heard before the Joint Committee it was also mentioned, as another objection to the conduit system, that rain or snow caused disconnections. This subject, however, was not discussed by him with Mr. Sellon. Mr. Hammond informed the town clerk that he had now given up contracting, and devotes himself entirely to advising corporations and public bodies on electrical matters. He would be glad to advise to advise the Corporation of Leeds if the services of an electrical expert should be required. On Saturday morning the committee went to Darlaston, where they were met by Mr. Alfred Dickinson, manager of the South Staffordshire Company, under whose guidance they went in a special car to the generating station. One favourable circumstance that was reported to the committee was that there had been no accidents, and that there had been far fewer complaints than in the case of steam tramways. The arms of the poles vary from 3ft. to 13ft., and it was stated that they could be extended to 15ft., which would be large enough for any of the streets of Leeds. In discussing the conduit system, the case of Blackpool was mentioned, but that, it was pointed out, was a mere plaything. Mr. Sellon, when pressed to instance a practical proof of the efficiency of the conduit system, cited that in operation in Budapest, and another about to be laid down in Madras. When the inspection was concluded, the party returned to Birmingham. After luncheon, at which they were joined by Mr. Dickinson and Mr. Sellon, they left the Midland capital for Leeds, arriving in the city about six o'clock. No decision or formal expression of opinion on the merits of the system they had inspected was made; but it is probable that a special meeting of the committee will be shortly held to consider the whole question.

PROVISIONAL PATENTS, 1893.

OCTOBER 9.

18880. **Improvements in automatic electric intermittent motors for driving the mechanism of recording instruments and the like.** George William Farrall, 34, Ann street, Tettenhall road, Wolverhampton.

18894. **Improvements in standards of E.M.F.** Alexander Muirhead and Joseph Arthur Lovel Dearlove, 124, Chancery lane, London. (Complete specification.)

18911. **Improvements in electrical contact apparatus worked by passage of railway trains.** Edward Tyer, 28, Southampton buildings, Chancery lane, London.

18912. **Electrical apparatus for signalling on railways.** Edward Tyer, 28, Southampton buildings, Chancery lane, London.

OCTOBER 10.

18945. **Improvements in compositions for use in telephonic transmitter circuits and in the process employed in their production.** Alfred George Brookes, 55, Chancery lane, London. (Alfred Collinson Cousens, United States.) (Complete specification.)

18951. **Improvements in electricity meters.** Joseph Edmondson, Penny Bank chambers, Halifax.

18977. **Improvements in regulating the supply of electricity to electric glow lamps.** Thomas Rudworth Sharp, County Chambers, Martineau street, Birmingham.

18986. **Improvements in and relating to electric motors.** William Taylor, 4, Dalton place, Hornsey road, Holloway, London.

18990. **Improvements in the method of and apparatus for electrically heating or working metal.** William Phillips Thompson, 6, Lord street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

19018. **Improvements in a system of electrical transmission.** Job Albert Davis and Robert Ashworth Fowden, Norfolk House, Norfolk street, London.

19024. **Improvements in trolley supports for electric railways.** Johan Martinus Andersen, 2, Lancaster place, London. (Complete specification.)

19044. **Improvements in obtaining synchronous working of two rotating electric motors.** Sydney Pitt, 24, Southampton buildings, Chancery lane, London. (Julius H. West, United States.)

OCTOBER 11.

19079. **Improvements in switches used for the proper control of electric light currents.** George John Parfitt and George John Tom Jelley Parfitt, Electric Light and Power Works, Keynsham, Somerset.

19080. **Registering rifle shots on a target automatically or by electricity.** Alfred Hagger and Samuel Brame, 42, High street, Shrewsbury.

19088. **Improvements in cables for telegraphic and telephonic purposes.** Moritz Immisch, 52, Chancery lane, London.

19094. **An improved shade for oil, gas, electric, or other lights.** James Frederick Hoyne and George Robert Stoddart, 52, Chancery lane, London.

19127. **Improvements in printing telegraph systems.** Samuel Rush Linville and Louis Frederick Hettmansperger, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

19142. **Improvements in electrical fittings.** Edwin Freund, 122, Trinity road, Upper Tooting, London.

19122. **A duplex electric arc lamp.** Charles Tyringham Praed and William Hopkin Akester, 28, Southampton buildings, Chancery lane, London.

19145. **Improvements in apparatus for the electrolytical decomposition of brine and other liquids.** Herbert Guthrie and Malcolm Guthrie, 46, Lincoln's-inn fields, London.

OCTOBER 12.

19146. **Improvements in or relating to telephone book holders or the like.** John Francis O'Brien, 6, Lord street, Liverpool.

19152. **Mercurial voltmeter.** Reginald Beavan, Harberton, Silverdale, Sydenham.

19183. **Improvements relating to the transmission of signals through submarine and like cables, and apparatus for effecting the same.** Alexander Muir, 124, Chancery lane, London.

OCTOBER 13.

19250. **An improved method and means for slaughtering or killing all kinds of cattle scientifically by electricity.** Edwin Marsh, 13, Edward street, Leeds.

19251. **An electric indicator for use in colliery-engine houses and railway-signal cabins.** Charles Brooke Crawshaw and James Battye, Rufford Lodge, Oxford road, Dewsbury.

19283. **An electric heater.** Edward Carstensen de Segundo and Walter Durham, 28, Southampton buildings, Chancery lane, London. (Complete specification.)

OCTOBER 14.

19319. **Improvements in measuring and recording instruments for electric currents.** Jean Grazier and Emile Batault, 45, Southampton buildings, Chancery lane, London.

19363. **Electrical, viz., pneumatical or mechanical apparatus for automatically indicating the names of railway stations or stopping places and to be eventually employed for advertising purposes and indicating the time.** Alexander Rogalla von Bieberstein and Ernst Frost, Grosvenor Hotel, Victoria Station, London.

SPECIFICATIONS PUBLISHED.

1889.

15230. **Electric batteries.** Vavasour. (Second edition.)

1892.

14124. **Electromotors.** Hurd. (Third edition.)

NOTES.

Aberdeen.—An electric tramway is proposed to be constructed in this town.

The Post Office.—A successor to the late Sir A. S. Blackwood has not yet been appointed.

Brighton—Rottingdean.—The construction of this electric railway will shortly be commenced.

Glasgow.—The directors are considering the method of haulage to be adopted on the Glasgow District Subway.

Long-Distance Telephony.—Telephonic communication is being established between Berlin and Elbing, a distance of 310 miles.

The Telegraph to Gilgit.—The telegraph line from Srinagar to Astor has been completed, and Gilgit is now in telegraphic communication with India.

Civil Engineers.—A recent list of the various classes of members constituting the Institution of Civil Engineers shows a gross total of 6,418, against 6,274 12 months ago.

Carriage-Warming.—An improved system of heating carriages by steam is being adopted on the trains of the Manchester, Sheffield, and Lincolnshire Railway Company.

Midland Counties Engineers.—A special general meeting of the Chesterfield and Midland Counties Institution of Engineers will be held at Chesterfield on the 4th proximo.

Bradford.—The two principal features of the Bradford Corporation accounts for the last financial year are the net loss on the gas and about an equal net gain on the electricity.

Kingston-on-Thames.—The new buildings of the Surrey County Council are lighted by electricity. The inauguration of the central station has been postponed to the 4th prox.

Book Received.—We have received from the W. J. Johnston Company, Limited, 167-176, Times-buildings, New York, a copy of Cox's "Continuous-Current Dynamos and Motors."

Cardiff.—The Public Works Committee of the Town Council have advised the latter to purchase the tramway system, so that the entire streets may be under the control of the Corporation.

"Siemens" Incandescent Lamps.—As mentioned on another page, Messrs. Siemens Bros. and Co. will, on and after November 10, sell "Siemens" incandescent lamps at 1s. 6d. each.

Southampton. — The extensive works which the South-Western Railway Company has decided to undertake in connection with the docks at Southampton will be lighted by electricity.

Theatre-Lighting.—The Paris Opera House presented a pretty spectacle the other day, on the occasion of the entertainment of the Russian naval officers, and when the house was equipped with beautiful electric floral decorations designed by M. G. Trouvé.

Lighting of the City.—The Commissioners of Sewers have decided to have a report prepared by the engineer showing what failures of the public electric lighting have occurred during the past quarter, and on what occasions gas has been used in substitution.

Milan.—An international exhibition is to be held next year in Milan. The offices are at 3, Via Ugo Foscolo, Milan. The tramway on the Thomson-Houston system, referred to in a previous issue, has now been experimentally set in operation from the Via Vincenzo Monti to the Sempione.

Electro-Harmonic Society.—Do not forget that the second smoking concert of the season will take place this (Friday) evening at the St. James's Hall Restaurant, Regent-street, W., beginning at eight o'clock. The interesting programme was given in our last issue.

The Brussels Railway.—As mentioned in a previous issue, the local authorities of Brussels are considering a scheme for promoting rapid transit between the various parts of the city. The syndicate formed to deal with the matter have secured the services of Mr. J. H. Greathead.

Chicago Exhibition Awards.—Additional awards in the department for electricity at the World's Fair have been made by the jury, including six to Germany and one each to Great Britain, Austria, and Russia. The award in the British section was taken by the Epstein Electric Accumulator Company, Limited, for storage batteries.

A Point for Municipalities.—In discussing the subject of haulage on tramways, it should be borne in mind that mechanical traction allows of a higher speed being attained—whether permitted is another matter—than with horses, that the speed with cable cars is limited, and that with electricity any rate of speed within reasonable bounds is practicable, and specially applicable for suburban routes.

Spithead.—In the presence of Major-General Geary, Captain Bale, R.E., and other military experts, the new electric appliances at Noman's Fort, one of the Spithead defences, were successfully tested last week. The powerful search-light and the light around the gun-galleries and magazine were found to act perfectly. The work of fitting the forts has been conducted by submarine sappers from Gosport.

The "Electrical Engineer" Appreciated.—As an illustration of the high appreciation and interest manifested in English electrical journals in the colonies, we may mention that the Railway Institute of New South Wales have bound and placed in the circulating branch the *Electrical Engineer* and the *Electrical Review*. Various other journals are to be sold, not being considered of sufficient value to be retained.

Morley.—The Morley Corporation invite particulars of schemes for the lighting of the Town Hall and the borough generally. A premium of £100 will be awarded to the scheme selected by the Council as the most suitable for the requirements of the borough. Plans and particulars to be sent before 1st December, 1893. A print of the conditions of the competition will be forwarded on application to Mr. R. Borrough Hopkins, the town clerk.

Manchester Tramways. — Mr. Alderman King, addressing the shareholders of the Manchester Carriage and Tramways Company on Tuesday, said that, with regard to the motive power, the directors had seen no reason to make any change. He stated that Manchester did not want the unsightly steam-cars of Bradford and Leeds, and as to electric power, they had no evidence yet it was likely to pay. The directors would, however, seek to pursue a policy which, while safe, was progressive.

A Club-Cafe.—A club-café has been opened at 78, Strand, W.C., the object of the management being to make the establishment a club without a subscription. The Exchange Telegraph Company's tape and column printing-machines are provided, and market quotations and other matters can be seen throughout the day free of expense. In addition to this, telephone and District Messengers' Call Service are at the disposal of users without any charge. The establishment, which is lighted throughout

by electricity, should be inspected, so that an opinion of its advantages may be personally obtained.

Lighting at Manchester.—It appears that the Manchester station has not yet been put in proper working order, several hitches being reported to have occurred which have put users of the light to considerable inconvenience. In several instances the annoyance has been all the greater because the gas fittings had been removed and there was no gas to fall back upon when the other light failed. In one case the failure of the light was due to the careless conduct of two men, who were at once dismissed; and in other cases it was due to slight mishaps such as are incidental to the early stage of a large station. An installation of the electric light at the Reference Library has just been completed, the current being supplied from the Corporation central station.

Train-Lighting.—As mentioned in our last issue, the directors of the London, Brighton, and South Coast Railway have given instructions for the equipment of 10 more trains with the electric light. This will make a total of 40 trains so fitted. The superiority of this method of lighting is very marked, and it affords much satisfaction to those working the traffic. Especially is the benefit felt in busy times and foggy weather, when under ordinary circumstances gas-lighted trains would have to be specially sent to the charging stations or put out of working altogether. It is estimated for the above-mentioned reasons that at least 15 per cent. more work is got out of electrically-lighted trains than with those lighted by gas. This, simply in the construction of, say, 100 trains, would mean a saving of something like £45,000 in first cost—*i.e.*, 85 electrically-lighted trains would do the work of 100 gas-lighted trains.

Brewers' Exhibition.—A large selection of engineers' stores and tools is shown at the Brewers' Exhibition by Messrs. W. H. Willcox and Co., of 34 and 36, Southwark-street, S.E. The company having taken over the Farringdon patent pumps, patent Penberthy injectors and ejectors, also sight-feed lubricators, steam cocks, etc., from Messrs. Pontifex and Wood, Limited, of Shoe-lane, E.C., who have given up this part of their business to Messrs. Willcox, the latter thought it would be the means of bringing these goods before the brewing interest, as they had been large consumers of these articles from Messrs. Pontifex and Wood. This trade is being continued by Messrs. Willcox, who also have on view a selection of engine packings, indiarubber goods, hose, asbestos, etc., also leather belting, cylinder, engine, lard, neatsfoot, dynamo, and other lubricating oils, the usual assortment of sundries, including steam-gauges, sight-drop lubricators, gauge glasses, oil-cans, vices, forges, bellows, bolts, nuts, nails, etc.

The Madras Electric Tramway.—As mentioned in our last issue, work at the site of the generating station has been commenced, and it will be pushed on rapidly. The erection of the buildings has been undertaken by Messrs. T. Jones and Dumphy. The car-sheds will be constructed to hold 30 cars, and admit of extension to accommodate 20 more. The connections with them will be made with the main line on the Poonamallee-road, and the lines in the sheds will be intersected with examination pits to allow workmen to get at the car motors. The engine-room will contain four sets of Tangye's compound coupled non-condensing engines of 180 nominal horse-power each. These will drive four Elwell-Parker dynamos, the output of each of which will be 240 amperes at 500 volts; and there will be two smaller dynamos by the same makers. The boiler-room will be equipped with a battery of six Babcock and Wilcox boilers, a Berryman heater, donkey pumps, filters, and overhead water-tanks. The whole of the premises will be lighted throughout by electricity. The whole structure, when completed, will form one of the interesting features of Madras.

Miners' Electric Hand Lamps.—We have already referred to the Sussmann miner's electric lamp, which has now been described by a Newcastle paper. With regard to the latter description, a correspondent states that the fact has been overlooked, and which is also ignored by many expert people, that a safety lamp has usually to be carried by a breathing machine called man. Continuing, the writer says: "The gases met with in mines are not characterised by any property of rendering themselves perceptible to any of the five human senses; and the combustion carried on in a lamp is generally the only guide by which a man can judge of his own combustion. An electric lamp will give a splendid light while its too confiding owner is being smothered. It will illuminate just as well the bottom of the sea, but affords no 'safety' for a man to carry it there. If appliances were added to an electric lamp so that it would automatically give warning of the presence of either black-damp or fire-damp without requiring the making of any special observation, then we would have a more or less perfect 'safety' lamp. That the ordinary safety lamp causes 'miner's nystagmus' I thought had been disproved by Snell, who, I believe, arrived at the conclusion that the complaint arose from fatigue of the eye muscles induced in those whose occupations allow more or less oblique and upward gaze."

The Electric 'Bus is Coming.—Some of the daily papers have been interviewing an official of the Pioneer Electrical Carriage Company—whose formation we lately chronicled—and upon the somewhat slender basis afforded by such details as the above-mentioned official found it wise to give, a very airy superstructure has been reared. Tramways are to be a thing of the past as soon as the new contrivance comes into general use; and the whole "world of road-locomotion revolutionised and recreated." That, of course, is easily done in an evening newspaper, but on enquiring as to the amount of exaggeration in this report from Mr. Frank King, manager of the Electrical Power Storage Company, we were assured that the task has not been so readily accomplished in practice. However, some progress has undoubtedly been made, and Mr. King himself feels sure of ultimate success, not only in the use of the special form of pneumatic wheel (enlarged upon by the newspaper man in such grandiloquent style), but also in the driving and steering of cabs, omnibuses, and similar vehicles by means of electricity derived from storage batteries. When the matter is fully ripe we shall be able to give our readers the complete particulars; meanwhile it is enough to say that the electric omnibus, though well on the way—perhaps, even half constructed—is not yet finished, and therefore not ready for actual work.

City and Guilds of London Institute.—The annual report of the examinations department of the City and Guilds of London Institute, signed by Mr. G. Matthey, chairman of the committee, and Sir Philip Magnus, superintendent of examinations, which has just been issued, shows a considerable development in the work undertaken by the institute. The work of the department is carried on by 77 acting and 41 consultative examiners, all of whom are experts in their several trades. The examinations embrace all the principal industries of the country, and range from such subjects as electric lighting and alkali manufacture to plumbers' work and dressmaking. The institute is doing important work in endeavouring to raise the standard of teaching in the various trade subjects in

which examinations are held. The practical tests which the candidates are required to pass are carefully arranged with the view to the special branch of the trade in which they are severally engaged, and owing to the numerous sections into which trades are now divided, the organisation of these practical tests is attended with considerable difficulty. Thus, in mechanical engineering a candidate may elect to be examined in the honours grade as a fitter, a turner, a patternmaker, or a draughtsman. The practical tests are always held in connection with the written examination, and in many subjects form a necessary part of the qualification for a certificate.

Shiplighting.—The passenger steamer "Zaire," built by Sir Raylton Dixon and Co. for the Empriza Nacional Steam Navigation Company, of Lisbon, is constructed of steel, and is 350ft. long by 42ft. beam. The vessel is lighted electrically, including the masthead and side lights, the installation having been carried out by Messrs. Paterson and Cooper, under the supervision of Mr. E. G. Tidd, their engineer and manager in Scotland. The plant comprises a Robey vertical inverted cylinder electric light engine capable of developing 35 h.p. with a steam pressure of 80lb. The diameter of cylinder is 9½in. and the stroke 9in. The engine runs at 300 revolutions per minute, and is fitted on the same bed-plate with a new type Phœnix dynamo with the spindle coupled direct to the crankshaft of the engine. This dynamo gives 18,000 watts in the external circuit, and is of an inverted type with wrought-iron magnets and Gramme wound armature. The total number of lamps installed is 315, all of which, with the exception of 22 of 50 c.p. fitted in the engine-room, are of 16 c.p. The installation is divided into six circuits. The fittings in the saloon are somewhat of a new departure, being made of real bronze metal, with rich cut-glass globes, and are expected to wear much better than the plated fittings usually seen in ships' saloons, besides giving a most pleasing effect against the marble decorations. The first-class accommodation has plated fittings, with cut and etched globes, while the second-class has brass fittings with opal globes. All the switches and fuses in these parts are of the tumler type, with covers to match the various fittings. A complete system of electric bells has been fitted throughout the boat.

A Dynamo Fault.—A correspondent of a German mining journal relates a curious story of a Lahmeyer dynamo. It appears that the machine, which had not been in use for some time, was brought into requisition and set to work. Just after starting slight sparking was observed; at the close of a two hours' run the sparking suddenly increased so rapidly as to burst out into a flame, the pressure at the same time falling from 120 to 30 volts. It was at first thought that a short-circuit had taken place on the line, which was 330ft. long, and parallel to which an iron wire was carried for some distance. The line was, however, found in order, and it became necessary to look elsewhere for the fault. After many tests had been made in vain, the dynamo was again started, and after half an hour's run the heavy flamelike sparking was repeated. The insulation between the commutator segments was then scratched out by means of a sharp tool, and the fault was discovered and remedied by turning up the commutator. The cause of the fault was as follows: Owing to the dynamo not having been used for a long time, the insulating material, consisting of pasteboard between the commutator segments, had absorbed moisture from the atmosphere and rendered the narrow surface on the top of the insulation capable of retaining the brass dust thrown off by the brushes. The extraordinarily fine metallic dust was found to be embedded deeply into the surface of the insulation, and so converted it into a conductor. The conductivity was further increased by the fact that on the dynamo being set in operation, the warming of the commutator caused the segments to expand and exercise a strong pressure on the insulation. In this way a short-circuit arose between the individual segments, and this caused the flamelike sparking to take place.

The Reduction in the Price of Lamps.—With regard to the forthcoming expiration of the incandescent lamp patents, a representative of the *Pall Mall Gazette* has had an interview on the subject with Major Flood Page, the deputy-chairman and late general manager of the Edison-Swan Company. Concerning the statement that cheap lamps are coming over in shoals from abroad, the major said that there may be a slight spurt at the first, because, no doubt, some people have been holding back; that the cost of lamps compared with the cost of a central station is extremely small; and that the saving effected by a reduction in the lamps would be still more minute in comparison. Continuing, Major Flood Page said the foreign lamps although cheap, and in some cases fairly efficient as light-givers, are likely to have one serious drawback—they will not last, and the governing principle with users is to renew as seldom as possible. The British public will feel aggrieved if it buys cheap lamps and finds that they will not burn half as long as the old ones. In the West-end, and other parts where houses are shut up half the year, there are lamps which have lasted as long as three years without costing a penny for renewals. With regard to competition, the company will not try to undersell the cheap German lamps that will come over. He is only afraid that they will do more than this, and discredit electric lighting in general; for he believes that all sorts and kinds of refuse lamps, "misfits," as it were, are being collected for our benefit; and there are likely to be accidents in consequence of their use. The repeated tests made with every individual lamp turned out at Ponder's End is one of the chief items of expense in their manufacture, and one which no false economy would lead the company to cut down. It is this which helps to make the English lamp dearer than its foreign rivals, but which has made it at the same time so good. It takes six months to train a skilled hand. "Then we make all our own materials at Ponder's End, including glass and gas. We also control the patent lampholder, which everyone uses, and derive a large revenue from its royalties. We manufacture every kind of fitting and electrolier ourselves, and having so many departments of work can shift our hands about from one to the other as the demand on each varies. In this way we have reduced economy in the manufacture to a fine art, and, what is more important, can turn out our lamps with an equality and evenness which only long experience can give. There was a time when in order to produce 1,000 lamps of the same voltage and illuminating power we had to make 1,500. Now we can ensure 1,000 perfect lamps out of 1,025, or even less. If you consider how delicate the lamp is, and what a difference the slightest flaw or irregularity in the filament will cause, you will agree that this is a wonderful result."

Physiological Effects of High-Frequency Currents.—Writing to the *Lancet* of the 21st inst., in reply to a letter from Mr. Swinton, Mr. Wm. G. Sutherland, M.B.Aberd., says: "Mr. Swinton's letter in the *Lancet* of October 14 seems to throw no further light on this subject. The effects on the body are perhaps not altogether proportional to the magnitude of current passed and the density. In the case of the discharge from a Leyden jar we have a comparatively feeble current oscillating many hundreds of thousands of times per second, and at a potential of some thousands of volts, and yet such a rapidly-

alternating current gives rise to energetic physiological effects. Broadly speaking, an alternating current at ordinary frequencies acts chiefly on the nervous system; a continuous one acts more by chemical means, causing electrolytic decomposition of the contained saline fluids. Dr. F. Peterson, in a report of experiments read before the School of Mines, Columbia College, N.Y., on July 30, 1888, came to the conclusion that rapidity of alternation alone sufficed to make a current more destructive to life, a rapidly-alternating current being more deadly than a continuous one of double the voltage. This, we now learn from the recent experiments of M. Nikola Tesla and M. d'Arsonval, holds good up to a certain point only, and magnitude of current as measured in amperes seems to form the prime factor. Contrary to what obtains in the case of metals, the carbon filament of a lamp decreases in resistance as the temperature rises with an ordinary continuous or direct current. With an alternating current the resistance, on the contrary, increases until with currents rapidly alternating millions of times per second the effective resistance of the carbon filament is enormously increased. Hence, applying Joule's law ($H = C^2 R t$) to high-frequency currents, the resistance is enormous, while the current is proportionally small, and yet the total energy represented in watts consumed by the lamp is the same as it would be with a current of greater magnitude at a lower pressure. The volts are numbered by thousands, while the current is only a few milliamperes; but this only proves that so much energy was employed in bringing a lamp filament to incandescence. Is there evidence to show that this energy actually passes through the tissues of the body? With ordinary frequencies the resistance of the human body to an alternating current is less than to a continuous one of the same voltage—just as, in the case of carbon, as soon as the ordinary frequencies are exceeded the resistance offered to the passage of currents rapidly rises. Prof. Clerk Maxwell asserted, and Lord Rayleigh later on experimentally confirmed, the fact that with currents of high frequencies transmitted along metallic wires self-induction causes the current to glide over the surface of the conductor without penetrating to the interior at all. What obtains for metallic conductors may be equally true as regards the human body. The late Dr. W H. Stone, in the Lumleian Lectures, 1886, compared the human body subjected to alternating currents from an induction coil to a condenser, and asserted that with rapid intermissions it was probable that a current did not fully pass before it was neutralised, in whole or in part, by the succeeding current of opposite sign coming from the opposite direction.

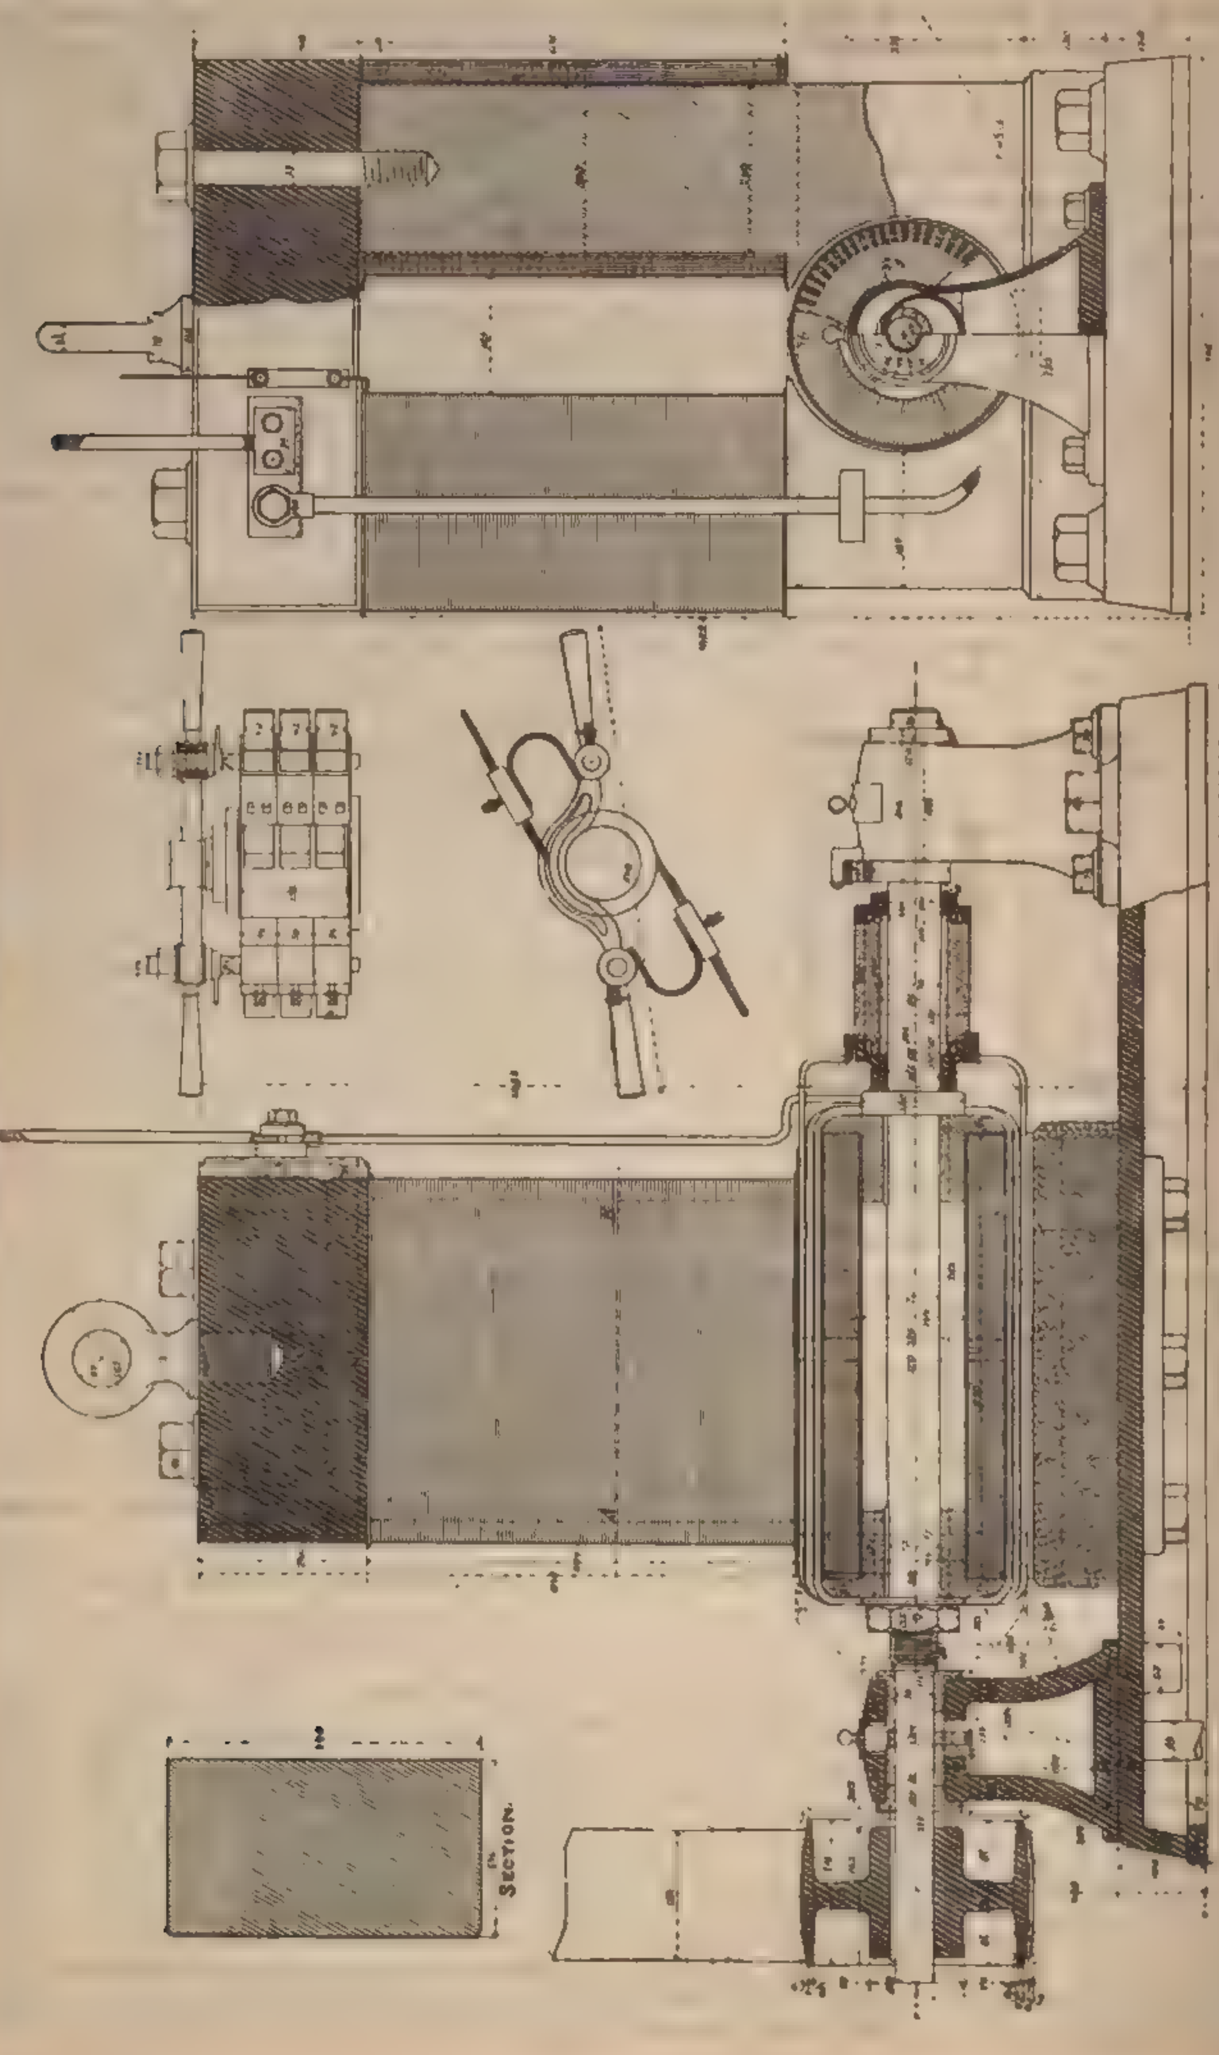
The Braking of Electric Tramcars.—Reference was made in a previous issue to the failures of car brakes on electric tramways in the United States, and now Mr. E. A. Sperry, in the *Electrical Engineer* of New York, deals with the problem of street-car braking. He states that as steam-road practice, road bed, speeds and weights are gradually approached, their experience in the solution of this most important problem should be studied with care. In so doing, however, the features wherein the street-car problem is differentiated from the steam-road problem should be kept prominently in mind. It must be remembered that the locomotive engineer is provided with a complete, expensive, and somewhat intricate apparatus with which to de-energise his train. The periods of its application are comparatively infrequent, and as to personal capabilities he is schooled and trained for years before ever being allowed to touch either the throttle or the triple valve. While working, his pressure gauges allow him to adjust the brake application to a nicety. The time element which is given for the total retardation and final stopping of his train is usually very large as compared with that allowed in street-railway practice. Of the two, the street-railway problem is the most exacting, and in the hands of far more inexperienced operators; and yet we are told that the mechanism involved in its solution must bear only a small ratio to the constantly decreasing cost of the total equipment. Mr. Sperry thinks this is hardly fair. He opines that the purchaser should be willing to spend money to effectually control the retarding car as well as the accelerating car. To be sure, as little expense should be incurred here as possible, but enough to fully meet the requirements. Its importance at once commands the attention of all, and commends the problem as such to the engineer. Considering the inexperience of the operator and the responsibility which at times well nigh overwhelms him, he thinks that, as engineers, we should be willing to set a very high mark to be attained in the ideal brake for electric street-railway service—namely, the use of but a single controlling handle for everything: starting, accelerating, retarding, and braking; the trailer or trailers and all. Let the motorneer have nothing to think of except one handle, and two-thirds of the accidents now occurring will be prevented. Let this handle require no more exertion in its operation than the present controlling handle. Let the motorman fulfil his functions with as little physical exertion as possible; he will have a greater reserve for mental application when necessary. A motorman required to exert an enormous amount of brute force, constantly grinding at the brake, has but little life left to apply in case of emergency. He agrees with a prominent writer of a year or so ago on this subject, where he says that a multiplicity of handles is fatal in time of emergency. Were you ever present at an accident? Mr. Sperry has seen the motorneer unconsciously turn the handle the wrong way when "rattled" and frightened by a terrible exigency in which he suddenly found himself, with consequences that were too horrible to reiterate. The motorneer was blamed. Who would have done better under the circumstances? In the author's judgment that motorneer was not so much to blame; he was handicapped. Many may think the mark that he has herein set is too high for attainment. In his judgment, however, he does not think it is. Of course the problem is a hard one, but almost every attainment of value has been reached along this same route. This emergency is our opportunity. Let us give the struggling street-railway man at once a practical solution of the problem, being satisfied with nothing short of the ideal simplicity named, bringing up thereby the advancement in the brake to the high standard of excellence attained by the application of the power.

Gauging of Alternate-Current Voltmeters.—One is often placed in a difficulty, writes M. E. Meylan in *L'Electricien*, in laboratories or workshops when it is desired to obtain alternating E.M.F.'s and the feeble current necessary in gauging alternating-current voltmeters, or for other purposes. One method, adopted by MM. Hospitalier and Roux in the laboratory of the Ecole de Physique et Chimie, in Paris, consists in driving the alternator by an electric motor energised from a battery. The following method, according to M. Meylan, is very simple, and can be used to great advantage: In a dynamo, or an ordinary continuous-current motor, any one segment of the commutator passes successively over all ranges in the difference of potential comprised between zero (if the machine has one part connected to earth) and the maximum voltage of the machine—say, 100 volts, 150 volts, etc.—and then again pass from zero in one revolution of the machine in the case of a bi-polar dynamo. If, then, any two segments of the commutator are connected to two

insulated rings, it will be possible to obtain an alternative difference of potential at the two brushes, or collect an alternating current, which is produced by the working of the motor. The frequency of this current is equal to the number of revolutions per second. The useful voltage collected at the two brushes depends upon two factors: the relative disposition of the segments of the commutator connected to the rings and the disposition of the magnetic field. By taking two segments diametrically opposite on the commutator the maximum difference of potential is realised. The relation of the alternating voltage to the voltage at the brushes (for a very feeble output) depends upon the form of the magnetic field. The only practical difficulty arises from the fact that it is necessary to obtain extreme angular speeds to reach practical frequencies. In fact, the frequency of 60 (40 is the lowest used in practice) corresponds to a speed of 3,600 revolutions per minute; the frequency of 100, which is largely used in England, is equivalent to 6,000 revolutions, and the frequency of 125, as employed by the Thomson-Houston and Westinghouse people in the United States, corresponds to 7,500 revolutions per minute. These speeds are much higher than one is accustomed to consider in practice, and a special plant is necessary to obtain them. Nevertheless, as the power furnished is very weak, since it only concerns some hundredths of an ampere, it is sufficient to have a small well-constructed dynamo so that there will be no danger. A small Perret motor, used by M. Meylan, ran at 1,600 revolutions, giving 120 volts, and up to ½ h.p. Leaving the exciting out of consideration, it would have been necessary to apply an E.M.F. of from 360 to 400 volts to drive the motor at 5,000 revolutions, but this is not very practical. A liquid rheostat was therefore inserted in the inductive circuit, and this enabled the exciting to be reduced three or four times. Under these circumstances a pressure of 180 volts gave a speed of 5,500 revolutions. By adjusting the rheostat the frequency may be very easily varied, this proving very useful in the investigation of alternating-current voltmeters. It is, of course, necessary to regulate carefully the brushes so as to avoid sparking under these conditions. Thus, with a small motor and a battery of accumulators capable of giving a fraction of an ampere one can produce at will, by a simple manœuvre of the commutator, alternating E.M.F.'s with a feeble output by varying the voltage from a few volts up to 100 or 130 volts with any frequency easy of measurement. On completing the system, by a small transformer one can easily obtain several thousands of volts constant for verifying high-tension electrostatic voltmeters. This arrangement, M. Meylan concludes, is the most practical, and is specially suitable for laboratories and for workshops where measuring instruments are made.

The Proposed Pacific Cable.—The *Times* of Monday states that Mr. Sandford Fleming has left Canada for Australia with the view of submitting four alternative routes for the proposed Pacific cable from Vancouver. Mr. Sandford Fleming's name has been for many years associated with the scheme of connecting the Empire right round the world by a cable of which the landing stations should be everywhere in British hands, and it will be remembered that on behalf of the Colonial Conference of 1887 he won the sympathy of many of his colleagues for the scheme for the construction of a Pacific cable which he laid before them at that time. The Canadian Pacific Railway had then been in existence for about a year, and Mr. Sandford Fleming urged that the creation of this first important link in the chain of British communication through the continent of America was a fact that ought to be utilised in the interests of Imperial unity, by continuing the chain across the Pacific till it touched British territory again upon the further shores. There were, he pointed out, three ways of carrying out this idea, the third being the construction of the Pacific cable from Vancouver, *viâ* Honolulu and Fiji, to Australia. The colonial Governments on either side of the ocean are willing to contribute subsidies towards the construction of the cable, and the supporters of the scheme on the Canadian side look anxiously for the help of the Imperial Government. In despair of obtaining it, some of the Australian Governments have agreed to subsidise the French line, of which the Société des Télégraphes sous Marins (as mentioned in our last issue) has already completed a first section from Queensland to New Caledonia, but the general feeling is that this has been a false step, and is likely to hinder rather than to help the construction of a through British cable. A cable which passes through French stations in the Pacific could not expect to be subsidised for Imperial purposes. It must base its chances of success wholly on the commercial prospect, and if this justifies its construction, the existence of one Pacific cable already monopolising such business as there is will for a long time to come prohibit the creation of a second. The scheme of the French company's cable can only be acceptable to the English communities concerned on the assumption that no British cable is to be hoped for. If a British cable is to be made, it must be made before the French company has decided on the full extension of its lines to the American coast, and until this possibility is definitely rejected the colonies of Victoria, South Australia, and New Zealand join with Canada in withholding their support to the French line. The prospects of cable business depend, of course, to a great extent upon the business done by the shipping lines. What this is likely to be has been made clearer of late by the investigations of the interchangeable commodities of Canada and Australia, made on behalf of the new line of steamers established by Messrs. Huddart and Co. All the information which was required to justify the venture of the ships serves to define the prospects of the cable as far as its purely commercial aspect is concerned. The trade of the four-and-a-half millions of Canada with the three-and-a-half millions of Australia hardly seems at first sight likely to repay the heavy cost of the construction of 6,000 miles of cables. Nor is it, indeed, probable that a cable line could at first exist without large subsidies. But it has to be remembered that telegraphic communication, once established, is not for this generation only. All that can be said on the score of insufficient trade might have been said at the first conception of the other great cables of the world. It is now stated by the supporters of the scheme that the technical difficulties of the course which it is proposed to take are nowhere so great as they have been represented to be, and that the laying of the line offers no special obstacle to the realisation of the project. It is understood that the schemes which Mr. Sandford Fleming is about to lay before the colonial Governments of Australia ask only for a collective subsidy of £60,000. What is now wanted in order that the project may be fairly judged is precisely what it is understood that Mr. Sandford Fleming's mission to Australia is to effect—namely, a clear exposition of some practical scheme for its fulfilment. Mr. Sandford Fleming will have a strong ally in Australia in Mr. Bowell, the Dominion Minister, whose visit will be contemporaneous with his own. Sir Thomas M'Ilwraith, the retiring Premier of Queensland, said the other day that Queensland always favoured the construction of a purely British cable across the Pacific, and would warmly welcome the support of the mother country to such a scheme. We believe this matter is now attracting the attention of the English Government.

DETAILS OF AN EDISON DYNAMO.



The above illustration gives the details of an Edison machine with drum armatures. The measurements are metric. Output, 30 kilowatts at 800 revolutions per minute. The pressure is 125 volts.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.*

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

XIII.

(Continued from page 239, Vol. XI.)

RESISTANCE, *continued.*

Differential Galvanometer.—This type of instrument is, of course, properly classed, not under the head of resistance but of current measuring instruments, as its function is primarily to compare and measure differences in currents of electricity. Owing, however, to its great adaptability for measuring, or rather comparing resistances, a reference to its adjustment and applications to this special purpose will not be out of place under the heading of resistance-measuring instruments; while the construction of the instrument itself, and its various applications to the measurement and comparison of currents will be given when these types of measuring instruments, known as "electrical balances" (to which class the differential galvanometer really belongs) are being dealt with.

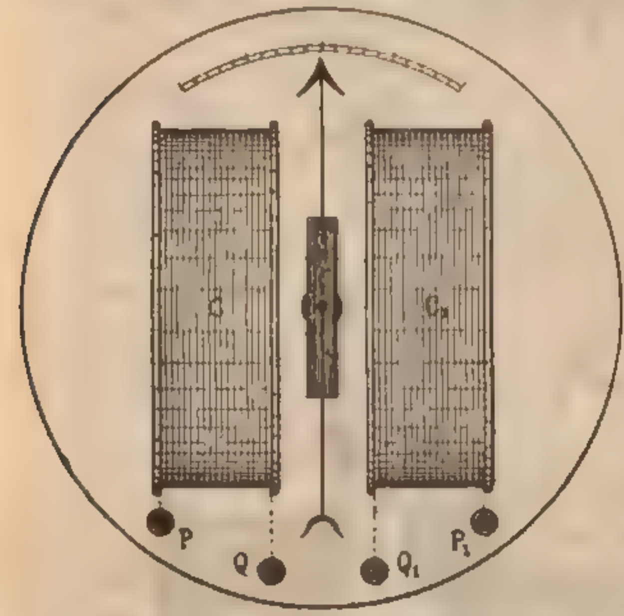


FIG. 33.—Differential Galvanometer—Plan View.

The differential galvanometer, of which the main features are shown in Fig. 33, consists essentially of a magnetic needle freely suspended in the vicinity of two precisely similar coils of wire, C and C_1, so placed that they both influence the needle to an exactly equal extent when the same or equal currents are passing through them. The terminals of the two coils, P & Q and P_1 & Q_1, are so arranged that the coils can be connected up in series or in parallel, or can be entirely disconnected from each other, according to the requirements of the case. The instrument is usually provided with a set of shunts whereby the sensibility of either or both coils can be varied to any desired extent, the usual ratios employed being

$$\frac{1}{10}, \frac{1}{100}, \frac{1}{1{,}000}.$$

Figs. 34 and 35 illustrate diagrammatically two different methods of connecting up the galvanometer coils, battery, contact-maker, known variable resistance, and the unknown resistance. In Fig. 34 the two galvanometer coils, C and C_1, are connected up in parallel, the one coil C_1 being in series with the known variable resistance R_1, while the other coil C is in series with the unknown resistance R. Whenever R_1 has been so adjusted that the galvanometer needle shows no deflection on the circuit being completed by closing the contact-maker K, the currents flowing through the two coils, C and C_1, must be exactly equal, as they are in opposite directions and just neutralise each other's effects on the needle. But if the currents are equal, the total resistances in the two sections of the divided circuit must also be equal to each other, and therefore as the resistance of C is equal to that of C_1 it follows that

$$R = R_1.$$

With the other arrangement, shown in Fig. 35, the two coils, C and C_1, are in series with each other, the battery, the contact-maker, and the two coils all forming one circuit. The known resistance R_1 is connected up as a shunt to C_1, the one coil of the galvanometer, and the unknown resistance R is similarly connected as a shunt to the other coil C. Here, again, when the known variable resistance has been so adjusted that the closing of the circuit causes no deflection of the galvanometer needle, we have an equality between R_1 the known variable resistance, and R the resistance being tested; for in order that precisely equal currents should be passing through C and C_1, they must both be shunted to an exactly equal extent, and therefore we have again

$$R = R_1.$$

When the unknown resistance R is large compared with the resistance of one of the galvanometer coils, the former of the two methods, in which the coils are in parallel, is the most sensitive, and when R is small compared with the resistance of the coil, the second method, in which the coils are in series and shunted by the resistances, will be found preferable.

In order to increase the sensibility and accuracy of the differential galvanometer, it is advisable to make the coils of high resistance, so as to minimise the error due to inequalities of the coils; and in order to make the readings more accurate, the contact-maker K should be a reversing

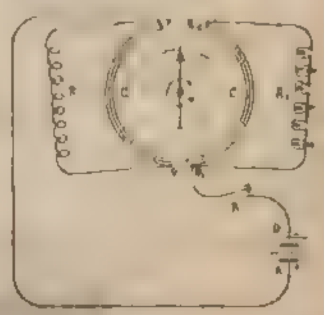

FIG. 34.—Coils in Parallel. FIG. 35.—Coils in Series.
Methods of Connecting up Differential Galvanometer.

one, so that the directions of the currents may be readily reversed through the coils of the instrument, and the mean of the two deflections taken.

(To be continued.)

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

DISTRIBUTION OF ELECTRIC POWER.

(Continued from page 294.)

TABULATION 30.

Conditions of Supply.		Two-wire.	Three-wire.	Five-wire.
Pressure in volts		100	200	400
Current in amperes		400	200	100
Total section of copper in sq. in.		2·0	1·25	·75
Total weight of copper in tons		2·08	1·30	·78
Percentage of loss of pressure		4·0	2·0	1·0
Percentage of loss of energy		4·0	2·0	1·0
Percentage of copper used		100·0	62·5	37·5
Percentage of copper used	with 4% loss constant	100·0	31·25	18·75
Supply distance in yards	with 4% loss constant	200	[illegible]	800

A summary of the three methods of low-pressure distribution is given above in Tabulation 30, in each case the power received from the generating source being 40,000 watts, none being tapped off along the line, so

that the whole of what is delivered is utilised at the far end, the distance served being 200 yards from the generating source. The last row of figures in the tabulation gives the increased distance the power can be sent, when the percentage of fall of pressure or loss of energy is kept constant.

High Pressure System.—We may now pass on to consider the second general system of distributing electric power—namely, by means of high pressure alternating currents. From the preceding figures it is seen that, generally, the higher the pressure employed the greater in proportion is the distance a given power can be transmitted and distributed, keeping the loss of energy constant; also, that for a given distance and loss of energy the weight of copper required will vary inversely as the square of the pressure employed.

This last law is, however, only theoretical, on account of making the loss constant for each case. The usual pressure used on high-pressure circuits is about 2,000 volts. Suppose we use 20 tons weight of copper to transmit 40 kilowatts a distance of 2,000 yards, with a loss of 40 per cent. or 16,000 watts, when a pressure of 100 volts is used. Then, if we used a high pressure of 2,000 volts, we should only require a current one-twentieth the amount; hence the sectional area, and consequently the weight of the new conductors, need only be one twentieth also—that is, one ton. But the loss of energy on the line is obtained by the expression $C^2 R$, so that although the resistance of the conductors increases while the current decreases, it must be remembered that the loss depends on the square of the current. Comparing the two losses, we have

with 100 volts, $C^2 R = 400^2 \times \cdot 1 = 16{,}000$ watts;
„ 2,000 „ $C^2 R = 20^2 \times 2 = 800$ „

so that the loss in the second case is only one-twentieth of the loss in the former. But the law states that the loss must be constant, so that the resistance of the 2,000 volt circuit must be either increased 20 times, or the resistance of the 100-volt circuit must be decreased 20 times; and this is where the result is absurd in a practical sense, because it would signify in the former a current density of 8,000 amperes per square inch, and in the latter case a density of only 20 amperes; the first would burn up the wires, while the second would be like burying money in the ground. The result, however, would be that the weight of the copper in the 2,000-volt circuit would be still further reduced to one twentieth again, and as it has already been reduced to one-twentieth before on account of the diminished current, this makes, finally, one-twentieth of one-twentieth, or one four-hundredth, so that using 20 tons with 100 volts, we should only require $20 \div 400 = \frac{1}{20}$ of a ton with 2,000 volts, thus exemplifying the theoretical law given above.

Neglecting to keep the loss of energy constant, and, instead, keeping the current density constant, we can then reach a practical solution, and this is, that the weight of copper used is inversely proportional to the pressure used, while at the same time the loss of energy becomes decreased in proportion as the pressure used rises. There is thus a great saving to be effected in the use of high-pressure currents, for not only is the weight of copper decreased, but the loss also. Applying this practical law, we find that the cost with a 100 volt circuit would be, say, $20 \times 60 = £1{,}200$ for copper, whilst with 2,000-volt circuit the cost would be only $1 \times 60 = £60$, and the loss of energy only one-twentieth of the loss in the former instance.

Although these advantages are very great and of a substantial nature, so far as concerns financial matters, it must not be thought that there are no drawbacks to the use of the high pressure system. The greatest of these, and the one most troublesome to deal with, is that of reliable insulation. The greater the pressure at which an electric current is driven along a conductor, the more difficult is it to confine it to the conductor and so prevent leakage. It is comparatively easy to well insulate a cable that is worked at 100 or 200 volts pressure, and the indiarubber covering need only be fairly thin, and hence inexpensive, but when dealing with 2,000 volts, heavy and very expensive covering is absolutely necessary, so that, roughly speaking, a 100-volt main is composed of a thick copper conductor with a thin covering, whilst the 2,000-volt main is a thin wire with a covering composed almost entirely of guttapercha and indiarubber, and having a depth perhaps twice as great as the diameter of the conductor. The cost of a cable is composed of two factors: (1) the cost of the mass of copper therein, (2) the cost of the insulating covering on the copper. In the case of low-pressure distributing cables, it is evident that the cost of copper as compared with the cost of insulation is high, while with high-pressure cables the cost of copper, as compared with that of insulation, is low, so that the ratio between the two varies greatly and inversely. For example, if we transmit 40 kilowatts of electric power at 100 volts one mile, we might use a cable costing £1,800 per mile, while if we transmit the same power at 2,000 volts pressure, we should use a cable which would only cost about £300 per mile. In the latter case the weight of copper is only about one-twentieth the weight used in the former case, and yet the total cost of the latter cable is one-sixth of the former.

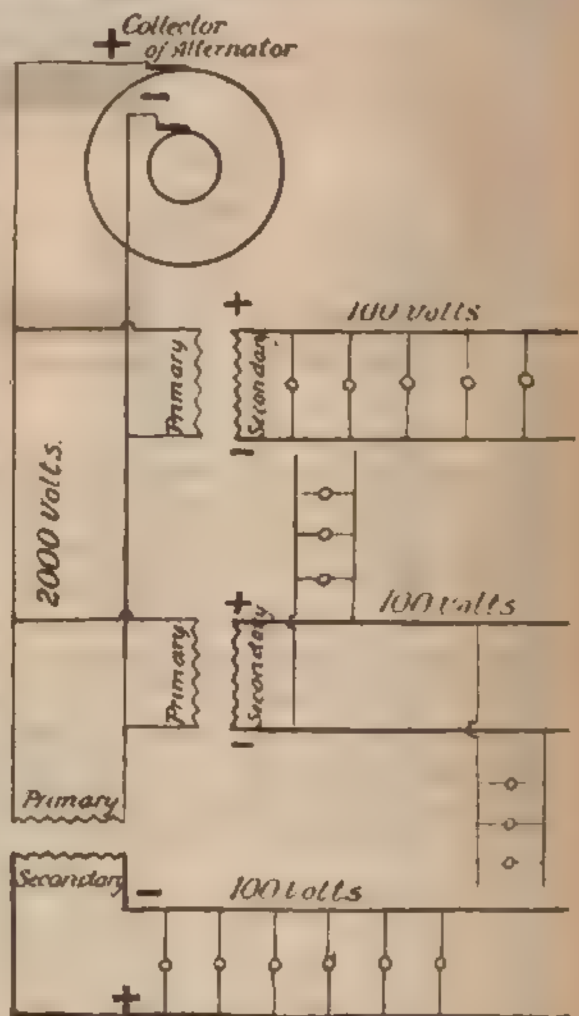

Fig. 31.

Fig. 31 shows how connections are made on a high-pressure alternating-current system. On an alternator, as already explained, there is no commutator, and the two ends of the armature wires are led to two rings, or "collectors," fixed in the armature shaft, each well insulated from the shaft and from each other. A couple of brushes are fixed on each collector, and the two circuit wires are led from the two collectors, as shown in the diagram. One is marked + and the other − in order to distinguish the two, although the polarity of the machine is constantly changing from + to − and back again. The two line wires are of small diameter, but thickly insulated, as only small currents are used. This thin wire and any tappings that may be taken off in parallel is named the "primary" circuit, and the two terminals of the fine wire or primary coil of a transformer are joined up to the primary circuit. This coil is indicated by the thin zigzag lines, the thick zigzag lines drawn opposite it denote the thick or secondary coil of the transformer, and its terminals are therefore connected on to the

thick wires of the secondary circuit, or lamp circuit, from which the lamps are run in the usual parallel way.

The pressure in the primary coil of the transformer is that of the primary circuit namely, 2,000 volts; while the pressure in the secondary coil and secondary circuit is only 100 volts, so that the function of the transformer is to receive a small current of high pressure and to send out a large current of low pressure.

(To be continued.)

DESIGN OF ALTERNATING-CURRENT MOTORS.*

BY EMIL KOLBEN.

There is no essential difference in the design of a single, two, or three phase motor, and, in order to simplify matters, we shall treat the problem for the single-phase motor only, noting, at the same time, the way how to apply the results to the design of motors of the multiphase type. We shall also consider the following typical form only, it being the simplest, the cheapest, and most economical, and therefore of chief commercial interest and value. It consists of two essential parts: 1. The external, stationary, inducing part or "field," A (see Fig. 1), made of a subdivided iron body, with a continuous ring or drum winding embedded in grooves or holes, and wound so as to form two, four, or more poles. 2. The internal rotating induced part, B, the armature, with a winding closed in itself. This latter may be arranged with the bars connected all in multiple arc (Figs. 2 and 3, Dobrowolsky's arrangement), or wound with a number of sections independent of each other (Figs. 4 and 5), each section with a ring or drum winding, made so as to form as many poles as are formed by the external field winding. The first arrangement can be treated as a special case of the second.

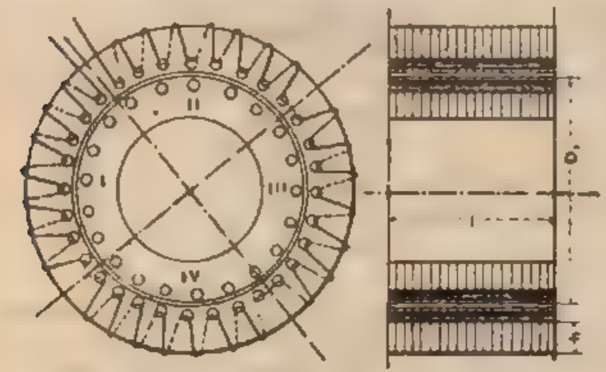

FIG. 1.

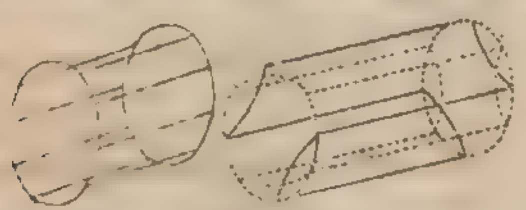


FIGS. 2 AND 4.

Let it now be required to design an alternating-current motor of the single-phase type, to deliver a power of P effective mechanical power units (horse power) equal to $W_1 = 736$ P watts at its pulley: Required to find the iron dimensions of the field and the armature, the number of turns, and the sizes of wires of the inducing and the induced circuits at a given impressed E.M.F., and, finally, the efficiency of the motor.

The first point to settle upon is the axle speed of the motor, V. This is determined by the frequency of n periods per second and the number of pairs of field poles, p. From these we find the number of revolutions per minute:

$$V = \frac{60\, n}{p} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The motor will have very nearly this theoretical speed when it is running free. At full load we shall allow a slip of $\frac{1}{s}$, so that the speed of the motor when it is loaded is $V - \frac{V}{s} = V\left(1 - \frac{1}{s}\right)$. If, for example, the slip is 4 per cent., then $\frac{1}{s} = \frac{1}{25}$, and the full-load speed $\frac{24}{25} \cdot V$. Thus we find a circuit of low frequency of 50 cycles and for one of high frequency of 130 cycles the following theoretical speeds:

Number of poles of motor.	V at 50 cycles (revs. per minute).	V at 130 cycles (revs. per minute).
4	1,500	3,900
6	1,000	2,600
8	750	1,900
10	600	1,560
12	500	1,300
16	375	975
20	300	780

From this simple comparative table we draw at once the important conclusion that the low frequency is preferable for the design, as it permits of reducing the number of

FIG. 3.

poles. At 50 cycles we can limit this number to between four and eight for motors from 1 h.p. to 50 h.p., while we need for the same sizes 10 to 20 poles at the high frequency of 130. We shall see later on that the idle or magnetising current increases directly with the number of poles, and this fact is no doubt one of the main reasons of the difficulty of designing good motors for high-frequency circuits.

I. *Design of the Field.*—The important question to consider is the proportion between iron and copper weight in the field. Similar considerations as in the design of trans-

FIG. 5.

formers may take place. The maximum induction density, B, in the iron is given by the frequency, the permissible loss, and the heat-radiating surface. B will in general be the same as in well-designed transformers, and it is advisable to take the following values:

For 40 cycles	B = 6,500 to 5,500
" 50 "	6,000 to 5,000
" 60 "	5,000 to 4,500
" 80 "	4,500 to 4,000
" 100 "	4,000 to 3,500
" 120 "	3,500 to 3,000

It would not be difficult to find by theoretical investigations the best relation between the weight of iron and copper, but by experience on a large number of designs I found that with the normal values of the induction in the iron an empirical constant can be found, by means of which the number of field turns, N, can be easily chosen.

This constant, C, is the number of ampere-turns per

* From the *Electrical World*, New York.

centimetre circumference of the bore of the field (or of the diameter of the armature, as the two are quite nearly equal). Let D_1 centimetres be the armature diameter [it can be found from the permissible circumferential speed $U_1 = 1{,}500$ to 2,500 centimetres per second, and V by

$$D_1 = \frac{60\ U_1}{\pi\ V}\Big] \quad . \quad . \quad . \quad . \quad . \quad (2)$$

and I the $\sqrt{\text{mean}^2}$ value of the current in amperes at full load; then the constant will be expressed by

$$C = \frac{I\ N}{\pi\ D} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

For frequencies of 40 to 80 cycles and an induction density in the air-gap of 2,000 to 3,000 C will vary from 100 to 150. This rule, of course, is but "a rule of thumb," and has to be applied judiciously in each special case From (3) we find the number of field-turns:

$$N = \frac{\pi\ D_1\ C}{I} \quad . \quad . \quad . \quad . \quad . \quad (3^1)$$

In order to determine exactly the full-load current, the exact value of the magnetising or idle current, i, should be known beforehand. A method for calculating this will be given later on. But an approximation sufficiently accurate can after some experience readily be obtained by taking I a certain percentage larger than the true watt current $I = \frac{W_1}{\eta\ E}$, wherein η is the full-load efficiency of the motor, and E volts the $\sqrt{\text{mean}^2}$ value of the impressed E.M.F. of the circuit. Two or three phase motors will have a comparatively larger number of field-turns, as the resultant current of the phases must be taken in consideration. They will consequently be somewhat lighter.

FIGS. 6 AND 7.

The primary or inducing winding must be placed in holes or grooves uniformly all around the circumference, in order to reduce the air-gap reluctance to a minimum. The width of the gap is given by the mechanical consideration of sufficient clearance between rotating and stationary part only, and varies between one and two millimetres from the smallest to the largest sizes.

From the total number of turns, N (or wires, if drum winding is used), the maximum value of the total induction can be calculated after the well-known transformer relation:

$$B\ S = \frac{\sqrt{2}\ .\ E\ .\ 10^8}{2\ \pi\ n\ N} \quad . \quad . \quad . \quad (4)$$

wherein S is the effective cross-section of the iron. B has the values given above for the various frequencies. Of this total induction only a certain percentage will be useful by passing through the armature and inducing in its conductors currents which will produce the required mechanical torque between them and the stationary field. The other portion will form a stray field through direct leakage from pole to pole, chiefly on the external surface of the iron body, Fig. 4. This leakage will increase with the size of the gap, with the induction density in it and in the iron, and also with the number of poles. A ring winding will, of course, produce a larger leakage than a drum winding. The stray field increases with the increasing load, and reaches an enormous amount in starting of the motor, when the ampere-turns on the field are many times larger than at load. At the moment of starting the useful induction is therefore reduced to a minimum, just at the time when a maximum induction is most needed. Another source of leakage is the small iron bridges left between the holes for *the winding, Fig. 5.* By using a half-closed groove, as in *Fig. 6, this leakage can be made negligible.*

The useful total induction, Z, will therefore be expressed by

$$Z = x\ S\ B \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where x is a fraction less than unity. If the motor is running loaded at normal speed, x can vary according to the design from 0·95 to 0·70; the author has found the values by various experiments.

From the effective iron section, S, the iron dimensions, h and l (Fig. 1), are found by

$$S = 0{\cdot}85\ h\ l,$$

by making an allowance of 15 per cent. for the paper insulation between the iron discs. In order to determine the length of the field, l, we chose the maximum induction density, B_1, in the air-gap with the view that the magnetising current will increase in direct proportion with this gap density If the motor is wound for two p poles, then the effective iron surface of one pole will be $\frac{0{\cdot}85\ \pi\ D_1\ l}{2\ p}$ and the useful total flux through one pole:

$$2\ Z = \frac{0{\cdot}85\ \pi\ D_1\ l\ B_1}{2\ p} \quad . \quad . \quad . \quad . \quad (6)$$

From this we find

$$l = \frac{4\ p\ Z}{0{\cdot}85\ \pi\ D_1\ B_1},$$

and by inserting the proper value for Z from equations (4) and (5):

$$l = 0{\cdot}34\ \frac{x\ p\ E\ 10^8}{D_1\ B_1\ n\ N} \quad . \quad . \quad . \quad . \quad . \quad (7)$$

and

$$h = 0{\cdot}78\ \frac{B_1\ D_1}{x\ p\ B} \quad . \quad . \quad . \quad . \quad . \quad (8)$$

For 40 to 80 cycles and a small gap B_1 may be taken from 4,000 to 2,500. With these dimensions of the iron body and with the induction densities given, the iron losses by hysteresis and eddy currents in the field can be readily calculated. The total length of the copper winding and its resistance can also be found and the copper loss in the field thus determined.

II. *Design of the Armature.*—The problem of starting shall be considered separately. For the present let us assume that the motor is giving off its normal output of W_1 effective watts causing it to run with a slip of $\frac{1}{s}$ at a speed of $V\left(1 - \frac{1}{s}\right)$. If the motor was running at its theoretical speed then there would be no E.M.F. induced in the armature conductors, as then there would be no difference between the speed of the armature conductors and that of the rotation of the field induction. By virtue of the slip, however, an E.M.F. is induced in the armature conductors producing currents in them whose strength depends upon the value of the slip and the armature resistance, R_1. The mechanical work performed by the motor will depend upon these currents. They will produce in the armature conductors a certain watt loss, w_1, which, together with the slip, is at the same time a direct measure for the useful work performed by the motor.

Suppose the armature is wound in u sections of m conductors each, these m conductors being connected in series; each of the sections to be short-circuited in itself, independently of the rest. Let r_1 be the resistance of one conductor (including the connecting wires) and $R_1 = m\ r_1$, the total resistance of one section. At an induction density, B_1, produced by the field, Fig. 6, at the slip $\frac{1}{s}$ and a circumferential speed $U_1 = \frac{\pi\ D_1\ V\left(1 - \frac{1}{s}\right)}{60}$ the E.M.F. induced in m armature conductors connected in series each of the induced length l (Fig. 1), will be:

$$E_1 = \frac{m\ l\ B_1\ U_1}{10^8\ s} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

The copper loss in all u sections of the armature is thus

$$w_1 = u\ \frac{E_1^2}{R_1} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

As the motor runs with the slip $\frac{1}{s}$ against the load, the total watts delivered by the motor must be s times as large as armature loss—viz.:

$$W = \frac{E_1^2}{R_1} u s,$$

and as $W = W_1 + w_1$, we find the useful mechanical energy delivered at the motor pulley:

$$W_1 = \frac{E_1^2}{R_1} u (s - 1) \quad . \quad . \quad . \quad . \quad (11)$$

By inserting the proper value of E_1 from (9) in (11) and considering that $m u = N_1$, which is the total number of conductors all around the armature, we find the important equation for the useful motor output:

$$W_1 = \frac{N_1^2 l^2 B_1^2 U_1^2}{10^{16} u R_1} \frac{(s - 1)}{s^2} \quad . \quad . \quad . \quad (12)$$

and from this the resistance of one armature section:

$$R_1 = \frac{N_1^2 l^2 \bar{B}_1^2 U_1^2}{10^{16} u W_1} \frac{(s - 1)}{s^2} \quad . \quad . \quad . \quad (13)$$

The $\sqrt{\text{mean}^2}$ current in the armature conductors in amperes

$$I_1 = \frac{E_1}{R_1} = \frac{m l B_1 U_1}{10^8 R_1 s} \quad . \quad . \quad . \quad . \quad (14)$$

or expressed directly by the useful watt output:

$$\bar{I}_1 = \frac{10^9 W_1}{U_1 N_1 l B_1} \frac{s}{s - 1} \quad . \quad . \quad . \quad . \quad (15)$$

The formulæ (12), 13), and (14) speak a clear language, and from them we see clearly what factors determine chiefly the output of an alternating-current motor.

These equations are general, and in the case of a closed-circuit armature according to Dobrowolsky's design, Fig. 2, we have the special condition of $u = 1$, and the armature resistance has to be calculated with the view that all the armature conductors are connected in multiple arc through the two end rings.

(To be continued.)

ELECTROLYSIS OF SEA-SALT.

A very useful property is inherent in electrical processes—namely, of utilising common products. Water is used for generation of current, the air itself is utilised for ozone; and if not so common everywhere as mud, sea salt or sea-water is a fairly common commodity round the shores of our tight little island. We have mentioned the proposed use of sea-water as disinfectant at Havre and other ports—much needing it, to be sure. We may have something further to say about this in conjunction with the Hermite process when the time comes. Meanwhile there is an account in the *Bulletin International* of the Castner process of electrolysis of sea salt which may be interesting to electrical chemists.

Each cell in the Castner apparatus has two compartments, one of which contains the cathode, and the other the carbon anode connected at the bottom by a bath of mercury, which is without appreciable resistance; this is kept in motion by agitators, and rests upon a metal base kept cool by circulation of water. One compartment is filled with water and the other with a concentrated solution of the salt to be electrolysed—chloride of sodium, for instance—mechanically separated by the mercury, a partition, and a projection made of amalgamated metal. When the current passes, hydrogen is given off; this escapes, while the oxygen would combine with the mercury if it were not confined by the sodium, with which it combines to form soda.

If the efficiency of the apparatus were perfect it would be sufficient to start with a small amount of sodium, which would renew itself, but as the efficiency is never perfect (it is usually about 90 per cent.) this must be allowed for. For this purpose the dynamo is first connected to the electrodes so as to pass the current into the mercury until an amalgam is formed, holding about 2/1000 of sodium, after which the second group of electrodes is connected to the dynamo, generating, say, 90 amperes; then the second group is connected to a second dynamo, giving, say, 10 amperes, so that for 100 amperes passing one side there is only 90 amperes passing on the other, precipitating 90 per cent. of the soda theoretically due to the 100 amperes, and giving off the corresponding chlorine, while the composition of the amalgam remains constant at 2/1000 of sodium.

The same result can be obtained by passing the full current for one hour on one half of the apparatus and for nine hours on the other half, and by arranging the cells in series in such a manner as to accomplish this permutation successively in the various cells without changing the potential at the dynamo. With cells in parallel, however, two currents, as mentioned, are employed in proportions regulated by the efficiency of the apparatus.

The solution of sea-salt is renewed by adding solution divested of hypochlorites, and kept in continual circulation, the old solution being treated for the purpose and put into circulation again. The solutions ought not to contain sulphate of calcium or other impurity, as this considerably reduces the efficiency. The solution of sodium is drawn off by a pipe and replaced by water to maintain it at the degree of saturation desired.

The apparatus here is made with three compartments, with two anodes and cathodes in the middle compartment. Three pistons circulate the mercury. Very little mercury need be used—a layer of 3mm. is sufficient. Each of the three pistons displaces at each stroke all the mercury in the compartment, or about a quarter in the whole apparatus, so that the play of the pumps may be quite slow to renew the mercurial surface. The pumps may be replaced by balancing movement arranged to shift the mercury alternatively from one compartment to the other.

The Castner process consists essentially in the use of a mass of mercury continually agitated and traversed by a current in its passage from the anode to the cathode, which are separated by this mercury, so as to disengage from the mercury at the cathode a quantity of sodium precisely equivalent to that precipitated at the anode. This mercury practically replaces the ordinary diaphragms by completely separating the products of electrolysis without introducing any appreciable electrical resistance, allowing at the same time the anode and the cathode to be brought as near as possible together.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LIFTING WATER BY ELECTRICITY.

SIR,—We have a well about 23ft. deep with an inexhaustible supply of water. We wish to raise that water to a reservoir 500 yards distant, at an elevation of about 80ft. from the well.

Could an electric motor be worked by a cable to work a pump (or anything of a similar nature), if the power was leased from an engine 500 yards distant or from a water-wheel two miles distant?

The quantity of water to be raised daily would be 50,000 gallons. What power would be required?—Yours, etc.,

Chard, October 24. J. G.

CAN ACCUMULATORS BE USED WITH RAILWAY GENERATING PLANT?

SIR,—Will some practical reader give his opinion as to its being practicable to combine the use of accumulators with generating plant for an electric railway. The engine power to be sufficient when the cars are under weigh, but extra current is required from accumulators to ease the engine when cars start, so that the load may be as constant as possible upon the engine. The action must be automatic and not require watching. The present dynamos are compound wound.—Yours, etc., DOUBTFUL.

October 25.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence: Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

140 SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom ...	3s. 3d.	...	6s. 6d.	...	13s. 0d
Other Places ...	4s. 11d	...	9s. 9d.	..	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE "PALL MALL" v. HARNESS.

The title of this article is not meant to indicate that litigation has commenced between these contending parties, but merely that there exists a little controversy between them. Up to the present time, so far as we know, the writing has been all on one side, but we should dearly like to see a rejoinder. It would be amusing and instructive to see what answer can possibly be given. What is it all about? Our readers will remember that our contemporary the *Electrical Review* not long since found itself involved in a lawsuit because it ventured to criticise the apparatus sold and the methods of doing business by the company over which Mr. Harness presides. The result of this litigation was that the Medical Battery Company was mulcted in damages, and the *Review* had no real opportunity of bringing its case before the jury, and hence before the public. However, a smart writer in the *Pall Mall Gazette* seems to have hunted out this evidence, and has worked it up into a series of articles in that paper. There is no mistaking the meaning of these articles, for throughout a spade is called a spade. Practically, the outcome of the whole series is to say that Mr. Harness is not an educated man, is ignorant of the first principles of electrical science, sells apparatus that is worthless, getting as much as he can for it, and trading generally upon the credulity of mankind, and especially of suffering humanity. Our opinion of this system of trading and these appliances has often been expressed, and we are not so much concerned with Mr. Harness or his doings at present as with a broader question which the action of the *Pall Mall* will, we trust, help to solve. The technical Press with one accord has supported the action of the *Electrical Review*, but the technical Press could only prove troublesome to Mr. Harness, and not fatal till the gross subserviency of the political Press in the matter of advertising any quack nostrum was suppressed. Take the London papers alone, not to mention the country papers, and examine them. It will be found that columns, nay, whole pages of their advertising space has been occupied with the advertisements of electropathic belts, corsets, and other quack nonsense. These papers are supposed to be conducted by educated men, who can at almost any moment obtain the best advice, technical or otherwise. Their leader columns abound in religious, sentimental twaddle, assuring their readers that they love their fellow-men and would die to do them a service. The *Pall Mall Gazette* calls Mr. Harness a liar; we say that the men who pose as one thing in one part of their paper and as another thing in another part of their paper are worse liars. If Harness is perpetrating gross frauds, they are accessories to the action, and in our estimation ten times worse than the initiator of the scheme. The poor suffering beggar who reads these grandiloquent advertisements in the *Standard*, or *Chronicle*, or *St. James's*, or *Illustrated London News*, or any one of the well-known London papers which has permitted their insertion, reasons that there must be something in it or these papers would not give prominence to the advertisement. In a

sense we pity Harness, just as in a sense we pity all clever desperadoes, though we have no word to say in his favour: it is these supporters in the newspaper world that we condemn, root and branch. There is no pity, only contempt, for them. They will sell their souls for a sovereign. Their action is wilful and thoroughly understood. They close their eyes and open their pockets till public opinion is in some way or other roused, and then with a plethora of honeyed words explain that they had never troubled about these matters—it was something not in their department. We therefore give all honour and credit to the *Pall Mall Gazette* in pricking this huge blister, and trust, now that editorial eyes have been, and they must have been opened, that the advertising departments will be compelled to close their doors against such advertisements in the future. A quack may have all the desire in the world to prey upon his fellows, but he cannot do much if the Press closes its doors against him. Mr. Harness is not the only quack, his advertisements are not the only advertisements that are a disgrace, but it is too much to hope that the Augean stable will be thoroughly cleansed. We must be thankful for small mercies. We congratulate the *Pall Mall*; and although Mr. Harness is said to be going to vindicate his honour, and the *Evening News* seems inclined to support him in that it publishes "with pleasure" an exceedingly silly letter or circular sent broadcast to scientific men and learned societies, in which Mr. Harness asks for a "commission of investigation," we do not think the *Pall Mall* need fear the result. A "magnetic or electric corset," or whatever they call it, as sold by the Electric Battery Company does not want a minute's scientific investigation. Is "Mr. Harness" or the *Evening News* credulous enough to think scientific men are going to solemnly sit in investigation of things of that sort? But enough; if the *Pall Mall* can stop the advertisements it will have benefited the whole country, and will certainly stop the sale of these unscientific and useless appliances.

The preceding sentences were written before the *Pall Mall* of Thursday was seen, and we were glad to learn from it "that several newspapers have refused to be any longer the means of bringing Harness's wares before the notice of their readers." Further, the same issue corroborates what is said above, in that we are told "many of the victims whose letters have reached us assert that they would never have given the belts a trial had they not seen them advertised in papers whose respectability and reputation were above suspicion." The *Pall Mall* then goes on to excuse ignorance of what is advertised; but we maintain there is no valid excuse. The conductors of the newspapers know that the advertisements come from men outside the medical or electrical profession; they know, indeed, that they come from quacks, and knowing that, they ought to get technical advice—if the fact in itself is not held to be proof positive against the insertion of advertisements.

These articles in the *Pall Mall* may not be verbally correct—there may even be doubtful scientific statements, but the broad facts are there and cannot well be denied. The crusade begun ought to be continued with vigour till the plague spot is stamped out.

REVIEWS.

The Dynamo: Its Theory, Design, and Manufacture. By C. C. Hawkins, M.A., and F. Wallis, A.I.E.E. Whittaker and Co.

(Concluded from page 326.)

The magnetisation of iron forms the text of Chapter XII., and the knowledge of to-day is fairly summarised, especially those points that influence dynamo construction, such as permeability and hysteresis. The authors maintain that "permeability" "differs decisively from the analogous property of conductivity." In this, however, they can hardly be held to follow the most progressive electricians, who seem to be coming more and more to the view that magnetic and conductive phenomena do not "differ decisively." Hopkinson's experiments and Ewing's developments and theories are clearly given. A chapter on armatures follows, the matter discussed referring as much to mechanical as to electrical details. Thus we have information as to the strength of shafts, the methods of building armatures, Crompton's plan for getting rid of eddy currents and their evil heating effects, the connection with and the construction of commutators. Chapters XIV. and XV. deal respectively with the field magnets and the ampere-turns of the field, and are worth careful study, although we think condensation might have been practised with advantage. Still, it is better to repeat than to fail to drive home the point under consideration. The decrease of permeability with magnetisation is again insisted upon, hence to work with the field beyond the point of saturation is wasteful. The materials for the construction of and suitability for field magnets are discussed, as are the various types of fields adopted in practice, mechanical as well as electrical questions being constantly kept in view. We could wish the authors had assisted the reader by still more repetition, even at the cost of slightly increasing the bulk of the book. For example, take the commencement of Chapter XV., reference is made to illustrations in Chapter III., and again to Chapters III. and XII. The reader would be assisted by a repetition of these illustrations, especially as neither page nor number of figure referred to is given. Again, after such a decisive contention in Chapter XII., we might have expected something different from Ohm's formula in Chapter XV., page 287: "We may express the fundamental equation for the ordinary bipolar dynamo with its two air-gaps, one on either side of the iron armature, in the following form:

$$\text{"Total M.M.F.} = H_a\, l_a + H_g\, 2\, l_g + H_m\, l_m."$$

If this is not absolutely and without reservation of any kind whatsoever analogous to

$$E = C\,R,$$

we do not know what it is. Solely because this fact fails to gain recognition, we have to encumber our books and papers with equations which frighten folks by their seeming complexity; yet the equations are reducible to the simplest form. To us these funny equations are ridiculous. Just as well put another term into the equation while you are about it, and recognise that the armature core has a different magnetic resistance per unit area to that of the field magnet because there is less magnetic volume in the unit volume of the armature than of the field magnet. We take it that this must be so in that some space is occupied with insulating material in a cubic centimetre of the armature core, and no such space is occupied in the field magnet. What we want is the total magnetic resistance of the particular circuit we are dealing with, and not the separate resistances that go to make up that total, except as an analytic detail when we are endeavouring to design a machine with total resistance as small as possible. Given however, that we must be tortured with this cumbrous notation, the authors use it as deftly as anybody, and, as we say, have put a lot of really valuable matter in these

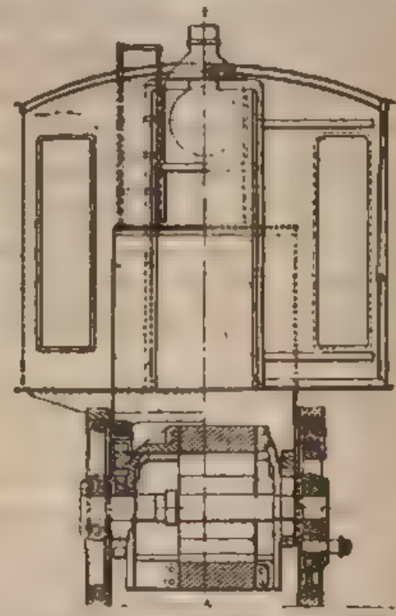
chapters, among which that relating to leakage is prominent. The description of the various kinds of winding, with the characteristic curves obtained, is next found, followed by a chapter on sparking and the angle of lead, in which is epitomised almost the whole of the existing knowledge on the subject. The careful reader will probably come to the conclusion that the best design of dynamo must be that in which the various compromises are most happily arranged. The whole is a question of give and take. After a chapter on heating of dynamos is given careful descriptions, with dimensions, of typical dynamos—a chapter of the utmost importance, for undoubtedly the designer will start from what is in existence, and modify these existing designs to suit his own requirements or foibles. Except we are to have a new departure, as suggested by Mr. Sayers, there does not seem much latitude for improvement in machines that give over 90 per cent. electrical efficiency. But the authors do more than describe machines; they show, in Chapter XX., how to design machines, using the information given in the previous chapters, and conclude with a chapter on the working and management of dynamos.

We have thus attempted briefly to indicate the contents of this volume—a volume in which the information given shows the authors to have ransacked the literature of the universe, and in a measure to have abstracted the wheat, though some readers will think there still remains a little chaff. The labour which has been spent upon this book can hardly be realised by those who do not know the trouble it takes to examine the *Transactions* of various societies, and to get at the pith of the papers contained in these *Transactions*. The book is well printed, amply illustrated, and furnished with a fairly good index. The motto of the authors in preparing a future edition should be condensation and simplification.

A POWERFUL ELECTRIC LOCOMOTIVE.

The scream of the American eagle is as a rule very offensive to many in this country who prefer slow but solid progress rather than undue or miscalculated haste, but the fact remains that while crowds gather together in England simply to look at an ordinary electric tramcar on the street, practical American engineers have taken a much greater step forward in electric traction, and are actually building electric locomotives of a very powerful type for special uses and purposes which do not involve great expense for new permanent way, etc., apart from the engines themselves.

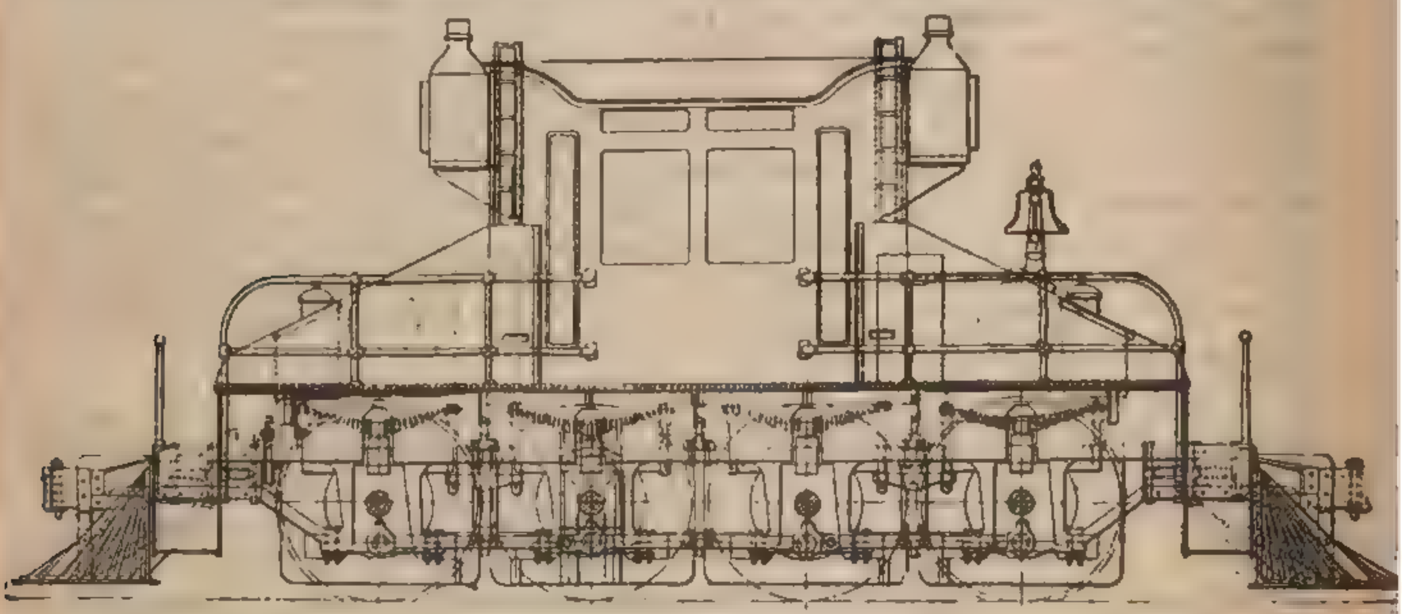
We have already chronicled — with full details and illustrations—the equipment of two large electric locomotives—weighing 30 tons and 90 tons respectively—by the General Electric Company, of Boston; and particulars are now to hand of another powerful engine, built to give an output of 1,000 h.p. The authors of this design are the well-known consulting electrical engineers of New York—Messrs. Sprague, Duncan, and Hutchinson—under whose supervision the locomotive is being built to the order of the North American Company. At first it will be used specially for experimental work in shunting and marshalling goods trains and waggons, being designed for that



Powerful Electric Locomotive.—End View.

purpose, with heavy traction at slow speeds. The armatures and electrical equipments generally are from the works of the Westinghouse Electric and Manufacturing Company, whilst the running parts, framework, etc., have been constructed at the Baldwin Locomotive Works, Philadelphia, where the whole engine is being erected.

The general features of this new locomotive are shown in the illustrations. The frame is of steel, with exceptionally deep pedestals, and is arranged to receive four pairs of boxes fitted with the usual adjustments. The pedestal boxes are of a special form, are made of cast steel, and project inward to form the brackets which carry the motors. The lower sides are arranged to be dropped out, so that the brasses can be readily replaced. These boxes render the double service of carrying the axles upon which the armatures are rigidly mounted and the field magnets concentric to them. A stirrup projects from the upper portion of each to engage the middle section of inverted elliptical



Powerful Electric Locomotive.—Side Elevation.

springs, the four sets of which are arranged on the double three-point suspension system. In this way the whole is carried on equalising springs.

The driving wheels are 56in. in diameter, the first and last pairs only being flanged. They are close coupled, with only 4in. between the faces, and the connecting-rods are jointed.

It will be noted that the weight of the armature is directly on the wheels, and not on the journals, while that of the field magnets is on the journals through the pedestal boxes. There is thus absolutely no spring support of any kind provided for any part of the motors. This is contrary to the prevailing opinion of what is necessary in a machine of this type, as, for instance, on the motor cars of the Liverpool Overhead Railway, or the locomotives of the South London Railway. Another difference distinguishing this locomotive from the large one designed by the General Electric Company for the Baltimore and Ohio Railroad is that the system is a unit, the motors all forming part of a single system having a rigid wheel base of 15ft., and coupled together by quarter-cranked connecting-rods instead of having two or more bogie trucks with independent, spring-supported motors.

Among the considerations that led to this design, however, were the simplicity and directness of application, the impossibility of operating two or more motors in series satisfactorily on a slippery track when the full tractive effort is required of them without a mechanical coupling, and the likelihood that with large drivers, each flexibly connected to the system, the troubles anticipated from rail impact would not be as serious as had been commonly supposed. The motors are of the "Continental" iron-clad type, the field magnets being formed of two steel castings, and having two field coils placed at the ends of the motors with their planes vertical, thus forming two consequent and two salient poles. The magnets are compound wound, the shunt field being light and only sufficient to keep the speed within reasonable limits at light loads and for returning current to the line, by acting as in a generator, when running downhill. The armatures are of the slotted type, the slots having curved bottoms and tops and contracted gaps. Each slot carries four wires, but there is only one turn of wire to each bar of the commutator, and the wires are threaded through tubes embedded in the slots. The winding is of the two-path type, giving the current only two paths in the armature. The dimensions of the latter are: diameter 31in., length of active part 21in., number of armature coils 237. The height of the steel casting over all is 46in., and the clearance from the top of the rail 5in. The induction in the teeth of the armature is very high, reaching as much as 22,000 C.G.S. lines.

The motors are wound for 800 volts at 225 revolutions, thus being the equivalent of 35 miles an hour when running in parallel. They will safely carry 250 amperes, thereby giving each motor at that speed an output of some 250 h.p., with an efficiency of 93 per cent. On emergency they might even stand more than this. A drawbar pull of 30,000lb. is readily exerted at a speed of 12 miles an hour, and a system of regulation is provided to give any speed from zero up to 35 miles an hour under the full normal tractive effort. The method of regulating is of the series-parallel type, a resistance being thrown in, then cut out, then again thrown in while changing the combinations of motors. The latter may be grouped, first, all in series, with or without the variable resistance; next, two in parallel by two in series; then all four in parallel, with a similar use of resistances at each change. All the motors are operated together, none, that is, being entirely cut out of circuit. These various changes are effected by means of a large contact cylinder, on which the three main combinations are made, and a fireproof resistance frame with the contact arm geared suitably with the main cylinder.

This controlling system can, of course, be moved by hand, though somewhat slowly, because of its massive nature. To effect more speedy changes, power is employed in the shape of compressed air from the Westinghouse brake air-reservoirs, automatically kept at a constant pressure by a special electric pump. In order to avoid any necessity for the driver's attention to be distracted from signals, etc., on the line, or other objects outside the cab necessary for him to watch (as might be the case if he had to turn one handle after another in operating), the controlling air valve is mounted on a small lever so geared as to move backwards and forwards with the main regulating cylinder. His hand is thus carried along with the cylinder; he knows the exact position of the latter by touch, and can use his eyes for watching outside affairs.

A reversing switch is provided, but is automatically locked, except in the "off" position of the main cylinder. Other accessories—measuring instruments, etc.—are also at hand for use as required, all of them in the cab in front of the driver.

The total weight of the locomotive mounts up to nearly 60 tons; and it is therefore by much the most powerful engine as yet actually constructed. For the details and illustrations we are indebted to the *Railroad Gazette* of New York.

In any attempt to criticise the general design of this engine, it is sufficient now to take one point only; the minor details (as might be expected from those responsible for the plan and execution) are well thought out, and will doubtless require little change. The main point at issue is rather one of an economical nature. Instead of aiming at high speed and light loads, the designers have gone to the other extreme, and endeavour to employ electric traction for heavy goods traffic, where low speeds and high tractive efforts are required. Of course this can be done quite easily (and the mere fact is enough to show the extraordinary elasticity of electric traction), but we doubt at present whether the economical results will be so good in the one case as in the other. Probably the experiments to be carried out with the locomotive under notice will help very materially to clear up this point; if so, the workers in electric traction will owe a considerable debt of gratitude to pioneers such as come forward "across the water."

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE III.

Transmission of Power by Wire-Rope Cable.

The origin of the system of telodynamic transmission is interesting. In 1850 there were some large factories at Logelbach, near Colmar in Alsace which had been standing idle since 1841. It was a question of starting these again as factories for weaving. But there was only one steam engine, and the buildings were scattered at considerable distances.† It occurred to M. C. F. Hirn to drive one of the factories at a distance of 80 metres from the steam engine by a steel band, used like an ordinary machine belt, on wood pulleys two metres in diameter, and making 120 revolutions per minute. The steel band was about 2¼in. wide and $\frac{1}{24}$in. thick. This band was used for 18 months, transmitting 12 h.p. Then an English engineer, Mr. Tregoning, suggested the use of a wire-rope cable. A cable of ½in. in diameter was procured from Messrs. Newall and Co., and replaced the steel band in 1852. The same pulleys were used with a groove turned in the rim ½in. deep. That cable worked for years, the pulleys, however, being replaced by iron pulleys. A second transmission, to a distance of 240 metres, was soon erected, with pulleys 10ft. in diameter, with a cable ½in. diameter, running at a speed of about 30ft. per second and transmitting 40 h.p. Supporting pulleys were used at the half distance. These transmissions are still working.

M. Hirn has confessed that his chief difficulty at first was the construction of the pulleys. It was not till he adopted a pulley with a dovetailed groove filled with guttapercha, that he felt the problem of telodynamic transmission to be solved. With these pulleys neither the pulley nor the cable suffered excessive wear.

The amount of work transmitted by a cable is proportional to the product of the effective tension in the cable and its speed. To transmit power to great distances by manageable cables the strongest material must be used for the cables, and they must be run at the highest practicable speed. The cables were at first of iron, now they are generally of steel. The largest cable which it appears to be practicable to use are about 1in. in diameter. In order that the bending stress may not be excessive the pulleys are of large diameter, 12ft. to 15ft. usually. For the throat of the

* The total distance of transmission at Fribourg is 6,500ft.

pulley, on which the rope runs, guttapercha, soft wood, and leather have been used. At present the bottom of the pulley groove is usually formed of strips of waste leather forced into a dovetailed groove. The greatest speed of rope practicable to adopt is that at which the centrifugal tension of the pulley rims becomes dangerous; 100ft. per second has been adopted as the greatest practicable speed. The pulleys are placed at maximum distances of 300ft. to 500ft. apart. The weight of the rope then ensures sufficient adhesion to prevent slipping, when the ropes are tightened so that the deflection or sag is not inconvenient. With these limitations, a 1in. rope will transmit about 330 h.p. In 1854, M. Henri Schlumberger transmitted the power of a turbine a distance of 80 metres to drive agricultural machinery. In 1862, M. Hirn stated that he knew of more than 400 cases of wire rope transmission. In 10 years, M. Stein, of Mulhouse, is stated to have constructed more than 400 telodynamic transmissions, carrying an aggregate of 4,200 h.p. an aggregate distance of 72,000 metres. It may be mentioned here that the largest telodynamic transmissions have been constructed by Messrs. Rieter Bros., of Winterthur.

General Description of the System of Transmission by Wire-Rope Cable.—The cables used are stranded ropes having six to twelve wires in each strand, and six to ten strands in each rope, Fig. 13. The strands are twisted on a hemp core, and usually there is a hemp core to each strand. The hemp makes the ropes flexible. At first, Swedish charcoal iron was used; now the ropes are more commonly of steel. They are protected from oxidation by a coating of boiled oil. It is necessary to keep a spare rope in reserve, in case of accident.

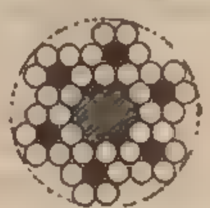

FIG. 13.

The ratio of the tensions in the tight and slack sides is about 2 to 1. In passing round the pulleys the rope is bent, and the bending stress is added to the longitudinal stress. In order that the bending stress may not be excessive, large pulleys must be used. Their diameter is so chosen that the bending stress and longitudinal stress are about equal. As the tension in the slack side is less than that in the tight side, supporting pulleys for the slack side may be smaller than the driving pulleys. The accompanying table gives data of the most extensive cable transmissions.

The stretching of the rope when first erected has given rise to some trouble. The hemp cores are compressed, and the rope diminishes in diameter and stretches. Then it requires resplicing, a troublesome operation. To diminish the difficulty thus caused, Messrs. Rieter Bros. pass the ropes before use between grooved compressing rollers. In 10 to 15 passages of the rope it stretches from 1 to 4 per cent. in length, and its diameter diminishes about 6 per cent.

The piers supporting the pulleys being expensive, and the pulleys themselves being a cause of waste of power, it is desirable that in a wire rope transmission the spans should be large. Spans of 300ft. to 500ft. have been commonly adopted. On such spans the deflection of the rope is considerable, and must be provided for by making the pulley piers high enough to keep the cable off the ground. The deflection of the slack side of the rope is greatest, and hence very often the slack side is placed above the tight side.

Arrangement of Spans.—Fig. 14 (I.) shows an ordinary single span with the deflections of the tight and slack sides of the rope. If the deflection is inconveniently great, it may be diminished by an intermediate supporting pulley Fig. 14 (II.). When the distance of transmission is too great for one span a single endless rope may still be used with intermediate supporting pulleys. In some cases it is convenient to have more supporting pulleys for the slack than for the tight side of the rope. At Frankfort, Ziegler constructed the spans with independent ropes. Then the pulleys at intermediate stations must be double grooved. This is the arrangement generally adopted by Messrs. Rieter Bros., of Winterthur. Prof. Reuleaux has proposed the arrangement in Fig. 14 (V.) to reduce the height of the supporting piers. The spans of the slack side of the rope are half those of the tight side, so that the deflections are nearly equal.

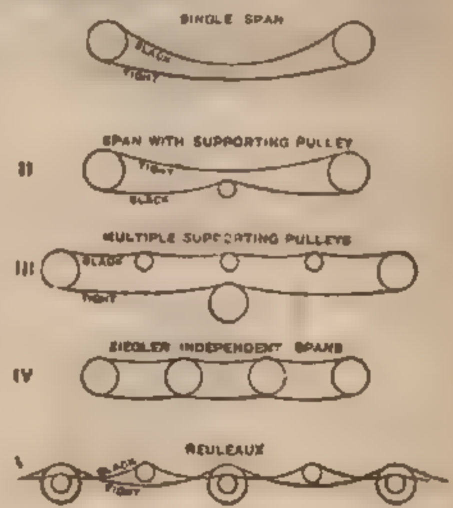

FIG. 14.

In order to give the wire rope a greater frictional hold on the pulleys, and also to increase its durability, the pulleys have wide V-grooves, bottomed with some softer substance than iron, Fig. 15. At first Hirn used guttapercha pressed into a dovetailed groove; then pinewood strips were used; now, almost universally, strips of leather are pressed into a groove in the pulley edgeways. The pulleys are of cast iron, or of cast iron with wrought-iron arms.

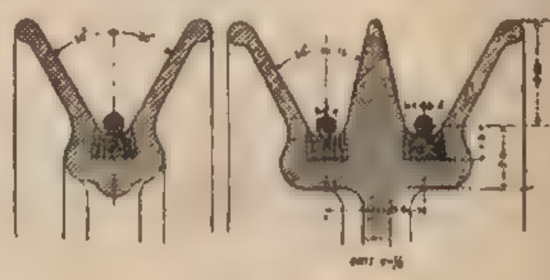

FIG. 15.

As the principal part of the waste of work is due to the weight of the pulleys, they should be made as light as possible. The leather packing in the groove requires renewal every three or four months, and involves a not inconsiderable cost of maintenance. The pulley stations are necessarily costly, being lofty, and requiring to be substantially constructed. They are of timber, of iron, or of masonry. Change of direction of the rope has hitherto invariably been effected by bevel gearing. Fig. 16 shows one of the masonry piers of the Bellegarde transmission. Fig. 17 is a change station, where the direction of the ropes is changed. Reuleaux has proposed changing the direction by guide pulleys, Fig. 18, which would doubtless waste less work.

Efficiency of Rope Transmission.—The two principal sources of loss of work in telodynamic transmission are the friction of the journals supporting the pulleys and the resistance due to the stiffness of the rope. Ziegler's experiments at Ober Ursel gave for the friction of the journals at one pulley station 1·14 h.p., and for the work expended in bending the rope 0·625 h.p., a total of 1·765 h.p. at each pulley station. When transmitting full power, the efficiency of the system is remarkably high. No other mode of transmission to moderate distances involves so little loss of work except electrical transmission. If from Ziegler's experiments the efficiency of each span is taken at 0·962, then for a transmission

of m intermediate stations, or $m + 2$ stations altogether, the efficiency is $\eta = 0{\cdot}962^{\frac{m+2}{2}}$.

Number of stations ($m + 2$) . .	2	3	4	5	6	7
Efficiency.	0·96	·94	·93	·91	·89	·87

This, however, gives the full load efficiency; with diminished load the loss remains nearly constant, and the efficiency is less.

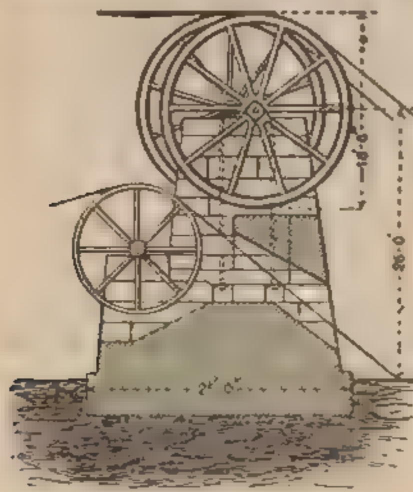

FIG. 16.

The Ober-Ursel Transmission.—Not long after the invention of Hirn's system of wire-rope transmission and its application at Logelbach, an opportunity occurred for trying it on a more considerable scale. A cotton mill had been built at Ober Ursel, near Frankfort, to utilise the water power of the Urselbach. Two

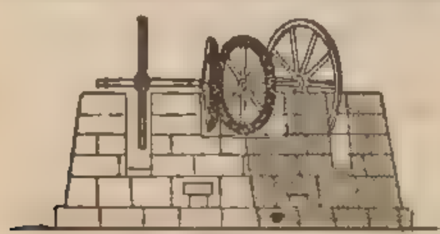

FIG. 17.

tangential wheels were erected on a fall of 165ft. Their total power varied from 64 h.p. to 150 h.p., according to the condition of the stream. In 1860 more power was required. A fall was found above the mill of 264ft., but at a distance such that it could not have been made available by ordinary means of transmission. On this fall two tangential wheels were erected, each yielding from 40 h.p. to 104 h.p. according to the condition of

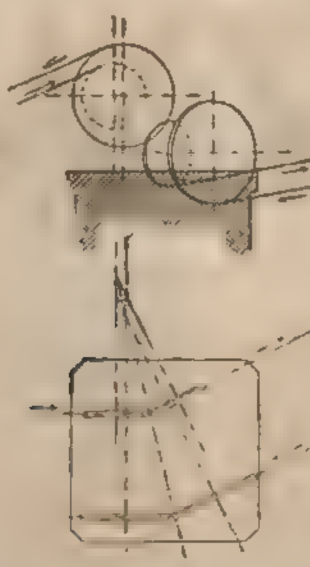

FIG. 18.

the stream. The water from the upper turbines afterwards drives the lower turbines. From the upper turbines the power is transmitted by wire rope cable a distance of 3,160ft., in seven spans of about 400ft. The pulleys are $12\frac{1}{2}$ft. in diameter, and the cable $\frac{3}{4}$in. in diameter. The pulley grooves were lined with leather strips driven edgeways into a groove, a plan now commonly adopted. The pulleys run at $114\frac{1}{2}$ revolutions per minute, and the rope speed is 73ft. per second. The pulleys on the intermediate piers are double grooved, a separate cable being used on each span. Perhaps this was the first completely successful application of telodynamic transmission on a large scale. The work was carried out by Messrs. J. J. Rieter, of Winterthur.

The Ochta Installation.—In 1864, after a serious explosion, the gunpowder factory at Ochta, near St. Petersburg, was reconstructed, and wire-rope transmission was adopted, in order to secure the condition that the dangerous buildings should be at a distance from each other. The motive power of the new factory was supplied by two turbines of 140 h.p. each. A reserve turbine was also erected. The buildings were erected in three lines, one in line with the principal axis of the turbine house, one parallel to, and 420ft. behind, the former; a third at right angles to the first in line with the shorter axis of the turbine house. In each line the buildings nearest the turbine house were 330ft. from it. In the first line there were eight buildings requiring 100 h.p., and the buildings were 164ft. apart, centre to centre. The second line contained 12 buildings placed 230ft. to 330ft. apart, and requiring 80 h.p. The third line contained three buildings, requiring 24 h.p., and placed about 300ft. apart. There were, therefore, 23 buildings, widely scattered, to be supplied with power. The greatest lengths of transmission are 1,300ft., 2,300ft., and 2,600ft. The power was transmitted by wire-rope cables, the work being carried out by M. Stein, of Mulhouse.

The Schaffhausen Transmission.—A still more considerable application of telodynamic transmission, which attracted general attention, was made soon after at Schaffhausen.* After a period of trade depression there was a revival of industry at Schaffhausen between 1840 and 1850. In the year 1850 Herr Heinrich Moser, of Charlottenfels, constructed a canal, and erected the first turbine at Schaffhausen. It then occurred to him that it might be possible to render useful the immense volume of water passing down the rapids of the Rhine in front of the town. An extraordinary low condition of the river in the winter 1857-8 favoured an examination of the bed of the river, and a commission was appointed to mature a project. This commission suggested the formation of a weir across the river, the construction of a power-house on the right bank, with turbines of 500 h.p., on a fall of 4ft. to 6ft., and the transmission of the power across the river to the factories by the then new system of telodynamic transmission. The cost was estimated at £20,000.

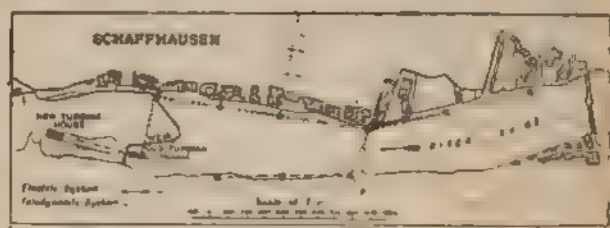

FIG. 19.

Fig. 19 shows the general arrangement of the works at Schaffhausen, with the old turbine-house for the cable transmission, and the new power house for electric transmission, which will be described later.

(To be continued.)

ON THE ARTIFICIAL LIGHTING OF WORKSHOPS.†

BY BENJAMIN A. DOBSON, OF BOLTON.

In manufacturing districts the use of artificial light is of considerably greater importance for work of all descriptions than it can be elsewhere. Whether the work be fine or coarse, delicate or bold, a better light is needed than for work which does not come under the head of manufacture. In Lancashire the staple industries of engineering, machine-making, spinning, weaving, bleaching, and dyeing, are mainly established in certain centres; and with them is invariably associated in the surrounding district the great coal industry. Although Lancashire coal has a number of excellent qualities, yet it is one that makes the most smoke of any. A large portion of the manufacturing industries, great and small, date from a number of years back, when smoke-consuming and smoke-preventing apparatus had not yet been devised; and many of the factories are working at the present day under pretty much the same conditions as when they started. Hence the atmosphere in all manufacturing towns in Lancashire is heavily charged with unconsumed carbon, producing an excess of cloud and fog, which, while inducing an excess of rain, acts also as a screen against the rays of the sun, and thus does a double injury to the neighbouring agriculturist, the producer of the country's native wealth. A circle of 30 miles radius around Manchester is said to include a larger population than an equal circle around any other place in the world, and within this circle, about 12 miles north-

"Funfundzwanzigster Jahresbericht der Verwaltungsrathes der Wasserwerkgesellschaft in Schaffhausen, 1889." Schaffhausen, 1890.

† Paper read before the Institution of Mechanical Engineers.

west of Manchester, lies Bolton, the town with which the author is best acquainted, where all winds, except the west and north-west, bring the surcharged atmosphere from other manufacturing districts, producing at any season of the year, if the wind happens to be slight, a sky ranging from dull lead to dark brown. For four years in succession it has occurred at the writer's works, that on June 21, the longest day, the gas in every room, amounting to nearly 7,500 jets, has had to be lighted by 11 o'clock in the morning, and has remained lighted until work ceased, and this has occurred also in other towns, and in weather that ought to have secured abundant sunshine. To such an extent does gloom prevail that in clear weather the effect of bright sunlight becomes even distressing to the eyesight, simply from the rarity of the contrast.

Requirements for a Well-lighted Workshop.—Firstly, the light, if artificial, should be sufficiently intense to give the power of clear and natural sight over any portion of the work. For enabling the work to be performed with ease the light should evidently be arranged to produce as nearly as can be the effect of natural sunlight. The light of the sun is diffused by the atmosphere; and unless its entrance is limited in extent, such shadows as it may produce are only natural shadows, so natural that the eye has no difficulty in following detail in any visible part. In this respect, therefore, artificial light should as far as practicable imitate the best natural conditions.

Secondly, the light should be so diffused as to avoid casting shadows, or placing any one portion of the work in too great relief as compared with the general tone of the whole. If the work were being done in front of a window which faced the sun, a certain portion of it would receive an undue amount of light, and give a false idea alike of size and distance, owing to the contrast of the overlighted and underlighted parts. This might be a natural light, but would nevertheless be improper.

Thirdly, the light should be of such a character as to have no tendency to injure the sight by a blinding glare. This remark applies either to a good gas flame or to the electric incandescent lamp, from both of which the light is fairly well diffused. The rays being all comparatively weak are easily diverted, and thus distributed. But the effect of having either a bright gas flame or the still brighter coil of glowing wire before the eyes is exceedingly fatiguing and destructive to the sight, and in combination with the dust of workshops makes it a wonder that ocular diseases are not more common than they are.

Fourthly, the light should be of such a character as to leave the atmosphere free from noxious emanations. Any kind of natural or electric light will fulfil this condition. The artificial light that most infringes it is gas, which varies much from town to town, and even in the same town from time to time; but it is generally so impure as to be deleterious to health and comfort in the products of its combustion, which is always more or less incomplete.

Fifthly, the light should not unduly raise the temperature of the room in which it is employed. If on a hot day a gas burner has to be lit for every person in a crowded workshop, as has to be done in certain manufactories, the combustion of so much gas affects the temperature greatly, and thereby produces lassitude among the workpeople, together with various ailments which are almost in proportion to the amount of gas consumed.

Sixthly, the light should be simple, and capable of easy control. The whole arrangement should be so contrived that nothing but the simplest knowledge and experience are required for turning the light on and off. This implies, of course, both a central control and also various points of sub-central control.

Seventhly, the cost should be kept within such limits as will render the light practicable at the present day for those who have to make their livelihood in their special trade in open competition with the rest of the world.

Electric Lighting by Inverted Arc Lamps.—Some years ago, while engaged in visiting and examining certain mills on the Continent, the writer was much struck with a mode of lighting which he then saw for the first time. This consisted in the use of electric arc lamps of from 1,600 c.p. to 2,000 c.p., suspended in a white enamelled reflector at a certain distance below the whitewashed ceiling of the mill. The first he saw was of 2,000 c.p., and thoroughly lighted a large room of about 40ft. square with light sufficient to see to pick up a pin off the floor. The walls of the room, as well as the ceiling, were whitewashed. The light had a sort of bluish tinge, and looked like bright moonlight, but with much greater illumination and entirely without shadows. This appeared so striking that he made a few experiments at once, and found that it was possible to see into the interior of the machines and even underneath them in a way that up to then would have seemed incredible; and, further, that it was not possible to make a shadow of any description, even when holding a hat only 2in. above the floor; all that could be seen in the centre of the covered part was a comparatively slight deepening of the shade. In other departments of the factory he found the same plan equally effective, and the diffusion of light so complete as to be astonishing.

Incandescent Glow Lamps.—At that time the author's firm were engaged in replacing gas by incandescent glow lamps on the Edison Swan system in a large machining-room at their own works, which is 345ft. long by 76ft. broad and only 12ft. high, containing 239 machines tended by 200 workpeople in the area of 26,220 square feet. The exigencies of trade had required that annexes should be constructed almost all round the building, thus further diminishing the amount of natural light that could gain admission. Along the whole of the centre of the shop, for a breadth of some 50ft., gas was burning day and night; and in the close muggy weather of autumn and the fog-laden days of hot summer, the atmosphere of the room became most oppressive, in spite of the best ventilation by Blackman propellers; even at six o'clock in the morning, on entering the room, the smell was most objectionable. It was noticeable too that an undue proportion of the men suffered from diarrhœa, which was, in fact, a standard complaint, and furnished the constant explanation for absence from work. Although sometimes this was simply an excuse, there can be no doubt that the exhalations caused by the imperfect combustion of a gas not absolutely pure will suffice to explain the possibility of a large number of men being affected thereby.

The incandescent glow lamps, each with its own switch, and covered with a wire guard, were attached to the gas brackets, which for this purpose were left just as they had been. Within a week of the application of these lamps the importance of the third requirement, with regard to glare, was amply proved, for nearly every workman had devised a shade of one kind or another, some of white or brown paper, some opaque, and some translucent. No better device than this has been found; it does not look neat, being simply a makeshift, but it answers the purpose, costs nothing, and is applied in a moment. The results of the alteration were curious: the atmosphere was improved, the heat considerably diminished, diarrhœa as a general complaint ceased, and was at first succeeded by bronchitis, which, however, was found to be of a temporary nature, and disappeared as soon as the workpeople in that room had become acclimatised.

Nevertheless, with the result of this lighting the author was not satisfied. The shop was as dark and gloomy as with the previous gas lights. The number of lamps broken by accident and by carelessness was so great as to become a serious consideration, their price being out of proportion to their actual cost, and no allowance being made in regard to royalty in replacing broken lamps which had already paid royalty. The writer then made two further journeys to the Continent, in order again to examine the plan of the inverted arc lamp; and on the first occasion returned more favourably impressed than before. The second journey was, therefore, made with the view of going more thoroughly into the details, and of concluding arrangements for conducting a trial of the plan in his firm's establishment. On this occasion he had the opportunity of examining a large weaving shed at Ruysbroek, near Brussels, on a dark winter night. The dynamo was driven from the main engine of the mill, and was a fine piece of work. Corridors lighted by incandescent lamps led thence to the vast weaving shed, which had the usual roof containing glass panels almost upright facing north, with a plastered ceiling sloping southwards from the top of each glazed panel, and lighted from an inverted arc lamp in each bay between the pillars. The impression upon entering the doorway was that the large room was brilliantly lighted by the mid-day sun: no glare, no flames to be seen, but a golden light pervading the whole of the vast enclosure, the colour of the hair, complexion, and costumes of the workwomen perfectly distinct, under the looms not the slightest trace of shadow. In fact, the result attained was an absolutely perfect ideal light for textile work. The bluish tinge of the arc light itself, when lighting direct, is more apparent than real, because it does not prevent the most delicate shades of colour from being appreciated. If, however, it is considered disagreeable or undesirable, it can be altered as it was in this particular weaving factory, by mixing a trace of yellow with the ordinary whitewash; the ceiling is then still white, but the apparently bluish tinge is eliminated.

The result of this visit was the application of four inverted arc lamps in the large low machining-room at the writer's works. Over 50 tons of castings are daily taken in and out of this room, and there must be at least 300 tons of castings of various sizes and descriptions, in progress of treatment, stacked and piled in different places on the floor. There is, therefore, all the more necessity for good lighting in order to avoid accidents. The darkest portion of the shop was chosen, and the four arc lamps were placed in approximately the best positions for lighting a certain area. The ceiling not being plastered, it was considered advisable to nail up to the joists light scantlings, which were afterwards whitewashed. These lights have now been running almost day and night for about two years, and with unqualified success. The four arc lamps have replaced 26 incandescent lamps; but whereas each incandescent lamp lighted up its own work only and a few inches around, the whole of the area lighted by the four inverted arc lamps is bathed in a gentle temperate light, absolutely equal in all parts. This was encouraging, as an arrangement of this description involves a heavy expenditure, and

it was therefore considered advisable to have further experience before going more largely into it. Moreover, this plan of lighting would not always be applicable. If the ceiling were very low it would scarcely be practicable, because the arc lamp must hang a certain distance below the ceiling and still leave head room. Also there are places where the amount of light required is so small that it would be injudicious to go to the expense of applying these lamps, which are capable of so much more duty. It was determined, however, to make an experiment on a practical scale at the author's works, and with this object to apply inverted arc lamps for the lighting of a three storey building with large attic floor above, the latter being used as an iron and wood pattern-room.

Fire Insurance.—With the object of avoiding any difficulty in the future it would seem advisable, before proceeding with the further development of the plan of inverted arc lighting, to consult the insurance companies in each individual instance. The old style of insurance, where heavy risks were taken by one or two companies only, has now been altered, so that in large works such as those here considered, where the amount of insurance may be near £300,000, the risks are divided among a large number of different companies, who in their turn sub insure their risks in other companies not primarily engaged. There is a tacit understanding between the companies that one surveyor may act for the whole of them in any one particular case, thus judiciously securing uniformity of action. But it unfortunately happened that the four lamps in question, which had been tried for some months at the works of the writer's firm, were lent by them, along with a dynamo and driving power, for the purpose of ascertaining how a certain cotton mill, which had the disadvantage that one corner of the bottom room was darkened by buildings outside, could be lighted so as to replace the missing daylight. The four lamps were placed in position and tested. The result was far beyond expectation. It was found that the cleanliness of the work, which is an essential requirement in cotton spinning, could be supervised to a degree hitherto unattainable by artificial light. The owners of the mill were then anxious to adopt this kind of lamp immediately; but they met with an absolute refusal from the insurance companies to allow any open arc lamp to work in a cotton mill. This led to the question of its further use in the ironworks of the writer's firm, and at first a blank refusal was received, without any reason being given; but correspondence of some months resulted in permission being at length granted to continue its employment under certain rigid conditions. These indeed were reasonable as regards the conducting area of the wires, the voltage, safety fuses, and other necessary precautions.

In order to see whether there could be any valid objection to its use in cotton mills, the author made a fairly complete series of experiments. The danger in cotton mills is supposed to be that the finest fibres or filaments are liable in the process of spinning to escape in a certain proportion, under the action of the draught caused by the moving parts, and being of much the same specific gravity as the air, they are easily carried by upward draught. When they reach any ironwork, either columns, beams, shafting, or gas pipes, they have a tendency, owing to the latent electricity always developed in textile fabrics, to attach themselves radially to the electric or magnetic centre; and as the carding-room air in a cotton mill is always more or less charged with these floating filaments, the insurance companies feared the result of combustion by contact with the open arc would be that the fire would be conducted to a dangerous quarter by the loose filaments adhering to wires, etc. This fear is found to be absolutely groundless. Repeated and extended experiments have in every case failed to show any indication of danger from such a cause. The fallacy of the insurance companies objection is rendered apparent by the fact that at the present time they allow open gas jets in all cotton mills. If there were any danger in an open arc lamp, there would surely be more in open gas jets, which of course are more numerous than arc lamps would be. Furthermore, the arc lamps have to be lowered every eight hours of work for the purpose of changing the carbons. The gas jets are turned off when not required, and lighted again when wanted; this may occur two or three times a day. But every time the electric lamp is lowered it is thoroughly well cleaned, which is especially easy, as it consists simply in wiping the wire and the inside of an enamelled reflector. To prove that the arc lamps cannot convey fire by contact with the cotton fibre, the author has let fall in the inverted reflector quantities of what is termed cotton fly, being the lightest and most inflammable part of cotton fibre; and as soon as the level of the arc was reached and the top fibres were ignited, the fire spread rapidly round the cone of the reflector and burnt downwards towards the bottom. When keeping the eye level with the top of the reflector, it was impossible to see anything escape over this level except the black tinder resulting from the combustion of the fibre or fly. With the true cotton itself, smouldering particles might be seen to the extent of from 4in. to 6in. above this level, but it was proved that these smouldering embers had no heat beyond that necessary to give them their colour, for they were not even capable of exploding gunpowder.

For the purpose of further elucidating the question of fire risk, the author visited a mill in Belgium, not far from Ghent, where very coarse numbers were spun, the cotton being of short fibre, and the amount of evaporation, as it is termed, of fly from the lower filaments was particularly great, the cotton used being of the poorest quality. Directly over the carding engines was an arc lamp of more than 1,200 c.p., and during four hours spent in watching and noting the effect of the lamp upon the fly, on not one single occasion was the slightest spark visible outside the reflector. Sometimes when the fly was unusually thick in the air, owing to a carding engine being brushed out, a slight corruscation could be perceived near the centre of the reflector, like the twinkling of a star, but this would only occur once now and then. Undoubtedly a certain amount of fly was consumed, because when the lamp was lowered for examination a residue was found in the bottom of the cone, composed of the very lightest tinder of cotton, but utterly uninflammable under any circumstances. In this country the insurance companies declined to countenance any experiments, on the ground that mill owners had been satisfied up to that time with the ordinary gaslight and with their insurance regulations, and therefore they could see no good reason for a revolution of ideas. Furthermore, the definite allegation was made that on two occasions fires had been caused in cotton mills abroad which were lighted with arc lamps. Feeling the importance of ascertaining what amount of truth there was in this statement, the author wrote to the proprietor, manager, and others interested in each instance. In the first it transpired that not a cotton mill but a cotton store had been burnt, which was lighted not by arc lamps but by incandescent lamps only, and the theory to account for the conflagration was that of spontaneous combustion, which is by no means rare when cotton is stored in bulk. In the second instance the lighting was not by the open arc lamp inside an inverted conical reflector, but by an ordinary arc lamp surrounded with a glass globe. There was an aperture in the bottom of the lamp, and owing to some disarrangement of the clockwork regulating the carbons, a portion of an incandescent carbon had been split off, and falling through the aperture upon a mass of cotton beneath had set it on fire. When cotton in a loose condition does get on fire it is much like a train of gunpowder, and this mill, which was kept in a condition far from clean, being covered with a thickness of fly steeped in oil over the floor, walls, and ceiling, became so suddenly a mass of flame that the workpeople had considerable difficulty in making their exit from the burning building.

Inverted Arc Lamp.

Arc Lamp.—The complete absence of danger from the arc lamp used by the author will be more thoroughly appreciated from a description of its construction. It consists of two carbons of different diameters, the upper or negative carbon being solid, and the lower or positive carbon being annular and rather larger in diameter. Their areas are 0 200 and 0 486 square inch respectively, which proportion ensures their both consuming at the same speed, thereby avoiding the necessity of any complicated clockwork arrangement to differentiate the speed of the feed. In this lamp indeed there is no clockwork, but the carbons are drawn together by a pulley, string, and counterweight, their distance apart being regulated in the usual way by a magnetic brake. The pulley, weight, and brake are all contained in a cylindrical box attached to the underside of the cone of the reflector; and the only interruption to the light above is that occasioned by the thin arms forming the clip which holds the upper carbon. The crater carbon is here the lower one, in order that the large number of rays produced may be thrown upwards. The cone reflector is 25in. wide at the top and 7in. at the bottom, the angle of the cone being 88deg. The interior surface is ordinary white enamel upon the sheet-iron exterior. Each lamp is balanced by a counterweight over pulleys, and the counterweight hangs conveniently alongside either a wall or a pillar, so that it may not be in the way of traffic. Thus it is easy to lower the lamp for the purpose of renewing spent carbons, which has to be done

about every eight hours, and requires not more than one minute per lamp.

Practical Results of Working.—The plan of inverted arc lighting has now been in use in some portions of the writer's works for 12 and 13 hours a day during the last 12 months, and sometimes almost night and day, and the results of its working he has every reason to believe may be considered successful. The building, as already mentioned, consists of three storeys, each room 123ft. by 55ft.; the bottom room of all is surrounded to such an extent by other buildings that it was necessary to keep the gas burning the whole of the day. In this room the work consists of turning, fluting, polishing, and repairing what are known as fluted bottom rollers for spinning machines. These rollers require to be finished with mathematical accuracy, and the majority of them have to be channelled or fluted to the closeness of from 16 to 19 flutes per inch, the shape of the flutes being of the greatest importance. In the room above are manufactured top rollers to work on the fluted rollers, these also have to be mathematically correct, and their surface finished to a high degree of accuracy. In the third room are manufactured what are known as flyers, having one hollow leg, through which the cotton must pass down in a slightly twisted condition. Owing to the affinity of cotton fibre for metal affected electrically, however little, it is evident that any roughness of the interior surface of the hollow leg must be prejudicial to the working, and it is therefore necessary that the smoothness of finish should be unquestionable. The attic or roof room is used for the storage of patterns, as previously mentioned. In the bottom room there are 51 machines, consisting of lathes and fluting machines and others, and employing 60 workmen. The second room contains 164 machines, employing 139 workmen, and in the third room there are 69 machines and 112 workmen. Views were shown of two of the rooms, showing the position of the lamps that has been found to be most serviceable as the result of experiments. These views give an idea of the area lighted by each lamp, and also of the manner in which the reflected rays from one lamp cross and blend with the rays of the adjoining lamps. The only incandescent lamps used are those in the attic or pattern store, most of which are portable for the purpose of finding patterns on the various shelves; and also, strange though it may seem, two incandescent lamps in the bottom room for the examination and repair of slightly defective flutes. The latter lamps had to be applied because the reflected light from the arc lamps gives no shadow; and, in order to perceive the minute defects in the flute, it is necessary to have a light that will give a prolonged shadow, for the purpose of exaggerating what it is to be seen. The writer quite thought it would be possible to accomplish the same object by the use of a reflector; but the prejudices of the workpeople were too strong.

When first this mode of lighting the rooms was set going, and the gas turned off at the mains, there was much grumbling of the workmen, who protested it was impossible to perform their work by the new light. This difficulty, however, had been foreseen, and they were informed that as the light had been put in at a large expense for their comfort and health, they must at least give it a fair trial. Within six weeks of starting its regular working something occurred which prevented the requisite steam power from being furnished to the dynamo; and the gas therefore to be turned on again, exactly as it had been in the former time. The result was a deputation to the manager on the part of the workmen to know what they were to do, as they could not see how to perform their work by gaslight; and on one or two occasions since then, when the light has failed through one cause or another, the workpeople have declined to work with the gas, stating that they preferred to wait until the electric light was on again, and that they could pull up the time lost.

Dynamo and Lamps.—The dynamo is of Belgian construction, and known as the four-pole dynamo. It runs at 600 revolutions per minute, and gives a voltage of 115. It is driven by a countershaft from the main engine driving the machinery in the building, and with 60 arc lamps and 66 incandescent lamps it absorbs 70 h.p. The lights are steady and free from flicker; if ever a lamp is seen to flicker it may be certainly concluded that it has not been thoroughly cleaned, and that the carbon slides are sticking in the magnetic brake. Photographs are exhibited of each room at 10 o'clock at night in the winter; they were taken, of course, from the reflected light itself, and the exposure was in each case rather less than 10 minutes. Upon examination it will be seen that the detail is wonderfully distinct, even at the distance of 120ft.; this is particularly noticeable in the photograph of the bottom room. Attention must be called to the absence of shadows. It can be seen that there are no dark places on the floor, and that underneath the lathes and other machines, although directly below the reflected light, there is no such thing as a defined shadow.

Horwich Locomotive Works.—Four inverted arc lamps were tried by Mr. John A. F. Aspinall in one of the Lancashire and Yorkshire Railway workshops at Horwich, where, however, owing to the great height at which they had to be fixed, they *were not successful*. They have since been placed in the large drawing offices, and the light for drawing purposes is as perfect a light as can be. Failing on account of the height of the workshop to arrive at a satisfactory result with the solely reflected light, Mr. Aspinall has succeeded in lighting the main machine shop with ordinary open arc lamps, each protruding through a whitewashed disc formed of light boardings framed together. A curious combination is thereby produced of lighting by the reflected and the direct rays. It has not the whole of the advantages of the reflected light, because the eye has a tendency to glance upward towards the dazzling area, and shadows are projected. Nevertheless the writer is convinced that by this combination of reflection a gain has been achieved of at least 25 per cent. over the ordinary direct arc lighting without reflection, and all concerned are satisfied with the result.

Cost.—The question of cost of electric lighting, which after all is of the greatest importance, is somewhat difficult, and the writer is hardly in a position at present to give data sufficient to be of much practical value. Having regard to the number of workpeople who could be served with the light, the cost is less than that of gas, and of course the light is stronger and more general, so that in respect of candle power it would be considerably cheaper than gas. In the three-storey building at the author's works there were 502 gas jets, each burning four cubic feet per hour. Gas costing 2s. 8d. per 1,000 cubic feet would therefore come to something like 5s. 4d. per hour for this consumption. In the 60 electric lamps the only consumption is that of the carbons, which are reckoned at ½d. per lamp per hour. This has subsequently been reduced considerably, but taking this basis, the 60 lamps would together cost 2s. 6d. per hour for carbons. The 66 incandescent lamps which are included in the 70 h.p. absorbed by the dynamo would of course add to this cost, as they are only 1,000 hour lamps. The greatest cost after the original installation is depreciation and horse-power. Taking the whole into consideration, it is probable that the cost of electric lighting would be more than that of gas, but as the light is so much more satisfactory, it may prove an economy in most cases to adopt it. Thus, in the present instance the total candle power of the 500 gas jets would be roughly 8,500, while the arc and incandescent lamps combined would have 73,000 c.p., much of which, however, is of course useless except for the general effect of the light.

Conclusion.—The light now described has proved in practice to fulfil the requirements enumerated at the beginning of this paper as the necessary qualifications of a good artificial light, and for any class of manufacture for which it is applicable. For bleach and dye works, where it is necessary to distinguish minute difference in shades of colour, it must be invaluable, permitting this delicate work to be carried on in the dull winter days, which is now difficult, if not impossible. If the insurance companies can be persuaded that not only is there no danger from this light, but that it is perhaps safer than any other mode of lighting, there seems every possibility that the use of the arc lamp will undergo a rapid development.

BRIGHTON AND HOVE COMPANY.

PROPOSED SCHEME OF RECONSTRUCTION.

The following circular has been issued by the Brighton and Hove Electric Light Company:

In accordance with the suggestions made at the meeting of Debenture-holders' and Creditors' Committee that a scheme for the reconstruction of the company should be formulated, the following is submitted for your consideration and approval:

1. The subscribed capital and liabilities of the present company are as follows:

Ordinary shares of £5 each	£15 005
First mortgage debentures	15,000
Unsecured liabilities (about)	8,500
Total	£38,505

2. The basis of the reconstruction proposed is as follows: (*a*) Present shareholders, £15,005: To submit to the reduction of the present £15 005 ordinary shares to £7,505, entitling the holders to any profits after providing for interest on debentures and dividends on the two proposed classes of preference shares. (*b*) Creditors on unsecured accounts, about £8,500: To be allotted second preference shares to the value of their claim on outstanding accounts, entitling holders to a 6 per cent. dividend after providing interest on debentures and for dividend on first preference shares, and to rank in priority to the ordinary shares as regards capital. (*c*) Debenture holders, £15,000: To surrender half their holding in debenture bonds, viz., £7,500, and to receive in exchange £7,500 in first preference shares, in addition to shares for arrears of interest entitling holders to a dividend at the rate of 6 per cent. per annum after payment of interest on debentures, and to rank in priority to the second preference and ordinary shares as regards capital. (*d*) New subscribers, £5,000: To subscribe £5,000 new capital on prior lien debenture bonds, bearing interest at the rate of 6 per cent. per annum, such prior lien

debentures to rank as a first charge on the property and undertaking of the company in priority to the £7,500 debentures retained by the present debenture bondholders.

3. The following is a statement showing the subscribed capital of the company under the proposed reconstruction scheme:

Ordinary shares—1,501 shares of £5 each	£7,505
First preference shares—8,500 shares of £1 each	8,500
Second preference shares—8,500 shares of £1 each	8,500
Total share capital	£24,505
Debentures—75 debenture bonds of £100 each, £7,500; and 50 prior lien debenture bonds of £100 each, £5 000	12,500
Total share and debenture capital	£37,005

4. Under the above scheme a sum of £5 000 capital is proposed to be raised by prior lien debenture bonds to enable the company to extend its business and to carry out some important alterations to the plant and overhead circuits. The new money will be prudently dealt with and will only be applied to the extension of the business where there is a prospect of a remunerative return.

5. The present debenture holders retain to the extent of one half their present debenture bonds subject to the £5 000 prior lien bonds proposed to be raised. They surrender the remaining one half of their debentures for 6 per cent first preference shares, which shares will be preferential as regards interest and capital so that the debenture-holders under the reconstruction scheme will stand in very much the same position as they do to-day, but will be relieved from the possibility of the present creditors of the company causing a forced realisation.

6. The unsecured creditors in discharge of their debts receive second preference shares entitling them to a 6 per cent dividend after the interest on debentures and dividends on the first preference shares have been paid, and to have priority as regards capital over the ordinary shares, but to rank behind the first preference shares. Debts under £1 to be paid in cash

7. The present ordinary shareholders will submit to a reduction of 50 per cent. of their present holding in the reconstructed company, which shares will be entitled to any surplus profits after payment of interest on debentures and dividends on the proposed two classes of preference shares.

8. By the plan proposed the business will be continued as a going concern. The present company has suffered from too small a capital for so quickly an increasing business, and its present difficulties have therefore necessitated the appointment of a receiver and manager on behalf of the debenture holders for the purpose of protecting the interest of all parties. This has necessarily, for the present, impeded the progress of the business and the obtaining of additional customers; but should the proposed reconstruction be carried out and the company thereby placed on a sound footing, it would be fair to anticipate that the business would be an increasing one. In this view accounts have been laid before the directors by the secretary and manager, and from a careful estimate of the probable revenue and working expenses it is expected that, on the basis of a moderate increase in the output of current, and when the full capacity of the plant is taken up, the net profit should be quite £2 000 a year, whereas the interest charges named above would amount to £750 and the dividends on the preference shares to £1,020, or a total of £1,770

9. The growth of the company's business in the past is shown by the following comparative statements:

STATEMENT OF LAMPS CONNECTED TO MAINS.
(On the basis of 32 watts per 8 c p. lamp)

	1891.	1892.	1893

October	13,769 ,,	18,796 ,,	—
November	16,678 ,,	26,818 ,,	—
December	18,630 ,,	31,652 ,,	

10 It is proposed that the directors of the reconstructed company should, if possible, be elected from local shareholders and debenture holders, so as to give the control of the company to gentlemen resident in Brighton and the immediate neighbourhood, and the formation of the Board is proposed to be constituted of the following directors: By the ordinary shareholders, one; by the first preference shareholders, one; by the second preference shareholders, one; by the debenture-holders, one; by the subscribers of the prior lien bonds, one: total directors, five.

BUSINESS NOTES.

Hull.—Messrs. King and Co. are installing the electric light in the workhouse.

Telephony.—The National Telephone Company are extending operations at Cardiff.

Western and Brazilian Telegraph Company.—The receipts for the week ended October 20 were £3,493.

Bristol.—The Sanitary Authority have resolved to place a refuge and an electric lamp on the west side of St. Augustine's Bridge.

Siemens and Halske Lamps.—Messrs Siemens Bros. and Co. are making preparations to sell Siemens and Halske incandescent lamps at 1s. 6d.

The Guildhall.—The Court of Common Council have resolved to light the Art Gallery of the Guildhall by electricity at a cost of installation of £290.

Change of Address.—The address of Woodhouse and Rawson United, Limited, in Glasgow will be 12, West Campbell-street, after the 11th proximo

Indo-European Telegraph Company.—A half-yearly interim dividend at the rate of 5 per cent. per annum has been declared, payable on November 1.

Glasgow.—Messrs J. Buchanan and Co, Glasgow, have just finished a new brougham built to the design of Sir W. Renny Watson. It is lighted by electricity.

Newcastle.—Messrs Charleton and Co., of Newcastle, have supplied the fittings for the electric lighting of the first-class refreshment-room at the central railway station.

Preston.—The Electric Lighting Committee of the Town Council have held two conferences with representatives of electrical firms on the subject of illuminating the town with electric light.

Chelsea Town Hall Lighting.—The Hall Committee and the Electric Lighting Committee of the Vestry are to again consider and report as to the advisability of lighting the Town Hall with electricity.

Callender's Bitumen Telegraph Company.—The Directors of Callender's Bitumen, Telegraph, and Waterproof Company, Limited, have declared an interim dividend, payable on 1st prox, at the rate of 10s per share.

Gloucester.—The Gloucestershire Standing Joint Committee have adopted agreements for telephonic communication to be established between certain police stations near Bristol and the Bristol telephonic exchange.

Paddington.—The Paddington Baths Commissioners have accepted the tender of Messrs. Dawson and Hammond, of John street, Edgware road, for fixing electric lighting apparatus in front of the platform in the large hall.

The "Hard" Incandescent Lamp.—The "Hard" Incandescence Lamp Company, of Zurich, have appointed as their representatives in this country Messrs Wilhelm and Co, of 132, Wool Exchange, E.C., who will shortly place the lamps on the market.

Dewsbury.—The Local Government Board have written to the Board of Guardians asking for further particulars in respect to the proposal of the Board to expend £2,100 upon the necessary works and plant required for electric lighting purposes.

Monte Video Telephone Company.—The accounts for the year ended July 31 last show an available balance, including £1,879 brought forward, of £8,775. From this amount it is proposed to place £5,000 to reserve, and £3 000 to depreciation fund, carrying forward the balance of £775.

Glasgow.—It is expected that by the middle of November the whole of the Trongate and Argyll street, from Glasgow cross to Anderston cross, will be lit by electricity. In this thoroughfare the lamps are being placed 45 yards apart, as compared with 60 yards in Sauchiehall street.

City and South London Railway Company.—The receipts for the week ending October 22 were £807, against £865 for the same period last year, or a decrease of £58. The total receipts for the second half year of 1893 show an increase of £298 over those for the corresponding period of 1892.

Llandrindod Wells.—At a meeting last week of the Local Board, the clerk read a number of letters containing particulars as to electric lighting, and it was stated that an electrical engineer was willing to attend the Board and explain the system free of cost. It was agreed to hold a special meeting for that purpose.

Personal.—Mr Hylton Spagnoletti has been appointed agent for Messrs. J. B. Saunders and Co, of Cardiff, in Swansea and district for electric light installations and private telephone work. Mr Joseph A. Jeckell, recently works manager of the International Okonite Company, has been appointed electrical engineer to the Town Council of South Shields.

Poplar.—At the meeting of the Board of Works Mr. Cooper, C.E., wrote with reference to the Poplar Electric Act, stating that his clients, the Poplar Electric Lighting Supply Company, were willing to take a transfer of the powers granted to the Board on the usual conditions, with the option of purchasing the undertaking at reasonable notice. This was referred to committee.

Yeadon.—The Local Board have given instructions to the clerk to make application to the Local Government Board for a provisional order for power to light the township by electricity. It was also decided to make application for sanction to borrow £7,000 for such purpose. The "compulsory" area for lighting purposes was decided upon, the extreme ends of the township being left out.

Aberdeen.—The report of the members of the deputation with regard to the Aberdeen Beach will be laid before a meeting of the Links and Parks Committee. The scheme which the deputation recommend involves an expenditure of between £40,000 and £50,000. In addition to a proposed electric tramway suggestions are made for the construction of an esplanade from the Beach Battery.

Newcastle.—The Swan Edison Company have secured premises in this town. The company had the other night some scores of their incandescent lamps illuminated in their windows, several of the lamps were of the fairy coloured kind, and the effect, with the warm glow of coloured windows above, and with the united dazzle of silver and electricity in the large jewellery establishment below, was beautiful.

Hamilton.—The Police Commissioners, as the Local Authority, have held a meeting to consider whether it is advisable to give approval to an application by the Caledonian Electric Supply Company, Limited, to the Board of Trade for a provisional order to authorise them to supply electricity within the municipal boundaries or whether the Local Authority should themselves apply. After consideration the latter course was unanimously adopted.

Tenders for Gateshead.—The Gateshead Industrial Co-operative Society, Limited, invite tenders for a complete installation of the electric light for their Whitehall road branch, Gateshead. Specifications can be had from the secretary on a deposit of one guinea being made, which will be returned on receipt of a *bonâ fide* tender. Sealed tenders to be sent in to the committee, Gateshead Industrial Co-operative Society, Limited, Jackson street, Gateshead, by 4 p.m. on 30th inst.

Meeting of Creditors.—A meeting of the creditors of Wm. Andrews was held last week at Nottingham. The bankrupt is an electrician of the St. Ann's Valley, lately trading and residing at 118, Hungerhill road, Nottingham. Liabilities were stated at £495. 18s. 10d., and the assets at £423. 8s., leaving a deficiency of £72. 10s. 10d. The creditors present were Mr. A. W. West, Mr. W. H. Parker, Mr. Thos. Leman, and Mr. T. F. Walker. The public examination is fixed for November 3.

Wolverhampton.—The gas company's Act, having received the Royal assent, states that additional lands are to be acquired and gasworks erected thereon, subject to the proviso that the company shall not, without the written consent of the Electric Construction Corporation, Limited, manufacture on their present works, or on the selected lands, any chlorine compounds or any sulphuric acid, "except to such an extent (if any) as is produced by or in the manufacture of gas, according to the ordinary methods in use in such manufacture."

Clerkenwell.—At the meeting of the Vestry a letter was received from Mr. E. Garcke, director of the County of London Electric Lighting Company, asking the Vestry to rescind their decision refusing consent to an extension of time for carrying out their order, and stating that they are assured the work would be commenced in January or February next. Mr. J. Walton, in moving that the Vestry adhere to their decision, said they did not say they would not reconsider when their hands were untied. Mr. J. Johnson seconded the resolution, which was carried.

Trade Dispute.—A young man named Albert M'Queen was remanded on Tuesday by Mr. Headlam, the Manchester City stipendiary, on a charge of doing wilful damage. On the 20th inst. workmen were laying down an electric light installation at the Mosley Hotel, Piccadilly. A dispute occurred amongst them, and in the course of it prisoner, who had been discharged, is alleged to have torn away the fuse attached to the Corporation main supply, with the result that the hotel, which had been temporarily lighted up, was thrown in complete darkness. The fuses on the staircases leading from the basement were also severed.

Blackpool.—The electric lighting plant has attracted the attention of several corporations who are considering the advisability of introducing a municipal supply. Messrs. T. Challoner and Son have dissolved partnership with Messrs. Lowcock and Hill in their electrical branch, and are now on their own account supplying all necessary electrical apparatus, and fitting up installations, etc. The firm fitted up the electric light in the Clifton Hotel dining-room in six hours, under the personal supervision of Mr. W. Challoner. The same firm have orders from Mr. W. C. Richardson, Central Beach; Mr. H. Bentley, Church street; Mr. J. S. Todd, Talbot-square, and several others.

Bradford.—The annual abstract of accounts of the Bradford Corporation for the year ended March 31, 1893, has just been issued by the borough accountant (Mr. G. A. Thorpe). In the electricity department the income from this source was £8,399, and the expenditure £3,913. This shows a profit on trading account of £4,486. Against this is set sinking fund and interest charges, amounting to £2,863, leaving a net profit of £1,623 for the year. Up to the beginning of the past year the working of the department had resulted in a net loss of £351, which deducted from the present year's net profit of £1,623 leaves an amount of £1,289, which may be appropriated as the Council deem advisable.

Leeds.—Writing to a Leeds paper, Mr. W. S. Graff Baker says: "*Referring to your account of a meeting* held in support of Mr. Peter Laycock as a candidate for the north-east ward, held at Burmantofts on Wednesday, the 18th inst., I see it reported that Mr. Laycock, in addressing the meeting, stated that 'Mr. Graff-Baker got into difficulties; he had the plant on the hire system from Thomson-Houston, and that when demanded the money he could not pay it. The result was that Thomson-Houston could claim the tramcars and everything in connection with Mr. Graff-Baker's estate.' As this statement is absolutely false, and calculated to reflect upon my credit, I must ask you to give publicity to this letter. I have instructed my solicitor to write to Mr. Laycock, and secure from him a public apology for such utterance."

Tenders Wanted for Derby.—Tenders are invited for the wiring, provision, and fixing of the electric light fittings, the alterations to existing gas fittings where required, and the accessories of the whole or any of these for the electric lighting of the institution for the Chairman and Board of Management of the Midland Deaf and Dumb Institution, Friar gate, Derby. Copy of the specification and forms of tender may be obtained from Messrs. Bramwell and Harris, engineers, 5, Great George street, Westminster, S.W., or from Mr. J. E. Stewart, resident engineer, at the Corporation Electric Lighting Station, Silk Mill lane, Derby, on deposit of two guineas, which will be returned on receipt of a *bonâ fide* tender. Tenders to be addressed to the chairman of the Board of Management, and delivered at the institution by November 6.

Bath.—At a meeting of the Surveying Committee a letter was read from Mr. John Stone (town clerk) stating that he had been instructed by the Watch Committee to complain of the electric light being switched off too early in the morning. Mr. Moore said that the time table of lighting which it was recently decided to adopt on trial was manifestly wrong, as the light was switched on too early, when it was light, and off too early in the morning, when it was dark. Mr. Sturgess had undertaken to see the manager of the company upon the point. The question was referred to the Lighting Committee. Subsequently the usual report was read respecting the electric light, which contained reference to an unusual mention of instances of defective lighting. Mr. Mitchell said it was about the worst record they had had. Bills amounting to £1,553 were passed. This included the quarter's electric light account, from which £8. 15s. had been deducted as fees.

Tenders Wanted for Sunderland.—The Corporation invite tenders for carrying out the work comprised in any or all of the following contracts: (1) Lancashire boilers. (2) High speed compound engines, dynamos, pumps, steam and other pipes, etc. (3) Motor alternators, switchboard, etc. (4) Main switchboard, instruments, and connections. (5) Batteries. (6) Insulated cables, etc. (7) Roadwork (*a*) construction of culverts, laying of cast-iron pipes and casings, and building service boxes; (*b*) supply of cast-iron pipes, casings, and service box frames and covers; (*c*) supply of stoneware casings and insulators. (8) Copper strip. (9) Gunmetal grip boxes. Those desirous of tendering for any of the above contracts must send in their names and addresses to the borough engineer, Town Hall, Sunderland, and copies of drawings, specification, and form of tender will be forwarded to them on receipt of cheque or order for £2. 2s., which will, however, be returned on their submitting a *bonâ fide* tender.

Edinburgh.—At a meeting of the Cleaning and Lighting Committee, the proposed lighting of the chief streets by electricity was under discussion. It appears that the matter had to be taken up somewhat hurriedly, and a recommendation arrived at, as the Board of Trade require to be informed forthwith of the intentions of the Corporation in regard to street-lighting before they give sanction to the general scheme. It was accordingly resolved to recommend to the Town Council that various streets should be lighted by electricity. The lights will be arc lamps. It was stated that each electric lamp in London cost £27 a year, but it was hoped that the Edinburgh lighting would be effected at a less cost. The Electric Lighting Committee of the Town Council have resolved to take power to shut up St. Cuthbert's-lane in that part formed by the triangle of St. Cuthbert's-lane, Dewar-place, and Torphichen-street. This step is necessitated by the contemplated electric lighting depôt.

Whitehaven.—The Whitehaven Trustees have decided to extend the area of supply of electricity for private lighting by laying a cable from the junction of Lowther street and Scotch-street, along Scotch street, Irish street, James street, Swingpump-lane, and Quay street. The private connections so far number about 30, and the Trustees have in hand several other applications, including those of Mr. T. Bowman and Messrs. Pattinson and Winter. Mr. Bowman's branch shop in Lowther street is already lighted by electricity, and the fact that he is desirous of having his extensive premises in the Market place also fitted up with the necessary apparatus for electric lighting says something for the success of the new system of illumination. Messrs. Pattinson and Winter intend having their flour mill at the old barracks lighted by electricity. The lighting of the harbour by electricity is expected to be completed shortly. Already the south side and the north wall are lit up with the new illuminant, and the remaining portions will be similarly lighted as soon as the fittings arrive for the larger lamps.

Eastern Extension, Australasia, and China Telegraph Company.—The report for the half year ended June 30 says the gross receipts, including Government subsidies, amounted during that period to £257,986. 13s. 5d., against £246,988. 16s. 6d. for the corresponding half year of 1892. The working expenses, including £21,649. 3s. 3d., for cost of repairs to cables and expenses of ships, absorb £78,229. 19s. 3d., against £79,281. 11s. 10d. for the corresponding period of 1892, leaving a balance of £179,756. 14s. 2d.

From this is deducted £3,968. 15s. 5d. for income tax, £32,171. 1s. 1d. for interest on debentures, contribution to sinking fund, and special expenditure, leaving £143,616 17s. 8d. as the net profit for the half year. Two quarterly interim dividends of 1¼ per cent. each, amounting to £62,500, have been paid for the half-year under review, leaving £81,116 17s 8d. to be carried forward. The working of the Australian tariff arrangement for the second year of guarantee, ended April 30 last, has resulted in a loss of £43,558, as compared with £55,040 for the first year, and, in accordance with the terms of the agreement, one half of the loss, or £21,779, has been made up by the guaranteeing colonies and the other half borne by the associated companies.

Tenders for Newport (Mon.).—The Electric Lighting Sub-Committee of the Corporation of Newport invite tenders for the supply and erection of steam boilers, feed water heaters, economiser, pumps, mechanical stokers, forced draught apparatus, steam, exhaust, and water pipes, condenser, tanks, steam engines, driving ropes, oil filter, alternators for incandescent lighting, dynamos for arc lighting, switchboards, instruments, arc lamps and lampposts, cables, culverts, surface boxes, junction boxes, converters, converter boxes, converter cases, switches, fuses, meters; also day load plant to consist of semi portable engine, alternator and exciter, and switchboard for the equipment of the municipal electricity works of the county borough. The plan of buildings, map, and specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. Robert Hammond, M I E E., the consulting engineer to the Corporation, 117, Bishopsgate street, London, E C, on and after the 30th inst, on payment of £2 2s., which sum will be returned on receipt of a *bonâ fide* tender. Tenders (sealed, and marked "Tender for Electric Lighting") must be addressed to Mr. Albert A. Newman, the town clerk, at the Town Hall, and be delivered on or before Monday November 20

Dundee.—The completion of the work of introducing the electric light into the joint premises of Messrs Frain and Son and the Edison Swan Electric Company in Castle street is of special interest in connection with the growing popularity of the new illuminant in Dundee The establishment of a branch depôt in the city under the superintendence of Mr William Frain, jun, is intended to meet the convenience of electrical engineers in the East of Scotland. In the installation which has just been introduced the current is derived from the public supply, and the illumination of the entire establishment is controlled from an Ediswan switchboard The fittings in the Edison Swan Company's room, over a hundred of which can be lit up, comprise almost every conceivable variety, and when the full electric current is turned on the effect is beautiful. The company show electric motors of such powers as half and quarter horse, suitable for driving butchers' mincing machines, sewing machines, etc, also voltmeters and ammeters. The installation in the premises of Messrs Frain and Son includes electroliers in each of the windows, and an artistic arrangement of pendants in the saloon. The work of fitting up the whole installation, it should be added, has been carried out by Messrs Maxwell and Son, King's-road, Dundee.

Halifax.—The minutes of the Gas and Electric Lighting Committee presented at a meeting of the Town Council last week, stated that a letter had been received from Mr T England, solicitor, on behalf of the Halifax Mutual Electric Light and Power Company, offering, in consideration of the Corporation paying them £2,000, to guarantee a supply of the light for 12 months, or, as an alternative offer, that the company would accept £4,000 for their plant, the Corporation taking over the same at once The minutes further stated that a deputation had waited upon the committee from the users of the electric light in the district asking the Corporation to endeavour to come to some arrangement in order that the power for supplying the light may be continued as heretofore. A sub committee, consisting of the Mayor, Aldermen Brook and Patchett, and Mr. Thomas Greenwood, had considered the offers and, acting on their report, the committee decided to reject them. Upon the minutes coming up for confirmation, Alderman Tattersall asked what arrangements were being made towards supplying the electric light to the consumers represented by the deputation. The Mayor said the committee had considered the matter, and had come to the conclusion that they could not use the ratepayers' money in the way indicated. Mr. J. Turner Spencer asked if there was any likelihood of some arrangement being made for continuing the electric light before the date when the supply was to be discontinued The Mayor said he did not for one moment think that the committee could make any arrangement. They could not use the ratepayers' money in that way The minutes were confirmed.

Disposal of House Refuse.—Writing to a Cardiff paper, "S C" says: "At a recent meeting of the Parliamentary Committee Alderman Jacobs very opportunely referred to the subject of the disposal of house refuse. It is admitted that burning is the least costly method of disposing of refuse, even when the heat generated is wasted. But by the adoption of efficient generators (not destructors, please), of which several types are being experimented upon and the interposition of steam boilers between the furnace and the chimney, a large amount of heat may be utilised. Heat is money, as our electrical friends only too well know and as most of us feel, and this process of converting ashbin refuse into mechanical energy may be applied to electrical installations with advantage, for the reason that the demand for the power will be absolutely constant. and the best results from destructor cells, as now designed, can only be attained by regular and uniform working. The by products of our domestic economy need be no longer a costly nuisance, but, on the contrary, a source of relief to our ever-increasing burdens. At Oldham and at Warrington recent experiments have shown that the burning of one ton and a half of house refuse per hour has generated gases of over 2,000deg. of heat, which, in passing through a multitubular boiler, 7ft in diameter and 12ft. long, developed 50 h p. per hour. Experts admitted that by the use of better appliances (larger heating surface and more efficient draught, such as a tall chimney stack (the experiments were made with a steam jet)) a much larger evaporation would be attained, probably equal to 90 h.p. or 100 h p., which works out something like 40lb of refuse per horse-power per hour These figures may not be exact; they are taken from notes culled from reports of proceedings This source of heat energy brings the cost of steam power down to the level of water power, which must mean the opening up of a fine field for the operations of electrical engineers, whose sole obstacle, apparently, to illimitable progress and unbounded utility is the cost of power to supply electrical energy to batteries for electrical motors and for haulage of tram and other vehicles, and for lighting, heating, and cooking, and kindred purposes."

Lighting at Camberwell.—As mentioned in previous issues, Mr. Manville was appointed some time ago by the General Purposes Committee of the Camberwell Vestry to report as to the best means of introducing a supply of electricity into the parish. The report having been presented and read, it was resolved that it should form the basis of a lecture This was delivered at the vestry hall on the 20th inst The lecturer, after dwelling upon the progress of electric lighting throughout the United Kingdom, pointed out that an electricity supply undertaking, so far from meaning an addition to the rates, was likely to prove a source of profit to the ratepayers The capital borrowed on the security of the rates was repayable in a period of not less than 30 years, and so long as the revenue derived from the sale of electricity left sufficient profit after the expenses of maintenance were provided for, both the capital and the interest upon the loan were paid without the smallest charge being made upon the rates, and at the end of a period of 30 years the ratepayers owned a valuable undertaking which had cost them nothing Speaking of profits, the lecturer stated that in the case of Bradford at the end of last half-year the profit was estimated at upwards of £3,000 In St Pancras the result of the first year's working was so satisfactory, and the demand for electricity so great, that they were now engaged in extending their works by the expenditure of another large sum. At the Dublin station erected under Mr Manville's advice at the end of the first half year of working, March 28th this year, a net profit of £862 had been made, being almost sufficient to pay the interest on the loan of £38 000 and the sinking fund, and it was known that at the end of the first year's working there will be a surplus after the interest and the sinking fund for the whole year have been paid, and a further sum of £24,000 had been applied for to extend the works. The utilisation of dust destructors was next adverted to. By this means not only could the dustbin refuse of the Vestry be got rid of, but a reduction of at least 15 per cent could be made in the production of electricity. By means of slides a large number of electricity supply stations were illustrated The room was lit by means of high candle power and various incandescent lamps kindly exhibited by the Edison Swan Company. The system of arc lighting and the use of electric motors were illustrated by means of apparatus lent by Messrs. J. G Statter and Co Various experiments were also shown, and a large and most interesting exhibition of cooking and heating by electricity, including ovens, grillers, kettles, curling-tongs, frypans, radiators, etc., in actual work was shown by the kindness of Messrs. R E Crompton and Co At the close of the lecture it was proposed that Mr Manville be requested to repeat the lecture in a larger hall, so that a larger number of the ratepayers might attend.

Barnet.—With reference to the note given in our last issue, the clerk to the Local Board mentioned at a meeting of the authority last week that he had written to the Electrical Installation Company requesting a representative to attend before the Board, but he had received a telegram to say that they could not attend that night. A representative of the company had, however, come down, and was waiting to see the Board. The Board then decided to see the representative. Mr Cooper, one of the engineers of the Electrical Installation Company, 64, Victoria street, then entered the room. He said some three months back he brought the question of electric lighting before his company, and when he mentioned Barnet they seemed very much disposed to apply for powers to light the district The company understood the Board had obtained a provisional order, and when he came down to view the district he made enquiries and understood that the power to light might be given to some company willing to give a proper scheme They were willing to submit a scheme, but they did not know what were the views of the Board. He thought that the town could be well lighted by the low-tension system, which could be carried out and afford sufficient light in an area comprising three miles from the station. With regard to private lighting, they would give private persons the option of installing the wires at their own cost, or renting the wires from the company, or taking the light at a certain price, including wire and fitting up. It was also thought that some amount of revenue would accrue to the Board, because for every 100 lights a certain amount of money would be devoted to public lighting, which his company thought would be an incentive to private lighting. The price per unit would be 8d. per unit at first, but as the scheme increased the price would be reduced They might be able to supply the light at 7d per unit. The public streets would be lighted with arc lamps of 1,500 c p The street lighting would be in two circuits, and the prices for public lighting would depend upon the difficulties encountered in excavating and other

matters, but he could not say exactly what the price per lamp would be. The company would take the provisional order on the terms and arrangements proposed by the Board. The provisional order was for 42 years with option for the Board to let it on lease at 7, 14, or 21 years. In reply to Mr. Morse Mr Cooper said that not less than £6,000 would be required for preliminary expenses. His company would put a plant down with underground mains twice as large as was required for Barnet. Mr Cooper having retired, Mr Walker moved the following motion, of which he had given notice: "That the Board take steps to light their district with electric light at the expiration of the present gas contract, and to supply private consumers under their provisional order." He said the present mode of lighting was not only bad but costly, and mentioned figures showing that the town had lost during the last 20 years nearly £1,000 a year through the lighting not being in their own hands. He had a petition signed by 50 of the largest consumers of gas, whose gas accounts varied from £20 to £50 per annum, asking the Board to light the district with electric light, and those consumers represented £1,200 a year gas rental. He proposed that the public streets should be lighted by 56 high tension lamps placed 80 yards apart, which would cover the district and give a light of 1,000 nominal candle power, which would give a light four times better than they had at a cost of £400 a year, or, roughly speaking, £100 less than for gas. If a contractor took it in hand it would probably cost £700. The private lighting would be low tension, and if they had 3,000 8 c.p. lights at 7d. per unit that would produce £2,100, or an income of £2,500. The figures would then be as follows: Capital invested, £10,000, interest at 3½ per cent., £350 per annum; repayment of capital and depreciation, £550 per annum; salaries, £230 per annum; coal and renewal of lamps, etc., £1,000 per annum; contingencies, £100 per annum—total expenditure, £2,230; income, £2,500, which, as the Board would see, left a surplus. He had asked the Board to use the order themselves, as they would do it cheaper, but he was content to have the matter referred to a committee. Mr. Clark said he would second the motion, because it was time they had some alteration in lighting matters. Mr Widdicombe said the subject of Mr. Walker's resolution should be referred to a committee, and he would move that it be referred to a committee "To enquire first whether it is desirable to light the town with the electric light; secondly, if so, whether it is desirable that the Board should undertake the work itself; and, thirdly, whether the provisional order should be leased to a company. That the committee consist of Messrs. Walker, Morse, Fison, Schmidt, Clark, and Drayson." Mr Martin Pooley seconded the amendment, which, with the following addition, "That the committee have power to insert advertisements in such papers as may be deemed advisable for offers to take the transfer of the provisional order, and to consider replies and report thereon from time to time," was carried.

PROVISIONAL PATENTS, 1893.

OCTOBER 16.

19378. **Improvements in electrical cooking and heating apparatus.** Gustav Binswanger, 71, Queen Victoria-street, London.

19410. **Improvements in electrical fittings, also applicable to other purposes.** Arthur Firth and George Yate Ashwell, 15, Abbey-street, Greenheys, Manchester. (Complete specification.)

19418. **Improvements in the manufacture of wire ropes, electric, and other cables.** John Thomas Williams and George James May, 12, Basinghall street, London.

19423. **Improved continuous electric current distributing system.** Michael von Dolivo Dobrowolsky and "Allgemeine Elektricitats-Gesellschaft," 47, Lincoln's-inn fields, London. (Complete specification.)

19427. **Improvements in electromotor toys.** Richard Myers, William Berwell, and William Albert Griffiths, 323, High Holborn, London.

OCTOBER 17.

19465. **Improvements in systems of electric distribution.** Charles Arthur Allison, 52, Chancery lane, London. (Cyprien Odilon Mailloux and William S. Barstow, United States.)

19515. **The applicati n of tinsel cord in the manufacture of candle shades, electric light shades, and candle sockets.** Emil Guttentag, 12, Bramfield-road, Wandsworth Common, London.

19529. **Improvements in automatic central telephone switch apparatus.** Franz Nissl, 28, Southampton buildings, Chancery lane, London. (Complete specification.)

19534. **Improvements in and relating to electric light switches and wall plugs.** George Davis, 22, Glasshouse street, Regent street, London. (Complete specification.)

19542. **Improvements in apparatus for the electrolytical decomposition of salt solutions.** Carl Kellner, 46, Lincoln's inn fields, London.

OCTOBER 18.

19599. **An improved shade for oil gas, electric, or other lights.** James Frederick Hoyne and George Robert Stoddart, 52, Chancery-lane, London.

19614. **An improvement in secondary battery plates.** William Jeffery, 39, Beckton road, Barking-road, London.

19625. **Improvements in glass bulbs for electric lamps.** Mildred Williams, 26, Budge-row, Cannon street, London.

OCTOBER 19.

19676. **A new electric arc lamp.** Emmanuel Torrini, 46, Hall-street, London.

19688. **Improvements in safety appliances to be used in connection with electrical decomposing apparatus.** James Charles Richardson, 6, Bream's-buildings, Chancery-lane, London.

OCTOBER 20.

19759. **Improvements in dynamo machines.** Frederick William Lanchester, 18, Southampton buildings, Chancery lane, London.

19765. **Improvements in electric switches.** John Leslie Durward, 323, High Holborn, London.

19784. **Improvements relating to the manufacture of incandescent electric lamps, and in apparatus to be used therefor.** Charles John Peach Robertson, 6, Bream's buildings, Chancery lane, London.

19789. **Improvements in electric railways.** Sydney Pitt, 24, Southampton buildings, Chancery lane, London. (The Universal Electric Company, United States.) (Complete specification.)

19791. **Improvements in or connected with electrolytic cells.** Ferdinand Hurter, Henry Auer, and Edmund Knowles Muspratt, 47, Lincoln's inn fields, London.

19809. **Improvements in carbons for electrodes and other purposes.** Hamilton Young Castner, 55, Chancery lane, London.

OCTOBER 21.

19850. **Improvements in tools applicable for use in putting up electric light fixtures and for other purposes.** Charles Bishop, 6, Lord street, Liverpool.

19851. **Improvements in or appertaining to the hearing and of receiving telephones speaking tubes and the like.** William Phillips Thompson, 6, Lord street, Liverpool. (Partly communicated by George Vaugham Benjamin, United States.)

19857. **An appliance for arresting induced electric currents of high potential.** Walter Claude Johnson and Louis John Steele, 28, Southampton buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1884.

16805. **Electric lamp carbons.** Wynne and Powell. (Second edition.)

1889.

10082. **Electric switches, etc.** Binswanger. (Second edition.)

1890.

19740. **Telegraph receivers.** Higgins. (Second edition.)

1892.

7226. **Electric treatment of metal, etc.** Hoho and Lagrange. (Second edition.)

19248. **Electrical conductors.** Webber and others.

21696. **Electric smelting of aluminous ores, etc.** Willson.

21803. **Electric transformers.** Brown.

22061. **Electric motive power system.** Spence and others.

1893.

NOTES.

Saint-Geoire.—This town, in Isère, comprising 2,000 inhabitants, is to be electrically illuminated.

Fire Alarms.—A correspondent suggests the adoption by the London County Council of improved fire alarms.

"Mechanics."—The first number of a new monthly journal bearing this title will appear with the new year.

Battersea Polytechnic.—Dr. W. E. Sumpner has been appointed head of the electrical department of the Battersea Polytechnic.

Fire.—The "fusion of electric wires" is attributed by the fire brigade as the cause of a fire this week at the Raleigh Club, in Regent-street.

Lighting Mail Cars.—The German postal authorities, as a result of experiments, have resolved to electrically illuminate the postal cars on the railways.

Transmission of Power.—A lecture on this subject has been delivered before the Leeds Association of Engineers by Prof. Goodman, of the Yorkshire College.

Damaging Telephone Wires.—Three months' imprisonment was the sentence meted out to a Glasgow man for cutting down and stealing 4,080ft. of telephone wire.

Croydon.—The County Council have instructed the town clerk to apply for a provisional order authorising the construction of a tramway between North End and South End.

Envermeu.—This small town, containing 1,500 inhabitants, and situated in the Seine Inférieure, is lighted by electricity. Water power is used to produce the electrical energy.

Crystal Palace.—The Gulcher dynamos and lamps which have for some years been used in the lighting of the Palace, have been superseded by Crompton machines and arc lamps.

Bremen.—The municipal electricity works commenced the supply of light on September 30. There are 20,000 lamps now connected to the mains and distributed over 350 installations.

City Telephone Tubes.—A reply has been received by the Commissioners of Sewers from the City of London Electric Lighting Company in regard to the telephone tubes laid down by the latter.

The Junior Engineering Society.—On Friday, the 10th inst., at the Westminster Palace Hotel, at 8 p.m., Mr. John Wolfe Barry, M.Inst.C.E., will deliver his presidential address before this society.

Hydraulic Power.—The supply of hydraulic power to the public by the Corporation will begin on February 1. This will enable water-motors to be used for driving dynamos for electric lighting purposes.

Post Office Secretary.—The Postmaster-General has appointed Mr. Spencer Walpole, Lieutenant-Governor of the Isle of Man, to be secretary of the Post Office in the place of the late Sir Arthur Blackwood.

The Inspection Dodge.—Three months' imprisonment was the award made the other day to a "respectably-dressed young man" for pretending to be an inspector of electric light installations in Westminster.

Telephony in India.—There are now 23 telephone exchanges in India. The type of telephone to be used by the Indian Telegraph Department for public use is the same as that employed in the British Post Office.

The Phonopore.—On Monday, in the telegraphic classroom of the Birmingham Technical School, Mr. Whitehouse, the instructor in telegraphy, gave a lecture on the phonopore invented by Mr. Langdon Davies.

Coal-Cutting Machines.—The attention of coal-owners is, it is said, again being directed to the use of electric coal-cutting machines, and trials on a large scale are reported as being made in some of the coalfields.

Traction in Japan.—There are no less than 11 new railways under consideration in Japan, two of which are electric—one from Kobe to Mitamachi, 17 miles long, and another from Sogo to Ozuma, a little over 11 miles long.

Gas in London.—The inhabitants in various parts of the North of London are complaining of the high charge for gas. Delegates from vestries and local boards are considering the matter. Why not undertake electrical illumination?

The Institution of Electrical Engineers.—The first meeting of the 1893-4 session will take place on Thursday, the 9th inst., when a paper will be read by Prof. George Forbes, F.R.S., on "The Electrical Transmission of Power from Niagara Falls."

Berlin.—A dividend of 8½ per cent. for the past year has been declared by the Berliner Elektricitäts Werke, the company which supplies current to some 160,000 incandescent lamps in Berlin, and also electrical energy for the operation of motors.

The Telephonic Athletic Association.—The inaugural smoking concert of the season will take place this (Friday) evening at The Haunch of Venison, Bell-yard, Temple, E.C. The proceedings will commence at 7.30 prompt, Mr. Dane Sinclair presiding.

Potash.—The United Chemical Works at Leopoldshall are about to commence the production of potash according to an electrolytic method. Similarly, the Allgemeine Elektricitäts Gesellschaft are erecting plant at Bitterfeld, and will compete with the former in the manufacture of potash.

Fire Risks.—The first of a course of six weekly lectures upon "Fire Risks of Electric Lighting" was given at the Manchester Municipal School of Electrical Engineering, by Mr. Haldane Gee, to a large gathering of members of the Insurance Association of Manchester, on Tuesday evening.

Lectures.—Mr. J. Swinburne is announced to give, on the 21st inst., at the Royal Victoria Hall, Waterloo-road, a lecture on "The Mechanics of Street Toys." During the coming session of the Greenock Philosophical Society, Prof. James Blyth will deliver an address on "Recent Ideas on Electricity."

Warning.—The police warn householders and keepers of offices in the City and the metropolis generally of the danger incurred by the admittance of unauthorised persons to roofs and other parts of buildings, on the assumption that they have been ordered to inspect telephone and telegraph wires.

Tell-Tale Indicators.—The Admiralty have directed the dockyard officials at Devonport to so arrange the engine indicators of the "Bonaventure" that they may be readily seen by the officer conducting the ship from either the fore bridge, poop, or conning tower in the same way as the ordinary telegraphs.

Lighting at Kingston.—The principal streets of Kingston-on-Thames were illuminated on Wednesday evening with the electric light for the first time. There are 36 arc lamps in the streets, of 1,000 c.p., and which displace 75 gas lamps. The formal opening is announced to take place to morrow.

Type-Setting by Telegraph.—A system for accomplishing this object is said to have been devised by Mr. Donald Murray, of Sydney. Mr. Murray claims that it is possible by his invention to operate at a distance, over a single telegraph wire, a typewriter, a type-setting machine, a piano, or any other keyboard instrument.

Society of Engineers.—The next ordinary meeting of this society will be held at the Town Hall, Westminster, on Monday, when a paper will be read on "Collieries and Colliery Engineering," by Mr. R. Nelson Boyd, M.Inst.C.E. The annual dinner will take place at the Holborn Restaurant on Wednesday, the 14th December.

The Paris Exhibition.—It is intended at the proposed Paris Exhibition of 1900 to give object-lessons in the manufacturing arts, beginning with the raw materials. The transmission of power by electricity will admit of machines being placed everywhere, and render it easy to show how wheat in the husk is thrashed, winnowed, and ground.

Telephony.—Communication by telephone is about to be established between Scarborough and York, with an exchange at Malton. York and Leeds are already connected by telephone, so that business men spending their holidays at Scarborough will be enabled to communicate direct with the capital of the West Riding and other places.

Electric Tramway for Aberdeen.—As mentioned in our last issue, an electric tramway is suggested to be constructed in this town. It would start from Castle-street and proceed thence by the proposed new carriageway to the sea-beach promenade, and return across Links to Wellington-street, along quay, and up Marischal-street to the starting point.

Lighting at Budapest.—The supply of electric light was commenced on the 14th ult. by the Hungarian Electricity Company, who have adopted the alternating-current system designed by Messrs. Ganz and Co. The plant comprises six boilers and three engines of 600 h.p., and one of 300 h.p., together with corresponding alternators, capable of energising 30,000 16-c.p. lamps.

Agriculture.—It has been suggested, remarks a daily paper, that tramways from town to town and village to village, with sidings at farms, might remedy the present difficulty of high rates charged for carriage by rail. It is submitted that either horses or electromotor cars might be used for the purpose, and by this means a far better supply of all kinds of produce might be poured into the towns.

Institution of Engineers and Shipbuilders.—The first general meeting of the session will be held in the Physical Lecture-hall of the Durham College of Science, Barras Bridge, Newcastle-upon-Tyne, on Tuesday next, at 8 p.m. The president will address the members, and a paper will be read "On a Method of Comparing Steamship Performances, and of Estimating Powers and Speeds of Ships," by Mr. W. Hök.

Electric Parcel Cars.—A Manchester paper states that electrical parcel cars, somewhat resembling in shape the parcel-post vans, will soon be seen in the streets of London. It is estimated that for every mile run by an omnibus of one of the great companies the cost for horse traction is exactly 5d., while the cost of running an electric car would, it is submitted, be as low as 2½d. The accumulators have been made so that they can be charged to last for four hours' work.

Leeds Tramways.—The Highways Committee of the Corporation have made arrangements with the Thomson-Houston Company for the temporary letting to them of the Roundhay tramway line on the same terms as those upon which it was formerly let to Mr. Graff-Baker. The lease is for six months certain, determinable thereafter by a month's notice on either side, this arrangement being made so that the line may be subsequently let along with the general tramway system of the city.

Electric Fittings.—A copy of their catalogue of electrical fittings has been forwarded to us by Messrs. Wm. McGeoch and Co., of 10, Berners-street, W. Among the large variety of fittings and accessories dealt with may be mentioned double-pole switches, sudden-break adjustable contact switches, regulating switches, china cut-outs, ceiling roses, "Unique" and tumbler switches, sockets, globe-holders, hall fittings in polished brass, standards, brackets, etc. The company are contractors to the Admiralty for ship fittings.

Motive Power on Ships.—The battleship "Jauréguiberry" will rank among the most powerful vessels of the French navy. A remarkable feature of the "Jauréguiberry" will be the extensive use of electricity as a motive power. It will move the turrets, raise the ammunition, and do much other work which in the majority of modern ironclads is done by steam or by pneumatic or hydraulic power; it will also, of course, light the vessel. The ship will contain 550 incandescent lights, and there will be six very powerful Mangin search-lights.

Oil as Fuel.—Experiments are being made at the Thorncliffe Ironworks, in Sheffield, with oil as a substitute for coal for heating boilers, etc. The large boilers, which supply steam to nearly all the machinery near the blast furnaces, are being used for experiments. The oil is placed in a cistern over the firing place, and by means of steam-jets forced under the boilers, where it is ignited, the result being flames of intense heating power sufficient to produce steam of a pressure of 80lb. to 100lb. The results of the experiments are said to be highly satisfactory.

Chicago Exhibition.—This exhibition has now been closed. Messrs. Hoveler and Dieckhaus have been awarded the first prize (medal and diploma) for their tandem bearing metals, the firm being the only one of those having exhibited in the same section who received an award for anti-friction metals. The first prize gold medal has been awarded to the "Victor" turbine made by Mr. F. Noll. We are informed that the medal for the best flue feed-water heaters has been awarded to the Fuel Economiser Company, of Matteawan, N. Y., for the Green fuel economiser.

Exhibition of Industry.—An exhibition of industry will be opened in Lochee-road, Dundee, in December. It is promoted by the Dundee and District United Trades' Council, and is to be on lines similar to the previous one of 1887-88. In addition to exhibits from manufacturing firms, the exhibition will afford an opportunity for the production of inventions, etc. The exhibition will consist of three sections: (1) industrial or domestic work; (2) trades and manufactures; (3) art. In the second section, Class 21 will comprise electrical engineering and appliances, and Class 22, gas engineering and appliances.

Cambridge.—The new science building which has been erected by the governors of the Leys School, Cambridge, was opened on Saturday by Lord Kelvin. The building, which has cost a little over £4,000, contains four laboratories on the ground floor, chambers in the basement for electrical work, three lecture-rooms upstairs, the largest of which has been named the Kelvin Room, and various other rooms for scientific work. The object of the governors in establishing a science department has been to enable the boys to go into the university thoroughly prepared to enter upon a scientific course of education, and well grounded in practical work.

Telephoning Telegrams.—A joint arrangement between the postal authorities and the National Telephone Company will come into operation in Leeds on Monday. The head telegraph office will be connected with the telephone company's exchange in Park-row, and its subscribers, on making a deposit with the company to pay the cost of telegrams, will be able to telephone telegrams for transmission to all parts, instead of handing them in at branch telegraph offices. Inward telegrams for subscribers within the Leeds postal area may for convenience be telephoned on arrival through the National Telephone Company's exchange instead of being delivered by messenger.

The Choice of Meters.—This subject is dealt with by M. G. Claude in *L'Industrie Electrique* of October 25th. The writer concludes that in important installations, where one desires to ascertain the energy consumed with great exactness, and where the meter rent is relatively insignificant, it is advisable to use the energy meter. On the other hand, in the case of small installations the employment of the intensity meter can only be advantageous, and the generalisation of the method adopted at the Vincennes station (which, however, M. Claude does not describe) in this respect could only result favourably from the point of view of the development of small installations.

Can We Do Without Coal ?—This is practically the text of the subject dealt with in an article by M. A. Moutier in *L'Electricien* of October 28, and entitled "The Miners' Strike." The author asks whether coal is the only article from which we can obtain the power we require, and he replies in the negative. As alternatives, he suggests the utilisation of the wind and of water power. There are, he says, two methods of employing electricity produced by these agencies. One is by the transmission of power by electricity by the use of overhead or underground conductors, and the other by the aid of accumulators. He submits that the latter method is to be preferred.

Telegraphic Dictionary.—The International Telegraphic Bureau of Berne is compiling an official vocabulary for telegrams in a language agreed upon for the purpose. The book, on which, amongst others, English, Dutch, and Spanish functionaries have laboured, will comprise at least 240,000 words, selected from the English, German, French, Italian, Spanish, Latin, Portuguese, and Dutch languages. It is said that the composition will be complete by next March, when it will be immediately issued for sale. Not for three years, however, will it be in general use. The International Telegraphic Congress, which will take place at Budapest in 1896, may possibly recommend the Postal Union to adopt it.

Registering Lightning Strokes. — An apparatus intended to register the number of times a lightning conductor has been struck by lightning has been devised by Messrs. Siemens and Halske. A cast-iron box contains the mechanism, which comprises a bar of iron which is magnetised by the current passing along the conductor and caused to deviate against a spring, this displacing a needle on a dial. A screw stop prevents the movable piece from passing beyond a certain limit. The whole of the mechanism is fixed on the cover of the box in such a manner as to be readily accessible, and the sensitiveness is such that a momentary intensity of current of at least 250 amperes is necessary to cause the index to move.

Personal.—Prof. von Helmholtz, who recently returned from a visit to the Chicago Exhibition as the official representative of Germany, was born at Potsdam in 1821. His early discoveries were mostly confined to microscopy and fermentation, though his wide learning soon made itself felt in all branches of science. His great invention was perhaps the ophthalmoscope, the discovery of which, in 1851, caused sensation in the scientific world, and has been the means of saving the eyesight of thousands. In 1871 he took the chair of physics at the University of Berlin, where most of his electrical researches were carried out; and in 1887 he accepted as well the control of the new physico-technical institution in Berlin, which was founded chiefly by the late Dr. Werner von Siemens.

"Machine Drawing."—We have received a copy of "Machine Drawing," a book intended for the use of students in science and technical schools and colleges. The work, the authors of which are Messrs. T. Jones, M.I.M.E., and T. Gilbert Jones, Wh.Sc., comprises 40 plates of machine details, with descriptive letterpress and numerous perspective illustrations. Exercises are given requiring the student to test his power of making original drawings by deducing from the complete views given others which are not contained in the book. For this purpose the descriptive letterpress and notes and exercises provided with each drawing, and the perspective illustrations, will prove of great assistance. The book, which is published by the authors at 27, Barton-street, Moss Side, Manchester, should be of value to the large section of students to whom it appeals.

Lightning Conductors.—A danger incurred in fixing lightning conductors, in the ordinary fashion, to high chimneys is pointed out by a correspondent. Owing to impurities in the coal, gases are given off in the smoke from the fires below, and which are said to oxidise the lightning bar, and so eat completely through the rod, or materially reduce its section. In order to avoid accidents from the above cause, a method has been adopted at some works in Germany of surrounding the metal bar in a system of glass tubes, the space between the glass and metal being filled up by a special kind of cement. The upper end of the highest tube is sealed hermetically, allowing only the platinum point of the bar to project. The glass not being susceptible to chemical action, either from smoke or atmospheric conditions, protects the lightning rod from being eaten through or diminished in section by oxidation.

Electrical Train Staff Working.—From a recent return embodied in the Blue book on "Railway Signal Arrangements and Systems of Working," we learn that out of a total distance of 4,345 miles of single line in England and Wales, 1,020 miles, or nearly one quarter, are operated upon some approved electrical train staff or tablet system, such, for instance, as that devised by Mr. F. W. Webb, chief mechanical engineer of the London and North-Western Railway, in conjunction with Mr. Thompson, the company's signal engineer. The Cambrian leads the van in this direction with 174 miles, the Great Western has 143, the Midland 106, the North-Western 103, and the South-Western 88. In Scotland, out of 1,658 miles of single line, 480 are worked in this way: the Caledonian having as much as 259 miles alone, and the North British 105. The proportion in Ireland is still greater, out of 2,240 miles open for traffic, 995, or nearly half, being worked with electrical train staffs.

The Government and the Telephones.—The London correspondent of a Manchester paper learns that the Postmaster-General may not improbably consent to the appointment of a parliamentary committee to consider and report upon the proposed arrangements between the Post Office and the National Telephone Company, and generally on the future policy of the Government in regard to the extension of the telephone service. The reasons for this change of attitude on the part of the Post Office are said to be the facts that the movement for the municipalisation of the telephones has been gaining in strength, and that the

case for the corporations was not heard before the Select Committee on whose report the policy of the late Government was framed. But there is also understood to be a desire on the part of the postal authorities to consider the question of State acquisition, to which the period that has now been reached in the license of the National Telephone Company had given a present interest and importance.

An Important Electric Railway Trial.—The managers of the Intramural Electric Railway at the Chicago Exhibition having felt that trains much heavier and longer than are ordinarily run could be operated, recently made a trial to prove that this was the fact. Mr. W. E. Baker, manager of the Intramural line, late at night started out a train composed of one live motor car, two still motor cars, and nine empty cars, weighing in all about 196 tons. This heavy train was pulled along, apparently, without effort, even when it turned the loops at either end of the line, each of which has a radius of over 100ft. On the following day, which was Railroad Day, invitations were issued to the railway magnates assembled at the exhibition, and a train of eight cars (one motor car and seven trailers) was provided. The train was loaded to its fullest capacity, no less than 800 persons being carried. The motors ran smoothly at their maximum speed, and the test was satisfactory in every respect. The weight of the train can be conservatively estimated at 212½ tons.

Cardiff Tramways.—In the course of a communication to a Cardiff paper with regard to the municipalisation of the tramways, Mr. W. N. Colam cautions the members of the Corporation against committing themselves to opinions of the best motive power for Cardiff from information they may have gleaned from America. He states that the adoption of a motor for American streets is no guide, but, rather, misleading, as to what could be tolerated in Europe. It is also to be remembered, he remarks, that the spheres of useful work for electricity and cable are quite distinct and separate, and this is evidenced by the fact that the cable system has just been installed and set to work in the two most important streets of the United States—viz., Broadway and Third-avenue, New York—whilst systems of electric haulage are very frequently applied under different conditions of traffic. Mr. Colam suggests that members of the Corporation, individually or collectively, should make enquiries as to the conclusions arrived at on this all-important question by the cities of Edinburgh, Newcastle, Glasgow, Birmingham, and London

A New Method of Suspending Motors.—Among the improvements which the introduction by the General Electric Company of the new "G. E. 800" street-car motor has brought into street-railway practice, is a new method of suspending the motor on the axle and the truck, whereby it is made to rest upon a resilient system, the weight being supported at a point immediately below the centre of gravity of the motor itself. This system of suspension is known as the cradle suspension. Immediately below the armature bearings are trunnions on each side of the motor, set in side bars, which are pivoted at the front to a special casting, and supported at the rear end from link bars bolted to the truck frame. The front special casting is mounted upon six springs, two of which offer resistance to pressure upwards, and form resistance to the downward pressure. It will thus be seen that this modification is of significance in electric railway practice. The motor being set upon a spring-like cushion, the greater part of the dead-weight is taken off the axle itself and is more evenly distributed to the axle bearings and that part of the truck which can better stand the strain. This, in conjunction with the extraordinary lightness of the motor, means economy of track maintenance and a decrease in the possibility of accident to the axles. A series of careful tests have already shown the value of the improvement, which promises to become general where the "G. E. 800" is used.

Electrical Purification of Sewage.—Some interesting sanitary experiments are being carried out at Havre on the Hermite system in connection with the Exhibition of Hygiene. This system is based upon the electrolysis of sea water. The electric current decomposes the chloride of magnesium, whilst the chloride of sodium serves as a conductor. The result is a liquid disinfectant of great power. It is almost odourless, leaves no residuum when used for purposes of flushing, and is perfectly inoffensive. Although sea-water renders the application of this system considerably cheaper, it is not essential to it. When not procurable, a solution of chloride of magnesium can be used instead. At Havre, M. Hermite has found the opportunity for which he has long been waiting. There is sea-water in abundance, and an enterprising municipality. A central station has been constructed, supplied with the necessary electrical plant and convenient tanks, in which the disinfectant is prepared in sufficient quantities. By a simple arrangement of pipes and ducts this is distributed through the streets like water or gas. It can also be laid on to the houses, which, when once supplied with the disinfectant, help to purify the main drain, instead of adding, as is now the case, to the general contamination. Sewage thus treated has been submitted to severe examination, but French bacteriologists are said to have sought in vain for those microscopic forms of life which wage a constant war with the human race. If all that the French sanitary engineers claim for M. Hermite's system be true, great improvement will take place in the health of any town adopting it. It has been applied to the Quartier Saint-François, and those who have seen its effect have been deeply impressed.

Electricity Applied to Irrigation.—An interesting series of experiments in the way of irrigation by sewage is being conducted by Mr. W. S. Freeman, of Otford. The trials are being made on a portion of Boughton Farm, Otford, which has been placed at the disposal of the operator by Mr. Greenlees, and the work has been confined to a hop garden of about eight acres and an adjoining meadow through which the main sewer runs. This is some distance from Mr. Freeman's works, where the electricity is generated by a large waterwheel geared to a Crompton machine capable of working up to 1,250 volts and 15 amperes. From here the current is led by overhead wires to the scene of operations, where a 6½-h.p. motor works a 3in. centrifugal pump having its suction pipe placed into the sewage. Attached to the pump is a series of iron pipes, conveyed on stands at the height of about 20ft. to the upper end of the hop garden. Through this pipe the liquid is conveyed, and delivered into a trench, from which there are tributary trenches running down each alley and diverted on to each hill. The delivery of sewage by this means varies from 3,000 to 5,000 gallons per hour, and it is estimated that each hill receives about 20 gallons of liquid. In this way an area of two acres were covered per day, with the assistance of two labourers only, and at the nominal cost of £1 per acre, or 1¼d. per ton of sewage. Previous to commencing the work the hops to be treated had suffered severely from the drought, the leaves having died off, and the bine being very attenuated. At the present time the plants have a healthy appearance, the bine has been resuscitated, and in place of the decayed "pin" fresh laterals have commenced to shoot strongly, while the leaves are fresh and sturdy. During the last day or two of the experiments the sewage was diverted into channels formed through the meadow above mentioned, and the

benefits likely to accrue are already manifest in the increased succulence and strength of the pasturage.

Magnets and Electric Currents.—The third of the Gilchrist lectures at the Assembly Hall, Mile End-road, was delivered last week by Prof. J. A. Fleming on "Magnets and Electric Currents." The oxy hydrogen lantern was brought into play in throwing picture shadows of the magnets and other apparatus in operation upon the screen. The lecturer started by explaining the natural magnetism of the "loadstone," which is chemically known as magnetic oxide of iron, and showed that it was capable of transferring its magnetic properties to pieces of steel, although not to soft iron. The peculiar properties of a balanced magnetic needle in placing itself north and south were next illustrated, and likewise the system upon which telegraphic messages are sent by the old needle instruments. Any magnetised piece of steel suspended on a pivot and surrounded by a coil of wire would place itself at right angles with the coil so soon and so long as a current of electricity was allowed to pass through the coil. The lecturer demonstrated by experiments the fact that a magnet has a soul as well as a body, and showed by means of iron filings the lines of magnetic force flowing around a magnetised bar. The galvanometer was then introduced as preliminary to an explanation of the meaning of galvanic currents. He had a very sensitive Thomson reflecting galvanometer on the operating-table, arranged to throw a spot of light from the lantern on the screen. This invention, it was explained, was essentially a minute mirror fastened to a delicately-suspended magnetic needle swinging inside a coil of wire, through which electric currents were passed. The principle on which cable messages are sent across the Atlantic was described, it being incidentally stated that the aurora borealis had a curious effect when present in the northern skies of disturbing the swing of the magnetic needle. It was, he said, believed that the aurora were electrical phenomena, and they indicated electrical disturbances in the earth, which was itself a big magnet. Next came the formation of artificial magnets, or electromagnets, by sending powerful electric currents through wire coiled round bars of soft iron. As long as the current continued to flow the iron was strongly magnetic, but this property ceased as soon as the current was stopped. Having thus obtained magnetism from electricity, the lecturer next reversed the process, and obtained electricity from the act of moving a magnet in and out of a coil of wire. This led to the dynamo-electric machines of the present day, a sketch of which was given, and a brief description of the electric light and other modern applications of electricity. In conclusion, portraits of electrical celebrities—the brothers Siemens, Edison, Swan, Kelvin, Clerk-Maxwell, and Faraday—were thrown on the screen.

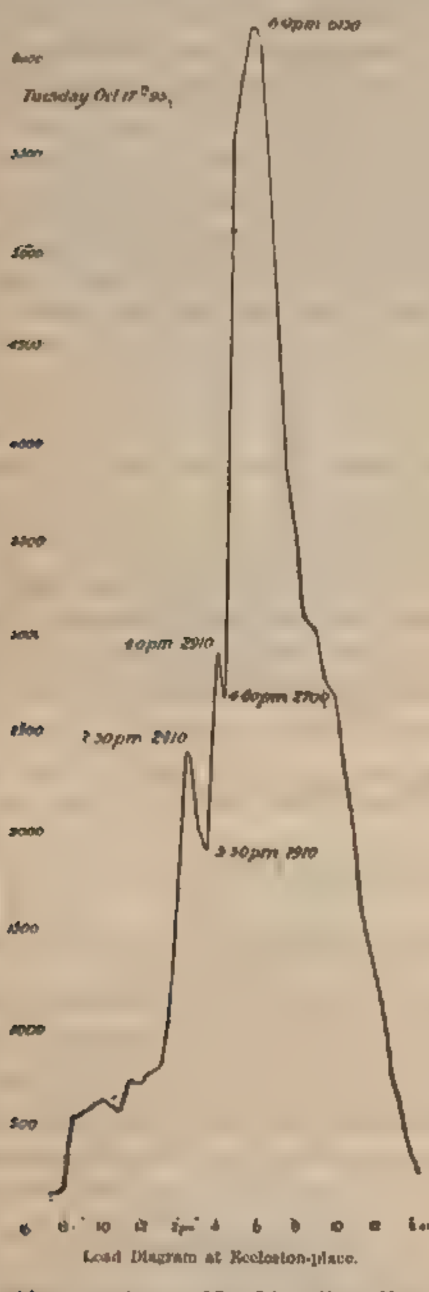
Combined Rotary and Direct Current Station.—The electricity works in Bockenheim, a kind of suburb of Frankfort-on-the-Maine, possess various features of more than ordinary interest. The station was designed to deal with both lighting and motive power, Bockenheim containing many large and small industrial works requiring motive power. A lengthy illustrated description of the station, which was built and equipped by Messrs. Lahmeyer and Co., is given by Mr. F. Uppenborn in the *Elektrotechnische Zeitschrift* of October 27. The station supplies the town with two currents—one is a high tension rotary current, and the other a low-tension continuous current. The E.M.F. of the former, which is used for the operation of motors, is 660 volts; that of the latter has a pressure of 110 volts, and is employed for lighting and for the energising of electromotors of small power, as, for instance, up to 3 h.p. The plant comprises two water-tube boilers by Simonis and Lanz, of Frankfort-on-the-Maine, and constructed for a working pressure of up to 150lb., and provision is made for the laying down of two additional boilers. There are two engines of the horizontal tandem compound condensing type, by Messrs. Pokorny and Wittekind, of Bockenheim, giving 250 h p. when running at 96-100 revolutions, and capable of also working non-condensing. Each engine is coupled direct to a low-tension rotary-current machine, these dynamos having the same arrangement as those of the Brown type used in the Lauffen-Frankfort plant. These machines at 100 revolutions and 80 alternations give 80 volts terminal pressure, and their output amounts to 130 kilowatts, or about 200 h.p. From the flywheels of the engines are driven by belts two Lahmeyer direct-current dynamos yielding 110 to 150 volts at the terminals, and an out-turn each of about 33 kilowatts. These machines serve partly to excite the rotary current dynamos and partly to charge accumulators, and to supply continuous current to the surrounding district. In order to allow both of the continuous-current dynamos to feed into the continuous-current network, and yet to have available the extra pressure necessary in the charging of the accumulators, an auxiliary dynamo has been brought into requisition, this being direct coupled to a rotary-current motor. The continuous-current network is arranged on the two-wire system. Connected on one side of the continuous-current omnibus bars are the two dynamos and the battery of accumulators, and on the other side the feeding mains of the continuous-current network. The battery, by means of a double-cell switch, stands in connection on the one hand with the omnibus bars, and on the other with the dynamos. The battery comprises 64 Tudor cells, having a capacity of 430 ampere-hours. With regard to the rotary-current dynamos, the current is conveyed to the switchboard, and it then passes through three safety fuses and an ammeter, and by means of three switches it reaches the low-tension rotary-current omnibus bars. These dynamos are put in circuit through a voltmeter, voltmeter switch, and a "phase" indicator. The latter consists of three pairs of incandescent lamps in series, which on the one side are connected to the three omnibus bars, and which on the other can be put in connection by a triple switch with the rotary-current machine to be placed in circuit. On the insertion of a rotary-current machine, its tension is at first brought to the same pressure as that of the omnibus bars. Upon this the phase lamps are put into communication with the machine. When this is done, the disturbances due to the alternating lighting up of the three lamps show themselves. The speed of the machine to be put into circuit is then regulated until the disturbances cease and the equal phase is present. This is ascertained by the complete extinguishment of the lamps. If this is attained, the machine can be inserted, and the synchronism of both machines is maintained steadily with a certain power. Three conductors are led from the low-tension omnibus bars to two converters, which transform the current from 80 volts to about 700 volts. From the secondary windings the three conductors pass to a switch, safety fuse, and to the high-tension omnibus bars, which are connected by safety fuses to the feeding mains. In the interior of the town the cables for both direct and rotary current are laid underground. They are of the Felten and Guilleaume iron-armoured lead cable type, those for the rotary current being triple-concentric, and for the continuous current simple cables are used. Outside the town overhead wires are used. The rotary-current unsynchronous motors energised from the network—and of the whole 400 h.p. in the local factories no less than 200 h.p. are supplied from it—are operated *direct* from the high-tension mains.

ELECTRIC SUPPLY COMPANIES.—I.

(Continued from page 374.)

WESTMINSTER ELECTRIC SUPPLY—DAVIES STREET STATION.

The third and largest central electric station of the Westminster Electric Supply Corporation is situated at the top of Davies-street, Berkeley square, W. The station occupies the greater part of a really fine pile of red brick buildings, in the modern Victorian style, dominated by a tall and well-proportioned chimney, from which floats continuously a light cloud of steam, for the engines here exhaust into the air. Sets of chambers and shops occupy the rest of this building, and the station is reached through two gateways with wrought-iron gates, while the engineer's house forms part of the same block.



Load Diagram at Eccleston-place.

The resident engineer, Mr. Llewellyn Foster, is the earliest of those who joined the engineering staff of the Westminster Corporation. The first start of electric supply in Westminster, it will be remembered, was made at Dacre-street, where plant for lighting the block of buildings including Victoria-mansions and the Members-mansions was erected in 1889. The plant there used was supplied by Messrs. Crompton, and Mr. Foster took command, having then just returned from electric pioneering in Australia to devote himself to central-station work in London.

There is not another more interesting station in its line that could occupy the attention of the electrical engineer. Davies-street station is, we can easily imagine, the pride of Prof. Kennedy's heart, and the engineer-in-charge seems to feel the same sentiments. The daily maximum output is now over 6,000 amperes, and the total number of lamps supplied from this station is now (in October, 1893) 63,500 8-c.p. lamps. And still the demand keeps increasing in a degree beyond that even anticipated in this influential district, so that the addition of a new 350-h.p. set of engine and dynamo, which has just been put down, comes none too soon.

The district of supply comprises the fashionable West-end quarter known as Mayfair, and extends along Oxford-street, from the Circus to the Marble Arch, and from Park-lane along Piccadilly as far as Bond-street, then up Old Bond-street and Conduit-street into Regent-street. In Oxford-street it is the south side only that is supplied by the Westminster Corporation, the north side falling within the district of the Metropolitan Company.

The staff at Davies-street is composed as follows: resident engineer, Llewellyn T. Foster; second engineer, H. Howard Baker; third engineer, G. Horley. The working staff comprises 18 men—viz., an engine staff of two switchboard attendants, one battery attendant, two head drivers, two assistant drivers, and two cleaners; and boiler staff including three head stokers, two assistant and two coal-trimmers; the remainder comprise carpenter, store-keeper and clerk.

STATION.—Davies-street station was opened on March 25, 1891, with four engines and dynamos—two 80 h.p. and two 140 h.p., the two 80-h.p. Willans engines with Crompton dynamos being those removed from the Dacre-street station. The building was designed by Mr. Peach, the same architect as for the other Westminster stations, and was built by Messrs. Holliday and Greenwood, of Loughborough-road, Brixton. The supply of current was commenced with 1,500 lamps connected, the engine power being 440 h.p. During the building operations, the plant was run under a wooden shed with a temporary chimney, and, in fact, the premises have only been completely finished last year. There are now 11 engines—six 200 h.p. and one 350 h.p. sets having since been added, making a total of 2,000 h.p.

The engine room is an exceedingly fine one—size, 90ft. long by 47ft. wide, very high and open, and covered with a glass roof. The height gives corresponding coolness and freshness, and the glass roof is of great advantage in gauging the probable weather. When darkness falls the load frequently goes up from 800 amperes to 4,000 amperes in 20 minutes, and in times of snowstorm or shifting fog the load will frequently rise 2,000 amperes or more in five or six minutes; and as the gathering gloom can be seen through the roof by the engine-men, no time is lost in starting engines.

In entering the station one walks straight into the engine-room from the carriageway, down a flight of steps to the engines or up a few steps to the switchboard. A staging is erected at the near end for carts to unload, a 10-ton travelling crane carrying the load to any desired spot. The present line of engines and dynamos occupies the whole of the left side of the engine-room, and the new 400-h.p. engine is placed at the further end to the right. Foundations for a second 400-h.p. engine are already laid, and there is room in all for eight or even nine more such sets to complete this second line of engines.

BOILERS.—The boiler-room is 2ft. lower than the engine-room. Its size is 72ft. by 43ft., and the accumulator-room is above, of the same size, on concrete floor carried on girders.

There are seven boilers—five Davey-Paxman modified marine type boilers (steel boilers 12ft. long by 8ft. diameter), as at Eccleston-place, and two Fraser boilers of similar type. The grate surface of each is about 30 square feet, and they evaporate 5,000lb. of water per hour. The feed-water is pumped through two feed-water heaters before reaching the boilers. The working pressure is 160lb., for which the boilers are designed.

The same arrangements of weighing coal (on weighbridge and balance) and of measuring feed-water by meter are here employed as at Eccleston-place, and the same kind of coal—best Welsh smokeless—is used. The piping also is similar, steel pipes with copper bends, 8in. diameter, all slung from

brackets above to allow of easy expansion. A complete double steam service to each engine is given.

The chimney shaft is 160ft. high, 11ft. square at base, and 8ft. square at the top.

ENGINES AND DYNAMOS.—Willans engines are installed throughout, compound and non-condensing.

Two 80-h.p. engines run the balancing machines.

Two 140-h.p. engines come next, for the first set of 225-volt dynamos. These engines were specially made for this station, and run at 170 revolutions with extra long stroke.

Next, there are six 200-h.p. engines driving Crompton and Elwell-Parker dynamos, and, lastly, one 350-h.p. Willans three-line compound, strengthened.

The dynamos comprise two Crompton two-pole dynamos of 45-kilowatt capacity—the balancing machines—giving 120 volts and 375 amperes. The next group are two Elwell-Parker (E.C.C.) four-pole machines, giving 65 kilowatts—220 volts and 300 amperes (working usually up to 350 amperes). Of the six sets of 200 h.p., two are Crompton four-pole machines, 112 kilowatts (225 V. and 500 A.), and four are E.C.C. two-pole dynamos of the same capacity—very good working machines—which in practice give without trouble almost any output that the engine can generate.

The 350-h.p. engine drives a Latimer Clark Muirhead dynamo of 225 kilowatts (1,000 amperes at 225 volts). This set has been tested at the makers' at full power, and gave 84 per cent. combined efficiency. This dynamo is remarkable as having the highest efficiency of any machine of similar large output by these makers: the shunt current is 9·5 amperes at a full output of 1,000 amperes.

Copper-gauze dynamo brushes are used throughout, and sight-feed lubricators are fitted to all bearings, the oil being used again and again after being filtered.

It will be seen that there is an excellent selection of subdivided units at this station—any power from 180 h.p. up to 2,000 h.p. can be run at almost full load. Very particular attention is paid to this point—the great aim of the engineer-in-charge is always to run the engines at full load as long a time as possible. Continued care in this direction often makes the difference between running the plant at 50 per cent. and at 65 to 70 per cent. efficiency—a difference that soon shows with an output of some thousands of amperes. An illustration will show how careful are the engineers at the station. At about 11 o'clock at night the load is generally 1,600 to 1,700 amperes, and at 11.30 it has dropped to 1,400 amperes; this latter load can just be taken by the two slow-speed engines, therefore the 200-h.p. engines are shut down directly the load falls to this point, and the two smaller engines take up the load and work for a certain time at full efficiency. The same consideration of high efficiency by running at full load governs all the combinations as far as it is possible to accomplish. It is not contemplated to use larger units than 350 h.p. on the Westminster system.

SWITCHBOARD.—There are seven feeders going from the switchboard to Oxford-street, Mount-street, Curzon-street, Arlington street, Grafton-street, Bond street, and Hanover-square. The switchboard is of the same type as those in use at the other stations. Automatic magnetic cut-outs are provided for every dynamo. The board is fitted with its full complement of voltmeters, but in practice the pressure is read on a pair of voltmeters placed on the gallery rails in front, carefully calibrated every week. The pressure at the feeding points is so regulated that consumers get 100 volts at their lamps.

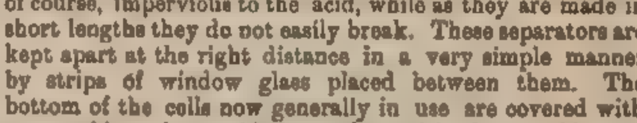
ACCUMULATORS.—The battery of accumulators is of the same kind as at the other Westminster stations—two sets of 56 Crompton-Howell 500 ampere-hour cells, of which 12 are regulating cells. There are also four "milking" cells to each set. The latter, it may be mentioned, are cells kept charged in constant readiness to be put on to any defective cell, and bring it rapidly up to full potential.

At Davies-street there have been certain improvements and perfected arrangements lately introduced by the resident engineer, Mr. Foster, to which some special attention may be directed. Users of accumulators generally, and station engineers where batteries are employed in particular, will be interested in these details of battery maintenance.

We may first, however, describe the manner in which the cells are washed out while in use. All secondary batteries have a certain tendency to short-circuit by the fall of dirt or sediment. The whole battery is regularly washed out three times a year, and this operation is so arranged that it can be done while the cells are in operation and with a minimum waste of acid. The apparatus consists of an acid-pump and two lead tanks. These tanks are placed so that one overflows into the other, the last, if necessary, into a lead sink leading to the drains. When the cells are to be washed, an extra supply of acid at the ordinary specific gravity is mixed in the lower tank. The cell to be cleaned is stirred up well and the muddy acid is siphoned off to the first tank, while more clear acid is pumped in from the second tank. The muddy acid siphoned off passes through two filters—one of copper gauze and the other of two thicknesses of the best flannel. The acid is already fairly clear in the first tank, where the rest of the dirt settles as the clear acid rises and overflows into the second tank; from here it goes once more to wash out and fill up a second accumulator cell, and so on for the whole battery. The cells can thus be washed out while in use; the acid is used again and again; the plates are but little exposed to the air, or washed by water only. The last two conditions are very necessary to keep the plates in really good condition; if exposed to the air the charged plates rapidly heat and disintegrate by occlusion of gas, and if washed by water alone the plates have a tendency to sulphate. Apart from this, the comparative ease and economy of washing show this to be the best method of cleaning the cells.

The improvement mentioned above relates to the separators of the accumulator plates. Battery plates require to be firmly kept apart at a constant distance by separators made of some substance not affected by the acid. Ebonite or xylonite are the materials usually supplied, but they are curiously uneven in the quality of resistance to the action of acid, and sometimes become gradually eaten away till they no longer can support the weight of the plates. Again, the mud which falls clogs in the interstices, and tends to short-circuit the cell, instead of tending to drop away from all possibility of contact. Moreover, negative and positive plates touch on the same separator in the old form, and the slightest coating of mud leads to some discharge, and eventually to a bad short-circuit.

The improved separator is made of glazed vitrified earthenware in short lengths, sufficient to hold four plates.



Improved Battery-plate Separator.

The sides are so fashioned as to throw off any coating of mud that may fall. These separators are placed on the bottom of the cell end to end. Two rows carry one kind of plate only—say, the negatives; another two rows carry the positives, and there is thus no possibility of connection between them. They are easy to fix, move, or clean, and are, of course, impervious to the acid, while as they are made in short lengths they do not easily break. These separators are kept apart at the right distance in a very simple manner by strips of window glass placed between them. The bottom of the cells now generally in use are covered with pure rubber sheet; this is costly, and is also troublesome to clean. The strips of window glass which take their place with the improved separator are cheap, and can easily be brushed or washed clean. The plates are kept apart from each other by three glass tubes. Altogether this arrangement seems a sensible and practical improvement, and we shall expect to see it widely adopted.

In the station every care has been taken for the comfort of the working staff. They have a mess-room, complete with bunkers and a kitchen range. Mr. Foster has also opened a reading-room and library, which the men use after working hours, and which contain the daily papers, technical papers, and technical books.

(To be continued.)

MOTOR GEARING FOR ELECTRIC TRAMCARS.

In discussing the question of motor gears for electric traction purposes, the term "gearing" is best taken in its widest possible sense as implying a mechanical connection between the motor spindle and car or truck axle. Perhaps, fortunately in this case, it is quite possible to do so by reason of the vague meanings usually attached to the word "gear," which is made to imply not only a system of mechanism to increase or decrease the speed of the second motion shaft as compared with that of the prime mover, but also the simple connections between driving and driven axles running at the same angular velocity. There are, that is, three possible methods of gearing—increasing, decreasing, or preserving the same speed; in engineering language—gearing up, down, or level.

When applied to street tramway traction by means of electric motors, the possibilities of gearing are seen to be limited at once, so far as this country is concerned, in the first place, by the restriction placed by the Board of Trade upon the velocity of street traffic—that is, upon the speed in revolutions per minute of the tramcar axle, from 60 to 120 revolutions being practically the limits within which it is permissible to work.

The average power which is required to keep a car in motion is not very great; at the outside, on bad roads with heavy grades and a full load of passengers, it should not exceed 12 h.p. to 20 h.p., whilst on ordinary lines it will not reach half this amount. Even with a 20-h.p. motor, however, the speed of motor axle usually employed is much in excess of that named as practically the highest limit of the car axle, and therefore the gearing or connection between the two axles has hitherto been designed, as a rule, for decrease of speed.

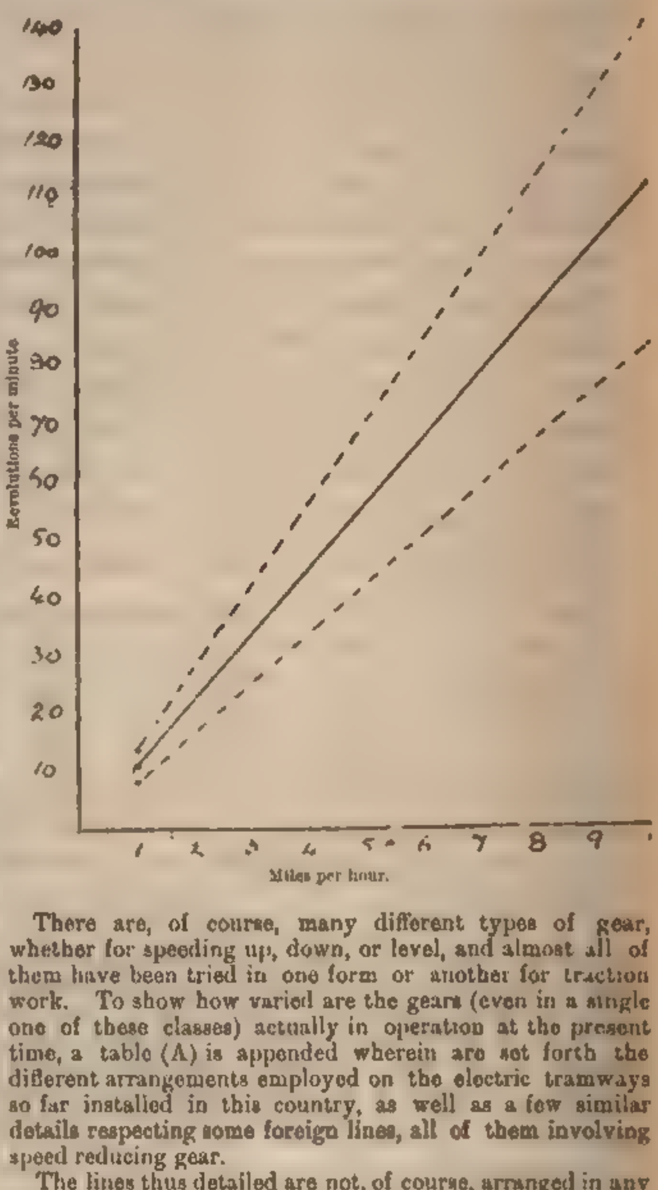
This may be largely due to the fact that electric motors were at first machines built with armatures designed to run at high speeds in a weak magnetic field, and although a brief examination into the development of electric tramway motors generally will be found to show continual progress towards a reduction in armature speed, combined with increased strength of magnetic field, for similar outputs, we are not yet sufficiently advanced (if, indeed, it should prove actually possible) to secure quite as great an electrical efficiency in these latter types as in the former ones. The total or commercial efficiency may not, however, differ very materially in the two cases, because the loss in motor efficiency is to a large extent made up by the gain secured when mechanical gearing between the motor and car axles can be avoided.

The limitations of speed attainable by the car axle are of course easily reckoned, but it may be useful to set them out in tabular form to serve as a reference, and thereby save trouble of calculation. The following table therefore shows the number of revolutions per minute of a given size of wheel at different horizontal velocities.

Revolutions per Minute.

Inches diam.	Miles per hour 1	2	3	4	5	6	7	8	9	10
24	14	28	42	56	70	84	98	112	126	140
26	13	26	39	52	65	78	91	104	117	130
28	12	24	36	48	60	72	84	96	108	120
30	11·2	22·4	33·6	44·8	56	67·2	78·4	89·6	100·8	112
32	10·5	21	31·5	42	52·5	63	73·5	84	94·5	105
34	9·8	19·7	29·6	39·5	49·4	59·2	69	79	88·9	98·8
36	9·3	18·6	28	37·3	46·7	56	65·3	74·7	84	93·4
38	8·8	17·6	26·5	35·3	44·2	53	61·8	70·7	79·5	88·4
40	8·4	16·8	25·2	33·6	42	50·4	58·8	67·2	75·6	84

The diagram shows these limits in a graphic form, the dotted lines representing the revolutions of a 24in. and 40in. wheel respectively, and the full line those of a 30in. wheel—the size usually employed in tramcar working. Even with the wheel of smallest size—24in.—which obviously is a minimum dimension for ordinary work, the greatest speed in revolutions does not exceed 140 per minute; whilst an inspection of any electric motor manufacturer's price-list will show not only that, roughly speaking, speed and output vary inversely with one another, but that the speeds of highly efficient motors, suitable for traction work, so far as the power required is concerned, are seven or eight times as much as that of the smallest wheel above mentioned. The necessity, therefore, of a speed-reducing gear is obvious, if we are to aim at high electrical efficiency; the only points for decision are those which involve the type of gear chosen, since it might be easy to lose in the latter all the advantage gained by the superior efficiency of the motor itself.



Miles per hour.

There are, of course, many different types of gear, whether for speeding up, down, or level, and almost all of them have been tried in one form or another for traction work. To show how varied are the gears (even in a single one of these classes) actually in operation at the present time, a table (A) is appended wherein are set forth the different arrangements employed on the electric tramways so far installed in this country, as well as a few similar details respecting some foreign lines, all of them involving speed reducing gear.

The lines thus detailed are not, of course, arranged in any strict chronological order, although as a matter of fact they fall into a kind of sequence simply by grouping together first those employing a double-reduction gear, and secondly, those which use a single reduction only. The former came first into use, owing largely to the reason already given—the high speed of motors—and it has only been during the past three or four years that the introduction of slower-speed motors made it easy to obtain an equal, if not greater, total efficiency by doing away with one set of gears, whilst still preserving a high electrical efficiency in the motor.

The average reduction with the double gear is nearly 9 to 1, the single reduction being, of course, about half this amount. Before discussing the various types of gear, there are one or two inferences—confessedly imperfect and incomplete however—which may be drawn from the figures in the table. Looking at the matter quite generally, it is evidently advisable to keep down both the speed and weight of motor and gear, whilst preserving, or even increasing the output in brake horse power. If, therefore, the speed and weight be multiplied together, and the product divided by the output, the resulting figure for each line may be looked upon to some extent as a figure of merit, obviously the smallest being the best. Approximately these figures are as follows.

TABLE A. GEARED MOTORS.

Line.	How reduced, and amount.	Type of gear.	Speed of motor (revs. per min.)	Weight of motor.	Weight of gear	B.H.P. of motor.
Bessbrook	double : 8·3 to 1	1. Straight spur. 2. Sprocket wheel and chain.	850	24cwt.	3cwt.	20

Southend	720	Guernsey . .	1,714
Birmingham ...	805	Blackpool	1,760

The position in such a "scale of merit" of the Guernsey equipment—the motors of which are probably working very much under their real power—shows, however, that many other points beside those named must be considered, not the least important being that of prime cost. High speed motors are, as a rule, not only more efficient in operation, *quâ se*, but decidedly cheaper to build than those designed for very low speeds: they should weigh less, and therefore involve less dead load and waste of propelling energy. The item of cost alone may vitiate the value of any such list as that just given. What may be aimed at—if it be possible for outsiders—is rather to arrange the systems according to the "revolution—hundredweight—sovereign" per horse power for a given electrical efficiency.

Then, again, the question of overload is highly important: by cutting down the weight here and there, a large saving may be made on the dead load; but when the inevitable strains come on—both in the armature and fields (and probably electric motors are nowhere else strained so much or undergo such changes of load as when employed for traction work) the result is that breakdowns become frequent, and the expense of maintenance therefore greater. It may be very wise policy to carry a little extra weight in the motor, if only to be prepared for maximum loads under bad conditions.

But however imperfect the above figures may be, they certainly serve to show considerable development in the more recent lines as compared with those first established, such as the Blackpool, Brighton, Bessbrook, and Portrush tramways. Taking, for instance, the extremes of the so called "scale," the Blackpool motors, with a speed of 800 revolutions, only give an output in horse-power of ·45 their weight in hundredweights. The South Staffordshire motors, on the other hand, have a speed half as great, whilst the ratio of output to weight is as much as ·92. The enormous advances made of late years in the design and construction of electric motors could not be more clearly illustrated than by such figures as these. Moreover, they serve to show the superiority of single-reduction gear as compared with that involving an intermediate shaft between the motor and car axles. The margin which is given by a design similar to that used on the South Staffordshire line is much in excess of any saving to be effected, either in the first cost of double reduction motors, or in their dead-weight and efficiency, with consequent economy of operation. Even taking the Birmingham line, which is the most modern of those employing double-reduction gear, the percentage of output to weight is less than with the South Staffordshire motors, being ·87, as compared with ·92, whilst the speed of the former is nearly twice as great. Dependent, of course, upon the extensive, and therefore cheap, manufacture of standard low-speed motors, together with economical production and transmission of electrical energy, there can be no doubt that a single-reduction type of gear is at present the most satisfactory for general use. The next step—viz., that of driving direct, and abolishing all intermediate connections by mounting the motor armature upon the car axle, or coupling them together with side rods—has been already taken with some degree of success, but it is questionable whether for the low speeds possible on tramways in this country the saving thus effected by doing away with mechanical losses would make up for the reduced electrical efficiency of the motor.

(To be continued.)

DESIGN OF ALTERNATING-CURRENT MOTORS.*

BY EMIL KOLBEN.

(Concluded from page 395.)

III. *Determination of the Magnetism Current and the Load Current.*—The well-known method of finding the idle current of a transformer applies equally well to motors also. If y, y_1, y_2, Fig. 8, are the mean lengths of the magnetic circuits and B, B_1, and B_2 the $\sqrt{\text{mean}^2}$ values of the induction densities in the field, the air-gap and the armature, H and H_2, the corresponding values of the magnetising forces, then the total number of ampere-turns required on the field of a motor of $2p$ poles at no load will be

$$i\,N = \frac{10}{4\pi}\,2p\,(2y_1 B_1 + H y + H_2 y_2);$$

hence the $\sqrt{\text{mean}^2}$ value of the magnetising current

$$i = \frac{1{\cdot}59\,p\,(2y_1 B_1 + H y + H_2 y_2)}{N} \quad . \quad . \quad (16)$$

* From the *Electrical World*, New York.

We see at once that i will reach a high value if high frequencies (such, for example, as used generally in American practice) are employed, for then the number of pairs of poles must at least have the value of $p = 5$, in order to come down to reasonable speeds. The chief factor, of course, is the air-gap reluctance, and as the gap is, from mechanical reasons, the same for a certain size of motor, whether it is run on high or low frequency circuits, the magnetising current will increase with the number of poles, and consequently with the frequency.

The idle current, or the current which the motor takes when it is running free, will be but little different from the magnetising current, as the actual work of w watts performed by the motor due to friction and copper losses in armature and field will be very small. If $i_1 = \frac{W}{E}$ is $\sqrt{\text{mean}^2}$ current due to this work, then $i_2 = \sqrt{i^2 + i_1^2}$ is very closely equal to i, as will be seen at a glance from Fig. 9. If the value of i_2 should differ considerably from the calculated magnetising current, then the design of the motor is faulty, for then there must be false currents induced in the armature conductors, which become a source of loss of energy, and by this the value of i_1 and with it that of i_2 will increase largely. This fact will be also at once evidenced by a considerable slip even at no load.* The full-load current, I, can now be found in the following manner. The magnetising current at full load, although somewhat smaller than at no load, on account of the reduced induction densities in the iron, may be taken equal to i without an appreciable error. The useful energy delivered by the motor is

FIG. 8.

FIG. 9.

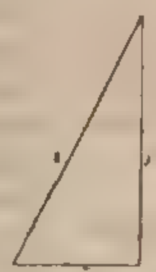

FIG. 10.

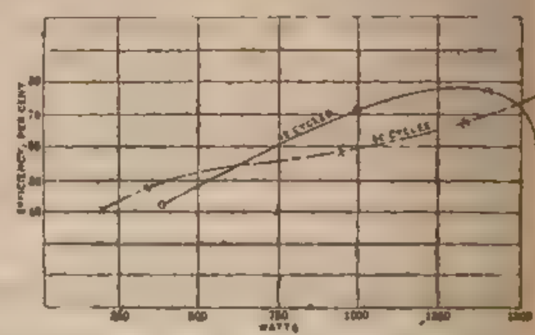

FIG. 11.

W watts and w_1 the energy due to copper and friction losses. From these we find the true working current at load :

$$I = \frac{W_1 + w_1}{E},$$

and the actual current will result from the combination of I and i according to diagram, Fig. 10, and its $\sqrt{\text{mean}^2}$ value will be :

$$I = \sqrt{I^2 + i^2} \quad . \quad . \quad . \quad . \quad . \quad (17)$$

With this value the section of the field wire and the copper losses in it should be accurately verified.

IV. *Motor Efficiency.*—The total efficiency may now be found exactly by calculating the following losses :

1. The hysteresis loss, w_h, and eddy-current loss, w_e, from the known maximum induction densities, B and B_2, from the cubical contents of the iron in the armature, c and c_2, cubic centimetres, and from the frequency, n, thus :

Hysteretic watt loss :

$$w_h = a\,n\,(c\,B^{1.6} + c_2\,B_2^{1.6})\,10^{-7}$$

where the Steinmetz hysteretic coefficient, a, has the value $a = 0.003$ for good sheet iron.

Eddy-current watt loss :

$$w_e = C\,n^2\,(c\,B^2 + c_2\,B_2^2)\,10^{-11}$$

where the eddy-current coefficient, C, has the value $C = 0.004$ for sheet iron of five millimetres thickness.

By careless design, a considerable loss may be caused through the leakage field producing strong eddy currents in the field conductors themselves and in the solid iron or metal frame holding the iron discs together.

2. The copper loss in the field from the full-load current, I (see equation 17), and the resistance of the field winding, R :

$$w = I^2 R.$$

3. The copper loss in the armature from equation (10) :

$$w_1 = u\,\frac{E_1^2}{R}.$$

4. Friction losses due to the bearings and the air resistance at full speed to be easily estimated or taken from tables of mechanical text-books.

Fig. 11 gives an idea of the variations of the total motor efficiency with the output. The two curves are plotted from results of test on an Oerlikon 2-h.p. single-phase motor designed to work on a circuit of 42 cycles.

* These false currents are inevitable with single-phase motors, as the field strength is fluctuating. With three-phase motors the *field is entirely homogeneous* and false currents are thus obviated.

ON THE ESTIMATION OF ELECTRICAL RESISTANCE BY MEANS OF ALTERNATING CURRENTS.

BY F. KOHLRAUSCH.

A paper on the above subject, of which an abstract is given in the *Foreign Abstracts* of the Institution of Civil Engineers, is published in the *Annalen der Physik und Chemie.* The following is the abstract :

The author has investigated the conditions and limits of accuracy in the measurement of resistances by his telephonic method. The apparatus is similar in principle to the metre-bridge, but the wire is three times the usual length, and has a resistance of 10 ohms. Two extra coils of 45 ohms can be inserted symmetrically, or both on one side of the bridge. The telephone is in connection with the two ends of the wire, and, in place of the usual battery, the secondary of an induction coil is in circuit with the rider and the middle terminal of the bridge. The coil generally used by the author has a solid iron core. The resistance of the primary is five ohms, and that of the secondary 30 ohms. It is driven by an accumulator, the interruptor being a platinum point dipping into mercury under distilled water, and making about 85 vibrations per minute. The platinum point is in connection with the negative pole. In measuring a resistance the rider is adjusted until the sound of the induction coil is no longer audible in the telephone.

The author arrives at the following conclusions. Under favourable circumstances the error by this method is less than one part in 10,000. If the position of minimum sound is indefinite by reason of polarisation, or of the self-induction or the capacity of the apparatus, then the middle point between two positions of equal intensity of sound gives the relation of the resistances with tolerable accuracy. The construction of the coils is a matter of some importance. Up to about 1,000 ohms, the ordinary bifilar winding gives good results, but at 4,000 ohms the error may be about ½ per cent., and the position of minimum sound is ill-defined. This error increases, according to Wien, with the square of the capacity and of the resistance. Coils made after the method of Chaperon, in which the successive layers are wound in opposite directions, are free from this defect, and may be used up to 30,000 ohms. It is better to use several small

coils instead of a single large one in making up a rheostat of high resistance, on account of the greater capacity of the apparatus in the latter case. Thus five coils of 1,000 ohms in series gave a well defined minimum, whereas with a single coil of 5,000 ohms the telephonic method was almost worthless. By the use of an adjustable condenser suitably arranged, the disturbing effect of the capacity of the coils may be in a great measure eliminated.

The error due to polarisation decreases as the resistance and the surface of the electrodes is increased. With polished electrodes, when the product of the area in square centimetres by the resistance in ohms amounts to 250 or more, the probable error from polarisation does not exceed 1 per cent. But the author recommends that polished electrodes should only be used for special purposes. They should be thickly platinised until a matt surface is obtained. Such electrodes, of from 10 to 35 square centimetres area, used with resistances of from 50 to 8 ohms, may be considered free from polarisation, the error being under 0·1 per cent. In dealing with very high resistances it is necessary to keep the induction coil at a distance from the measuring apparatus, and to place both telephone and bridge in such a direction with regard to the lines of force that their disturbing effect may not appear. In measuring the resistance of a fluid, the influence of the electrostatic capacity of the containing vessel may be felt, and the same effect may be observed when the resistance is immersed in a water-bath. In both cases the difficulty may be got over by the use of an adjustable condenser. A bath of petroleum was free from this objection. If the resistance to be measured is considerable—*e.g.*, 100,000 ohms—disturbing noises, due to static charges, are heard in the telephone. These may frequently be sufficiently reduced by connecting some point on the circuit with the earth. In such cases the telephone may show signs of being unsymmetrical—that is to say, on reversing its connection with the bridge, or changing the direction of the induced currents, the position of minimum sound may alter, even as much as 4 per cent. This error is to be eliminated by reversing the telephone, and taking the mean of the readings. It is probably due to static charges, and was most marked when using an induction coil with a core consisting of a bundle of wires.

OUR COALING STATIONS AND OUR TELEGRAPHS.

The following has been sent to the *Pall Mall Gazette*:

"Sir,—A dead set is at present being made against the Queensland Government for sanctioning a contract which throws the first section of the proposed Pacific cable into the hands of a French company, thus placing the line at the mercy of French operators in case of war.

"No one, however, seems to recollect the extent to which the Imperial telegraphic communications, especially those with our coaling stations, pass through the territory of foreign Powers, none of which has any particular reason to wish well to England.

"Thus, of the existing cables to Halifax, Nova Scotia, and Esquimalt, only one—namely, that from Heart's Content to Cape Ray—passes through Newfoundland at a sufficient distance inland to be guaranteed from the attacks of foreign filibusters. This line communicates by two cables with Aspey Harbour, Cape Breton.

"Of the other lines, four in number, laid from Placentia, Newfoundland, to Sydney Harbour, Cape Breton, two pass between the French islands of St. Pierre and Grand Miquelon, in very shallow water, and two actually land in St. Pierre, which also commands most of the existing lines to the United States. The land line between Halifax and Esquimault, west of Winnipeg, is for hundreds of miles within easy reach of the United States border, and quite unprotected against filibusters. From Halifax to Bermuda there is only one line.

"In the West Indies our coaling stations have not one single direct telegraphic communication through British territory. Kingston, Jamaica, communicates with the Admiralty by lines passing through Cuba (Spanish territory) and the United States. Its communications with the other West India islands pass through Puerto Rico (Spanish) and St. Thomas or Santa Cruz (Danish); a very roundabout line of communication with the Transatlantic cables existing in the line stretching from Kingston to Panama, and thence by a line stretching north along the Pacific coast through all the Central American republics, Mexico, and the States, and south through all the South American republics to Buenos Ayres, this, and the South American cable to Europe *viâ* Madeira (Portuguese), Lisbon (Portuguese), and Vigo (Spanish). Antigua is dependent on lines passing through the French island of Guadeloupe or the Danish islands of St. Thomas or Santa Cruz. Roseau (Dominica) is isolated between Guadeloupe and Martinique (French): all the Southern West Indies, including the Imperial coaling station at Castries Bay (Santa Lucia) and Trinidad, are dependent on (*a*) a line passing through Martinique and Guadeloupe (French); (*b*) on a second *viâ* Trinidad to the Danish islands of Santa Cruz and St. Thomas; (*c*) on a roundabout route over the Brazilian lines to Rio and Europe, touching French territory at Cayenne, and Dutch territory at Paramaribo.

"As regards South Africa, with its great coaling station of Simon's Bay, and West Africa, with its bay of Sierra Leone, close to that strategic point of Cape Verde, to which Admiral Aube's plan attaches such importance, our telegraphic communications are as follows: (*a*) By a line stretching through Lisbon, Madeira (Portuguese), St. Louis (French), Dakar (French), and the harbour whence they hope in future to control the great trade routes converging on Cape Verde, to Sierra Leone, thence by Grand Bassam (French), and Monrovia (Liberian) to the Gold Coast, and Lagos, touching French territory *en route* to Assinie (?), if not also at Kotouna and Porto Novo; (*b*) for South Africa the cable extends from Madeira through the Canary Islands (Spanish) to Cape Verde, San Thomé, Loanda, and Beryuella [? Benguella] (all Portuguese), and thence to Simon's Bay.

"The same is the case with the East Coast route to South Africa, as the cable from Aden, after leaving Zanzibar, touches Portuguese territory at Mozambique and Delagoa Bay, skirting the French Comoro Islands, before reaching Natal.

"As regards India and the further East, including Australia, we have only one fairly safe route in the cable stretching *viâ* Gibralta and Malta to Port Said, thence down the Red Sea to Aden, and thence to Kurrachee, landing, however, *en route* at the Kuria Muria Isles, which are not fortified, and are at the mercy of any hostile cruiser. This is the only route by which in time of war we could communicate with Bombay, Point de Galle, and Singapore, and the section between Malta and Port Said is one very liable to be interrupted by volcanic disturbances. All the other lines to the East pass either through Russian or Turkish territory, whilst every line in the Mediterranean save that between Gibraltar, Malta, and Port Said is thoroughly under foreign control. Between Singapore and Hong Kong the line touches the French settlement of Saigon.

"Our communications with Australia and New Zealand are entirely dependent on the line stretching from Singapore to Port Darwin, and passing through Dutch territory in the Java land lines, thus materially affecting our control over the coaling stations of Thursday Island and King George's Sound. Aden and Mauritius communicate by a line not yet completed, which was all but being carried through Madagascar, and the French port of Diego Suares.

"In short, every coaling station in our Empire may be said to be in communication with the Admiralty by lines which either pass through foreign territory or are at the absolute mercy of foreigners, for it is obvious that in case of war with France it would be impossible to repair even the section from England to Gibraltar, still less that from Gibraltar to Malta, without fighting a naval battle to protect the repairing ship, and that such an interruption could be readily effected cannot be for a moment doubted. Trusting that the attention which has been called to the state of our Imperial telegraphic communication by the action of the Queensland Government may result in a thorough enquiry into the whole of this important subject, I am, Sir, yours obediently, "H. Reade.

"24, Lower Sloane-street, S.W., Oct. 25."

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

140 SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE PACIFIC CABLE.

Twice within a measurable period we have discussed this question, both times calling attention to it before any cable was made for or laid in this direction. The position of affairs has now changed, and the various people concerned in the matter are realising the fact that unless action is at once taken, it will be too late to obviate a grave defect in our cable system. In future years England will curse the very name of the cable authorities who have led to the existing system. The history of cable-laying, whenever it may be written, will show that such curses have been amply deserved. Before briefly recording the facts let us at once say that, considered from merely a commercial point of view, and not from the national point of view, the conclusions about the best system of cables may not accord with those we venture to put forward. Our view has always been that calculations as to cost and maintenance might be made from the purely commercial side, but that the system, while providing for commercial wants, should also be laid with a view to Imperial wants, and the difference in cost and in maintenance, if greater in the latter case, should be borne by the Imperial and Colonial exchequers. That is our thesis, and if the system as at present to be found is not in accord with these views, the sole reason has been and is that such a system does not meet with the views of the heads of the cable companies in Old Broad-street. We have not a word to withdraw from our article of November 25 last year—but why go over old ground? What exactly is required? The following are our conclusions on the subject:

First.—The mother country should be able at all times and under all circumstances, whether at peace or war, to correspond with her colonies without the communications being open to the inspection of foreign countries.

That proposition seems to us to be somewhat axiomatic and undeniable, but the fact remains that it is totally impossible. The mother country cannot communicate, putting aside Canada, with any single Eastern or Western colony except by the courtesy of a foreign country. Quite recently the fraternisation of the French and Russian navies has led to forcible political articles on England's unpreparedness in case of a coalition war. Sleeping with a pipe in one's mouth over a powder magazine is, comparatively speaking, safety to the condition of England at the present moment. Without troubling about matters outside the pale of this paper, we may say that in the event of war the probability is that English-owned cables would be of greater value to our enemies than to us. Examine the maps and see; do not take our word. France, Spain, Portugal, Russia, Turkey, Egypt do not love us, and only tolerate us because the hand is still heavy and cannot easily be shaken off. All our connections with the East are by these countries. By the courtesy of these countries we can communicate direct, but not otherwise.

Second.—This proposition has already been stated to the effect that the difference in initial cost

and cost of maintenance of a system suited to Imperial needs over that suited solely to commercial needs should be borne by the Imperial and Colonial exchequers.

In the case of the proposed Pacific cable the commercial return would be less than if the system was in short lengths, calling at different ports; hence the necessity of subsidies. If we had a cable or cables direct to Canada, and from Vancouver to Australia, these, with the Canadian land lines, would enable us to communicate direct to Australia and to any other Eastern colony, because the Eastern Extension and the South African lines radiate from Australia westwards, so that from London we could get directly through to Canada, Australia, and India. Hitherto the stumbling-block has been the demand of the cable companies. Colony has been played off against colony. The Press, both Colonial and English, has undoubtedly been educated to support certain demands, and no one seems to have formulated the true position. Have we now done so? If our propositions are granted, an examination of the books of the cable companies would show that not only have the lines been extravagantly worked, but systematically so; that they really earn higher dividends than have been paid, and so existing tariffs and subsidies are not warranted by the true facts of the case. We trust, therefore, that those interested in England being able to communicate directly with her colonies will examine more closely into the matter, and urge public opinion to make itself felt in this direction.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LIFTING WATER BY ELECTRICITY.

SIR, — In reply to your correspondent "J. G.", in this week's issue of the *Electrical Engineer*, there would be no difficulty in pumping the water from the well to the cistern by means of an electric pump, consisting of an electromotor and a three-throw ram pump, which could be coupled direct by spur gearing, or the pump could be belt-driven from the pulley of the motor. The power required at the motor would be about 2½ h.p. The power would be obtained from a dynamo driven either by the engine or waterwheel, and transmitted to the motor by cable. The power required at the dynamo would depend upon the size of the cable used, with due regard to economy in cable. The power required at the engine would be about 4 h.p., or at the waterwheel about 5 h.p. to 6 h.p. These figures are based upon the assumption that the pump is worked 24 hours per day. If it were only worked for 12 hours per day it would require double the power mentioned above.

We will be glad to give your correspondent any further information he may require if he will write to us direct.—Yours, etc., WYNNE AND BARNARD.

Newcastle-on-Tyne, October 28, 1893.

REVIEWS.

Continuous-Current Dynamos and Motors. By FRANK P. COX, B.S. The W. J. Johnston Company, New York.

We have often to eulogise American technical publications, because the authors have a directness which most English authors lack. They understand that a vast mass of detail matter about minutiæ is in elementary books out of place, while the English author must try to say a word about everything he knows to show he knows it. This book, however, while very good, hardly comes up to our standard of what an American book should be, perhaps because it includes too much. The chapters devoted to indicator diagrams and steam-engine calculations might with advantage be left out. They assume the student to have a knowledge which, this being an elementary book, he has probably yet to acquire. Taking the contents of the book as given, the matter is very fairly and sensibly given. Young students not yet familiarised with abstract formulæ, are assisted by the translation of formulæ into numerical examples. We are not quite sure that we agree with Mr. Cox in some of his deductions, but then, with all due respect, it is just as well to find opinions differing, otherwise books would become stereotyped and progress abolished. With certain minor exceptions, then, we should say that Mr. Cox has produced an elementary work of a valuable character, containing much valuable information given in an able manner. Especially useful will be the chapters in which he analytically and numerically considers the design of armatures and field magnets. It is just such numerical examples that show the young reader how to use the varied formulæ he meets with in his reading.

Town Councillors' Handbook to Electric Lighting. By N. SCOTT RUSSELL, M.Inst.C.E. Biggs and Co.

One of the chief difficulties in the progress of electric lighting is in the lack of elementary knowledge of would-be users. Town councillors hear of the electric light and see it on every hand, but the exact procedure to obtain it for their constituents, its properties, its probable cost, and its strong and weak points are unknown. It is for the purpose of supplying elementary information in these directions that Mr. Scott Russell has prepared this little handbook. In it he tells the reader of the law in its relation to electric lighting—how to and when to apply for a provisional order or a license. But far beyond this, he gives in simple language a slight insight into applied electrical matters; and, still more important to the councillor, discusses the question of rival illuminants. No matter how unfair it is to compare directly the cost of one illuminant with the other when indirect losses occurring with the one and not with the other are never considered, this comparison will be made. Happy for electrical work that the comparison will not swamp it, as lighting by electricity when general can be made to come as economically to the householders as can gas. Mr. Scott Russell has done yeoman service in preparing this little book, which will undoubtedly be of great service to all those connected with local administration.

SOME INTERESTING PECULIARITIES OF THE ALTERNATING ARC LAMP.*

BY THOMAS SPENCER.

Although arc lighting by means of direct currents has been practised in this country for nearly 15 years, it is only quite recently that an attempt has been made here to utilise the alternating current for that purpose, although it is a historical fact that the very first attempts made to introduce arc lighting for street illumination was by means of such a current. I refer to the Jablochkoff candle. Jablochkoff found that he had to use an alternating current to make his two carbon pencils, which composed his candle, burn away equally. Since Jablochkoff's time there has been a great deal of work done in Europe, and especially in Germany, where greater progress has been made in the electrical sciences than any other part of the eastern continent, towards utilising the alternating current for arc lighting, and I have the pleasure of showing you one of the latest productions of that country (both as to lamp and carbon to be used with it) this evening. The lamp itself, though, being an American production, it being manufactured by the Helios Electrical Company, of Philadelphia,

* Paper read at the meeting of the Electrical Section of the Franklyn Institute.

under patents of the German company of the same name. This lamp I will speak of later.

As I said before, it is only quite recently that alternating currents have been utilised for arc lighting. The first systematical attempt of the sort was, no doubt, that of the pioneers of alternating currents in this country, the Westinghouse Electrical Company, of Pittsburgh, Pa., when they put upon the market their well-known alternating series system. This was, no doubt, brought about by a circumstance, and that circumstance was the invention by Mr. William Stanley, who was then consulting electrician for that company, of a wonderful constant-current alternating-current dynamo. This machine I look upon as one of the most beautiful in its performance of anything in the whole range of electro-dynamic machinery. It was my pleasure to be so situated as to have the handling of two of the first machines of this kind sent out by the company—the performance of these machines were simply wonderful. I have time and time again switched one of these machines from full load—that is, 60 arc lamps, each taking 45 volts—to a dead short-circuit, with only a variation of a half ampere in the current, and this without any mechanical regulation. I would say, in passing, that with this machine the only thing to be feared was an open circuit, and that the safe way to run the machine was dead short-circuited.

The principle on which this machine worked was very vaguely understood for some time, the inventor himself having a very complicated explanation, based on armature reaction, but no doubt the correct explanation is this: The machine has an armature of the tooth form, on which there is wound quite a large amount of wire, and as a result the E.M.F. generated by the machine is quite large, but on account of the way the armature is constructed there is a large self-induction. These two factors being so great the actual resistance in the current becomes insensible in comparison with them, so the current is practically independent of the resistance in circuit; or, in other words, [illegible]

This can more clearly be seen from the following equation, where

c is the current;
E the E.M.F.;
R the total resistance in the circuit, including the resistance of the arcs of the arc lamps;
L the coefficient of self-induction;
$p = 2 \pi n$ where n is the frequency.

$$c = \frac{E}{\sqrt{R^2 + L^2 p^2}}.$$

Now, if E and L are very large in comparison to L R, we have

$$c = \frac{E}{Lp};$$

or the current is constant, no matter what the external resistance may be, providing it is not too large.

With such a machine the Westinghouse Company thought they had solved the problem of arc lighting by means of alternating currents, but in this they were mistaken; in fact, this was really the easiest end of the problem, and although this machine has now been known for over three years, this system has made little progress, due to the fact that these lamps did not come up to the standard set by the direct system in common use.

The fact is, that here in this country an alternating-current arc lamp has been studied entirely in those lines on which a direct-current lamp was found to give the best results, while European practice shows plainly that a treatment entirely different should be followed.

Let us study the arcs formed by the two kinds of currents; first, as regards the distribution of their illuminating power.

Let Fig. 1 represent the two carbon pencils in a direct arc lamp, where the upper pencil is supposed to be positive. Suppose we take a, the arc, as a centre of a circle, and suppose we plot off on each radii the candle-power in the direction represented by it. Now, if we trace a curve through all the points thus found, we have a curve, as shown in Fig. 1, from which we see that nearly all the light is thrown down in the direction a b. This is due to the fact that nearly all the light from an arc lamp comes from the crater on the positive carbon.

Fig. 2 shows the curve for an alternating arc, which you see is altogether different from the first curve, there being four wings instead of two, as in the first curve, and these wings are shorter.

This distribution of light, of the alternating arc, has always been looked upon as a failing, for the light represented by the two upper wings is usually thrown up and wasted, especially if the lamp is out of doors. This defect has been in a great measure remedied in the lamp before

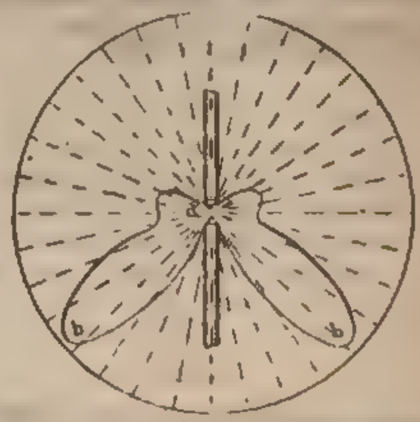

Fig. 1.

you, by making the lamp focussing—that is, making the arc remain always in the same place, and using a white reflecting plate close above the arc. This plate will reflect something like 80 per cent. of the light incidenced upon it. There is another point in which there is a great difference in the two currents; it is this: One of the first things noticed about the alternating current was that there was very little arcing at switches where currents of large amperage were broken. This peculiarity was looked upon as a particularly valuable feature, for in the construction of switches the arcing was the principal thing to be guarded against, especially where high voltages were to be broken. I think, with the general introduction of alternating-current plants, this property is not appreciated. One has only to stand and watch the arc that follows a plug

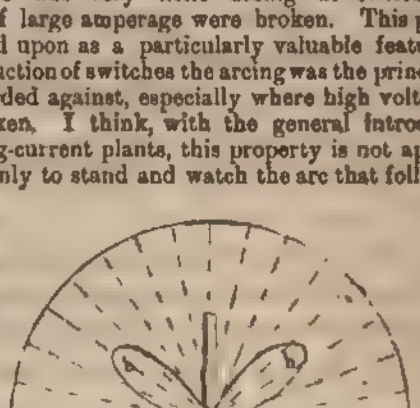

Fig. 2.

switch in a direct arc switchboard, where the voltage is not over 2,500 volts and 10 amperes, and to imagine what the result would be if the alternating current should suddenly acquire the same property, on some of the beautiful switchboards for incandescent lighting of about the same voltage and much larger amperage, when the switches began to be thrown. There has been a great many theories about this property of the alternating current, but it is about settled that it is due to the fact that at a certain instant there is no current flowing to keep up the temperature of the vapour through which the current is flowing sufficient to maintain a strong, hardy arc, and as a result it is easily broken. Now this property, although it is just the thing we want, as far as switches are concerned, is far from desirable when we

come to use the alternating current for arc lighting. It is evident from what has been said that an alternating arc is much less hardy than that of a direct current of the same current density. We see, therefore, that it is a mistake to follow the lines of the direct system in devising an alternating system. What is desired is to get as much heat generated as possible in the flame, so as to keep up the temperature of the vapour through the time when the generation of heat practically stops for the instant. This is best illustrated by Fig. 3, where *a a a* is the current curve and *f f f* the temperature curve of the flame for the same instants, and *c c c* the minimum temperatures, which the flame reaches. Now, *c c c* will be larger the larger the current, and the arc will be more hardy.

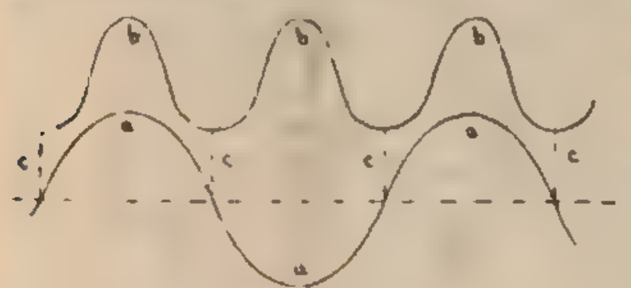

Fig. 3.

So it would seem that the only way to produce a good alternating arc lamp is to use a large current, but a large current means a large candle-power, unless we lower what is called the counter E.M.F. of the arc, or the drop in E.M.F. which occurs at the crater itself. If we refer to Fig. 4, where A and B are the carbon points, the distance between them being exaggerated for convenience, and suppose the drop in potential plotted from one point to the other, assuming A the positive carbon, we find for the direct system, at the point *a*—that is, at the crater—that there is a sudden drop of the potential to a point marked *b*. This drop is what is known as the counter E.M.F. of the arc. For the remaining part of the distance the drop is more gradual, and varies as the current. This is the part due to the drop in the flame itself. So it is apparent that if we could reduce the counter E.M.F., leaving as large a loss of energy in the flame as possible, we would get an arc which would be much less affected than with a smaller current, at the same time without any larger output in watts for the lamp. This has been done in the lamp before you by the use of a special low-voltage carbon, which allows this lamp to give an illuminating effect with 28 volts and 10 amperes, equal to about that given by a 45-volt seven-ampere direct-current lamp. Referring again to the counter E.M.F., I would say that there has been a great deal of controversy over

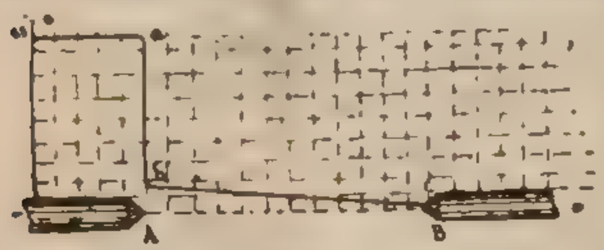

Fig. 4.

whether such a thing really existed. I myself am one of the party who believe in its existence. In fact, there is a strong current setting in the direction of that belief. I myself have been convinced that there was a real E.M.F. in the arc by studying the alternating arc itself; in fact, there are reactions in the arc which could only be explained by the existence of a counter E.M.F. A gentleman in England, whose name I have forgotten, has recently tried an experiment of heating a carbon juncture in a hydroxygen flame, and was able by this carbon thermopile to get quite a difference of potential between the two carbons. He claims that his results were such as to account for the counter E.M.F. of the carbons had been raised to the temperature of the arc. Also quite recently Silvanus Thompson has tried quite a number of experiments bearing on this subject, and has come to the conclusion that the E.M.F. is the result of the energy which disappears as latent heat in the volatilisation of the carbon in the crater.

There is another peculiarity of the alternating arc which is the most serious objection to it, from a commercial standpoint, and that is the noise made by the arc. Even this has been attacked and so overcome that it is no longer the objection it was in the early forms of lamps using alternating currents. The cause of this noise is due to the constant variation of temperature of the flame, as I have described already, which produces an expansion and contraction in the surrounding air. The result is a musical note depending on the frequency of the current. That there is a real rise and fall, even in the light given out by

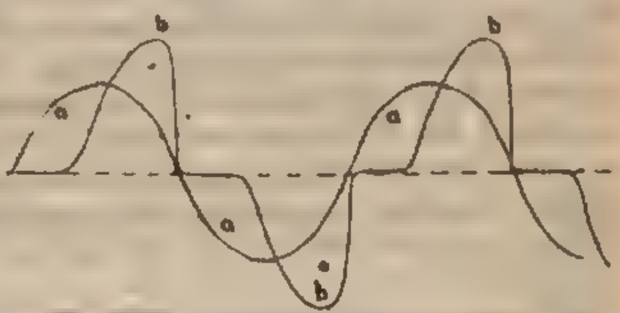

Fig. 5.

the arc, can be shown by moving a white stick, or, better, a short piece of white wire moved back and forth rapidly near the lamp, when the white band, caused by the preciseness of impression in the eye, will be observed to be broken up into bands, showing that the light is varying with the alternations.

The noise is, I find, a function of the form of the current curve. This came under my notice in trying to substitute a choking coil in place of a resistance to absorb the excess E.M.F. above what was wanted at the arc. I noticed that the noise was considerably increased by the coil over the resistance. You can see that this is the case by the experiment I have arranged before you, which is so wired that either the resistance or coil can be used. You will observe that when the lamp is burning on the coil, there is considerable more noise than when the resistance is in circuit. The reason why this is the case will be explained by referring to Fig. 5, where let *a a a* be a simple curve of sines, which is very near the case, with a well-designed alternating dynamo. Let this curve be deformed by the current represented by it, passing through a choking coil with iron. The deformed curve will be something like the curve, *b b b*, due to the lack of constancy of the permeability, and to hysteresis in the iron. If we look at this

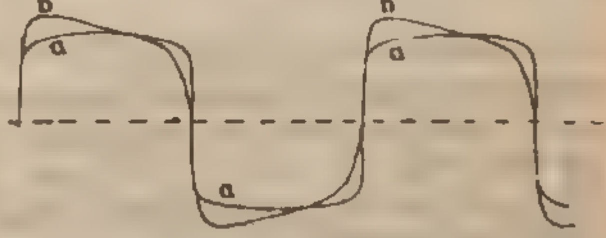

Fig. 6.

curve we will notice an abrupt rise in it, which means a sudden rise of temperature in the flame; or, in other words, we would have a sort of explosion, and as a result this form of current curve would be more noisy. There is no doubt but the form of the current curve, which would be the best as far as sound is concerned, is that of the simple sine curve, for in this curve the current rises gradually, and sinks away gradually.

One thing which puzzled me for some time was that I found that a choking coil, which contained no iron, even made more noise than when a resistance was used. As there was no changing permeability or hysteresis in the arc, the cause for this increased noise was not quite so apparent. The explanation, no doubt, lies in the fact that no machine gives a true sine curve, but in most cases the curve is symmetrical as regards the rise and fall, as will be

seen by the curve *a a a*, Fig. 6, which is supposed to be the form of curve given by the dynamo. Now, a choking coil without iron would deform this curve to the form shown in the curve *f f f*, on account of the change of phases which it would bring about in the different harmonics which make up the compound wave coming from the dynamo.

It is found that when the frequency is reduced the noise is greatly decreased: for instance, lamps burned by means of the current supplied by some dynamos recently turned out by the Westinghouse Electric Company, which have a frequency of 7,200, practically made no noise. On the other hand, Mr. Tesla, by going the other way—that is, by raising the frequency above the audible point—made a perfectly quiet arc, but as high frequency introduced so many other objectionable features, I hardly expect to see this method very extensively introduced.

There is what you might call, still, a mechanical way by means of which the noise can, in a measure, be reduced, and that is by running with a short arc. The reason for this is self-evident, for by so doing you keep the flame well inside the hot walls of the carbon, which do not fluctuate as much in temperature as does the flame; as a consequence the surrounding air is not so much affected, and the result less noise.

I will say, in closing, that an alternating arc lamp is something very much to be desired, as it forms one of the links in a chain towards which all electrical engineering is now drifting. I refer to the designing of a central station so that all kinds of electrical work can be done by one kind of current, which can be supplied by one kind of machinery at the central station. Not as now by several different kinds, as I saw to-day, a station using at least five different kinds of dynamos. That the alternating current is to be the current settled upon no one will deny, on account of its great flexibility. Therefore, the alternating arc lamp has a great future before it, even greater than the series arc has had in the past. It therefore gives me pleasure to exhibit to you to-night a lamp which, I believe, embodies in its construction the most advanced idea in alternating arc light engineering.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE III.

(Concluded from page 401.)

A company was formed in 1864 to carry out the works. A weir was constructed during favourable seasons of low water, in 1864-5 and 1865-6, across the river, which is about 500ft. wide. The fall immediately at the weir is not great, but there are rapids below it, and by placing the turbine house above the weir and constructing a subaqueous tailrace 620ft. long, a fall was made available, varying from 15·6ft. in low conditions of the river to 13·7 in high conditions. The turbine house contains three turbines of 200 h.p., 200 h.p., and 300 h.p. The turbines are axial flow pressure turbines with vertical shafts, driving a common horizontal shaft by bevel wheels.

Two hundred horse-power is taken directly from one of the turbines and transmitted to a factory on the hill above the turbine house by a steel shaft 550ft. long. From the same shaft also about 22 h.p. is taken off by a subsidiary wire rope transmission, which passes down the right bank and then across the river to a pulp factory. There remain about 530 h.p. to be dealt with by the main wire rope transmission, which passes directly across the river to the left bank, and then along the river bank up the stream on the left shore.

As to the turbines, there is nothing of special interest, except that they are constructed with a partition dividing them into two rings of buckets. During low conditions of the river, when there is a good fall, the outer rings of buckets only is used. When the fall is smaller, both rings are used. This compensates a little for the variation of normal or most economical speed of periphery, with variation of fall. The turbines make 34·28 revolutions per minute. The turbine regulating sluices are under the control of a relay governor. An auxiliary 6 h.p. turbine works the main sluices of the inlet chamber. There is a friction brake on the main shaft of the turbines which is thrown into action by the governor if the speed exceeds a certain limit. Then, if a rope breaks, the friction brake comes into action and stops the turbines. Connected with the brake is an apparatus for determining the power transmitted by the ropes. But the author has not been able to learn whether this is satisfactorily used.

We have now to deal with the principal wire-rope transmission across the river. It has been seen that the turbines drive by bevel wheels a horizontal shaft, each turbine being capable of being disconnected by putting its bevel pinion out of gear. The horizontal shaft makes 80 revolutions per minute, and carries at its driving end two principal rope pulleys of 14·75ft. in diameter. From these pulleys two cables cross the river in a single span of 385ft. to a pulley station in the river at the left bank, where the direction of the transmission is changed by bevel gearing, and thence the transmission passes up the left bank of the river.

The two principal rope driving pulleys are not keyed on the horizontal driving shaft, but run loose on it. Between them is a strong cross head keyed on the shaft, carrying bevel wheels on studs, which gear into bevel wheels fixed to the driving pulleys. If the tension in the two driving cables are the same the bevel gearing would have no action. But if there is any difference of tension, the bevel wheels permit one driving pulley to rotate faster than the other, so that equality of tension in the ropes is re-established. This differential gear has not, so far as the author is aware, been elsewhere adopted. Provision is made for keying either driving pulley on the shaft, in the event of one rope breaking and the power having to be transmitted through the other rope. The differential gear is then out of action.

The gross power in the horizontal driving shaft in the turbine-house is about 530 h.p., or, allowing for friction, say 500 effective horse-power to be transmitted to the factories, or 250 h.p. for each rope. Either rope is capable of transmitting at any rate a large fraction of the whole power temporarily if the other rope is broken.

This power is delivered by the ropes at the change station on the left bank. At that station about 22 h.p. are taken off by prolonging the second shaft of the bevel gearing and a subsidiary rope transmission. The remaining 478 h.p. is transmitted along the left bank to the first intermediate pulley station, at a distance of 370ft., by a pair of cables. Thence to the second intermediate station, distant 345ft., by another pair of cables. At 455ft. further is another or second change station, at which the direction is again changed by gearing. Thence the ropes pass to two further intermediate stations.

From the second intermediate station an underground shaft carries about 27 h.p. to 10 small workshops, and from the second change station, and the third and fourth intermediate stations, cables are carried back across the river to factories on the right bank. From the first shaft at the second change station, about 110 h.p. are distributed partly by a special rope gear, partly by vertical and underground shafting, to four factories, one of which is the large Mosersche Gebaude; and, from the second shaft of this station, a steel shaft transmits 200 h.p. to Scholler's wool factory. Between the turbine house and the second change station the cables consist of 80 wires 0·042in. diameter, in eight strands of 10 wires each, with a hemp core; diameter of rope 1·06in.; speed of rope, 62ft. per second. Smaller ropes are used in other parts of the transmission. The distribution has been described rather fully, because it is essential to learn how far wire rope transmission can be adapted to complex conditions, where many consumers require power.

It would appear that the rather complex arrangement of differential gear and double cables were intended originally to meet the case of having to drive by a single cable while the other cable was broken or under repair. It appears that under present conditions one cable would not be strong enough to transmit the whole power which is utilised; on the other hand, experience has shown that there is no necessity to duplicate the cable to avoid accidental stoppages. The total length of principal transmission is about 2,000ft.

The Schaffhausen installation has been an entirely successful undertaking, and has very greatly benefited the industries of the town. Some particulars of the extent to which the power has been utilised may be interesting.

Year.	Number of renters of power.	Average total h.p. supplied.	Rent from power. £
1867	13	121	345
1868	13	150	585
1869	14	180	730

The charge for power in 1887 varied from £4 16s. to £6 per horse-power per annum.

The total cost of the works appears to have been reckoned at

* Howard Lectures delivered before the Society of Arts.

£29,360 originally, and this, by writing off, stood at £24,664 in 1887.

As to the working of the system it appears that experience has proved that there is a greater loss of power in transmission in wet and frosty weather than was originally expected. When the maximum power is being used, there are oscillations of the ropes which drive the machines at irregular speed. The spinning factory suffered most from this and ceased to take power. This has led to the construction of a new power station and the adoption in the new works of electrical instead of wire rope transmission.

In some excellent lectures which were delivered before this society in 1891 by Mr. Gisbert Kapp, the method of transmission by wire rope is compared with the method of transmission electrically very much to the disadvantage of the former. "Till recently," said Mr. Kapp, "rope transmission held the field absolutely, not because it was perfect, but because there was nothing better. Now, however, we have something better in electrical distribution, and the flying ropes are being steadily replaced by the electric conductors." The use of the word "replaced" conveys a wrong impression. The wire ropes have not been replaced at Schaffhausen by electric cables, but an additional power station has been erected, and an electric transmission has been placed beside the rope transmission. It happened accidentally that at a visit of the author to Schaffhausen, about a year and a half since, the rope transmission was working while the electric transmission was stopped, having been temporarily disabled by a lightning accident. It seemed desirable to ascertain from Messrs. Rieter what view they took of the prospects of wire rope transmission, looking to the fact that they had the opportunity of knowing the results of the working of rope and electric transmission side by side. They were good enough to send answers to some enquiries. They say that at Schaffhausen the rope plant is expected to do more work than was originally provided for or intended; also, it was the first large installation of the kind and had some defects, which experience has shown can be remedied. Electric transmission, they say, has also been found to have some inconveniences. They, however, do not think that electric transmission will compete seriously with rope transmission for short distances, such as that at Schaffhausen, as I understand them; on the other hand, for long distances, they admit that electric transmission has the advantage.

Transmission at Tortona in Italy.—As early as 1876, and apparently independently of Hirn, an Italian engineer* erected a small cable transmission, worked from a waterwheel, at Tortona. There is a single span of 400ft. The waterwheel drives the first rope pulley by gearing, with a ratio of 19 to 1. The rope speed is 50ft. per second. The most interesting points about the transmission are (1) that, in spite of the disadvantages of gearing, and the smallness of the power transmitted (7 h.p. or 8 h.p.), the loss in normal conditions of working appeared to be only 6 per cent., and (2) that the substitution of water power and rope transmission for steam effected an economy of 60 per cent.

The Installation at Fribourg, Switzerland.—A company was formed in 1870, partly to acquire and work the forests owned by the town of Fribourg, partly to utilise and sell water power, and partly to carry out a scheme of water supply. This was to some extent a scheme in advance of any previous one, because the company acquired land which they proposed to lease to industrial undertakings, including in the lease a right to a supply of power from the plant of the company.

A dam, 40ft. high, was built across the River Sarine, near the town, in a ravine where it was not possible to construct factories. The company, therefore, acquired some level land about 300ft. above the river, adjoining a railway and otherwise well adapted for factories. The factories were to be worked by power transmitted by wire ropes from the power station at the river.

With the minimum flow of the Sarine and an effective fall of 35ft., 1,700 h.p. could be obtained. Provision was made for two turbine houses containing eight turbines of 300 h.p. each. Only two turbines have actually been constructed—one driving pumping machinery for water supply, the other driving a rope transmission. The turbines are Girard turbines, running at 74½ revolutions per minute. The turbine for transmission drives a horizontal shaft at 81 revolutions per minute by bevel wheels. This carries a 15ft. pulley with single groove driving the cable, by which power is transmitted to the plain of Perolles. The principal rope transmission consists of five equal spans of 500ft. each. The total distance to the sawmill, at which power is first taken, is 2,500ft., and the difference of elevation is 268ft. The rope pulleys are all 15ft. in diameter, and the rope is 1·08in. in diameter. The rope consists of 90 wires, ·072in. in diameter, in 10 strands of nine wires with hemp cores. The speed of the rope is 62ft. per second. At the sawmill a subsidiary transmission works a railway for carrying timber and using 50 h.p. This has a rope ⅞in. in diameter. From the shafting of the sawmill another subsidiary rope transmission takes 120 h.p. to railway carriage works, at a distance of 930ft. From the carriage works there is a further transmission of 60 h.p. by a ⅞in. rope a distance of 1,600ft., and thence by ropes ⅞in. in diameter to a foundry and chemical factory. The power is sold at the rate of 200f., or £8 per horse-power per annum.

It was at Fribourg that Messrs. Rieter introduced the plan of employing ropes, previously stretched, so than they should not require to be shortened after being some time in use. The ropes are stretched 0·71 to 2·6 per cent. of their length by a machine which compresses them radially, while a longitudinal tension is also applied.

The Installation at Bellegarde.—In 1872 a company was formed to utilise the water power of the Rhone, at Bellegarde, not very far from Genova. The total power of the river which is available is estimated at 12,000 h.p., but the original project, which was on a very large scale, has been only partially carried out, and the works have not been financially successful.

The water is led from a point above the Perte du Rhone, through a tunnel 1,800ft. in length, to the Valserine, near its junction with the Rhone. A turbine house has been erected, with five Jonval turbines, on a fall of 36ft., developing 630 h.p. each. The power is sold at 200f. to 300f., or at £8 to £12 per horse-power per annum. Quarries of deposits of phosphate of lime, a wood pulp factory and paper mill, a copper refinery, and other works, are driven by the turbines.

The turbines are in a gorge. The wire ropes are led from pulleys on the turbine shafts to a pulley station, distant 120ft. vertically above the turbines, and 200ft. horizontally. The total distance to the phosphate factory is 3,000ft.

The horizontal shafts driven by the turbines carry each two pulleys, 18ft. diameter, with ropes 1·28in. in diameter, consisting of 72 wires, ·081in. in diameter, with a hemp core. The rope speed is 66ft. per second. The greatest span at Bellegarde is 630ft.

The Installation at Gokak, in India. The most recent and one of the largest telodynamic transmissions has been erected at Gokak, in the southern Mahratta country, in India. This installation has been carried out by Messrs. Escher Wyss, of Zurich.*

The river falling over a high cliff has motive power enough for many industries. At present three turbines of 250 h.p. each (750 h.p. altogether) have been erected to drive a cotton mill of 20,000 spindles. The water taken at 2,300ft. above the fall is led by a channel to the edge of the cliff, and thence in a 32in. wrought-iron pipe. The pipe descends about 110ft. vertically on the face of the cliff, and then is inclined at about 30deg. to the horizontal. In the turbine house the three turbines are supplied by three 24in. branch pipes. The total fall acting at the turbines is 180½ft. The turbine wheels are 67in. in diameter, and they turn at 155 revolutions per minute.

The turbines are action or impulse turbines with partial admission; and they have horizontal axes, each turbine axis carrying a wire-rope driving pulley. There is a sluice valve, worked by hand, and a throttle or disc valve, controlled by a governor, to each turbine. The governor is a relay governor, in which a belt on speed cones drives differential gearing connected with the throttle-valve. If the governor moves the belt to either side of its central position the differential gear comes into operation, and opens or closes the throttle valve.

The shafts of the turbines carry wire rope pulleys 11½ft. in diameter. The rope speed is 93ft. per second; the ropes are 1in. diameter. At the top of the cliff is a rope station, with carrier pulleys 198ft. and 220ft. above the turbine shafts. The pulley for the tight side of belt is 11½ft. in diameter, that for the slack side is 8ft. in diameter. The distance from this station to the mill is 432ft., and there is an intermediate carrier station for the slack side of the belt, which would otherwise foul the ground. There are, of course, three ropes, one to each turbine. The installation was set to work in October, 1887.

Advantages and Disadvantages of the Telodynamic System.—The telodynamic system is adapted for transmitting and distributing power to distances of a mile or more, which are large compared with the distances to which power is ordinarily transmitted by shafting and similar means. On the other hand, it cannot seriously compete with electrical transmission in cases where the distance to be covered is reckoned by many miles. With this limitation it may be noted that—

1. It has the peculiar advantage that it transmits the mechanical energy developed by the prime mover directly without any intermediate transformation. In electrical distribution, a double transformation is necessary—a transformation into electrical energy by a dynamo, and retransformation back into mechanical energy by an electric motor. This double transformation involves waste of power and increase of capital expended.

2. The efficiency of transmission to such distances as those at Schaffhausen is undoubtedly very great; it is uncertain whether a similar amount of power could be distributed to an equal number of consumers electrically with as little waste of energy in the process.

3. The telodynamic transmissions which have been at work, some of them since 1864, have actually worked continuously, without serious stoppage, and have only failed to return an adequate profit where they were undertaken on a scale too large for the amount of industry requiring to be supplied with power in the locality.

4. Where, as at Bellegarde and Fribourg, the power station is 150ft. or more below the factories driven, the telodynamic system has an advantage over some systems, such as the hydraulic system, that there is no loss of efficiency due to difference of level.

On the other hand, it may be admitted that telodynamic transmissions, simple as they are mechanically, involve considerable cost. The pulley piers require to be lofty and strongly built. The maximum length of span hitherto accomplished is 630ft. at Bellegarde. Experience has also shown that the cost of maintenance is considerable. The cables must be replaced annually, and experienced workmen are necessary to make the long splices in the ropes.

One distinct disadvantage of the telodynamic system is that no means has been found of directly measuring, by numerous or continuous observations, the amount of power delivered to each consumer. So long as the power is distributed to very few consumers, it is possible to assess, with practical fairness, the charge to each, without such measurements of the power. But, in pro-

* N. Ruggeri, *Proc.* Inst. Civil Engineers, vol. l., p. 192.

* *Engineering*, June 8, 1888.

portion, as the consumers are more numerous, the defect of the system in this respect becomes more serious. A recording transmission dynamometer would of course, obviate the difficulty, but the cost of such an appliance is considerable.

It is, in some cases at any rate, a defect of the cable system that the amount of power which it is practically possible to transmit by a single cable is limited. It is not possible by increasing the size of the cable to transmit an indefinitely large amount of power. The cables became too heavy to be manageable, and the pulleys too large in diameter. In the report of the experts advising the town of Geneva, in 1889, the limit for one cable was placed at 100 h.p.; Messrs. Rieter Bros. place it at 300 h.p., and that amount has in fact, been transmitted; no doubt the proper limit varies in different cases.

It is also an inherent characteristic of the cable system that the efficiency decreases rapidly when the distance increases beyond certain moderate limits. On the most favourable interpretation of the experiments the efficiency may be ·96 for 100 yards or 93 for 500 yards, efficiencies remarkably high. But the efficiency falls to 0·60 for 5,000 yards, an efficiency by no means remarkably good.

LECTURE IV.

Hydraulic Transmission.

The practical application of a system of distribution of pressure-water for motive power purposes is due to Lord Armstrong. From the first, Lord Armstrong contemplated a distribution of pressure-water in town areas for the supply of motive power to many consumers. For that purpose the supply of water for motive power purposes may be conjoined with the supply of water for other purposes, the motors being driven by water from the ordinary town mains. In that case no special system of mains for power water is required; but, on the other hand, the pressure is limited to that suitable for ordinary water supply. Or a special system of distribution of power water may be adopted, and in that case it generally proves to be convenient and economical to use a much higher pressure than would be suitable for ordinary water supply. For a long time the installations carried out for the hydraulic distribution of power were of a local and restricted character, and were special systems of the latter kind. Only in a few towns pressure-water for a small number of motors was obtained from the ordinary mains, the price charged for the water being so great that it was preferable, in most cases, to use steam or gas engines.

The advantages of hydraulic transmission for actuating machines which work intermittently, such as cranes, lifts, capstans, and dock gates, were soon obvious. For this particular purpose, it is convenient to use exceptionally high pressure with small mains and comparatively small motor cylinders. Such high pressure hydraulic transmissions were first erected in connection with docks and arsenals. It was only after many years that similar systems came to be applied for power supply over extensive town districts. The conditions under which high pressure systems first achieved success gave them a special character, which imposes definite limitations on their application. The high pressure system is almost exclusively an English system and almost exclusively suitable for working intermittent machines. For ordinary power purposes it is less well adapted. Comparatively recently systems of hydraulic transmission at more moderate pressure have been carried out which are better suited to distribute power for ordinary industrial purposes.

In driving cranes and other intermittently-working machines the fluctuation in the demand on the mains for pressure water is very great. Hence, in developing his system, Lord Armstrong was led very soon to consider the question of the storage of energy. Reservoir storage for systems in which the pressure is very great is not generally possible, because no site sufficiently elevated can be found for the reservoir. Air vessels were considered, but the amount of energy which can be stored in that way is not very great, and there are practical difficulties. The pressure in the air vessel varies with the quantity of water in store, and an air pump must be used to replace the air absorbed and to maintain the air cushion. The invention of the accumulator met the difficulty. The accumulator perfectly answers the purpose of storing such a supply of water under pressure as is required to meet the momentary fluctuations of demand in a system driving intermittent machines.

In an article in the *Mechanics' Magazine*, in 1840,* very interesting now, if its date is considered, Lord Armstrong pointed out that when water is lifted by a pumping engine, it becomes the recipient of the energy expended in raising it. If the same water is used to actuate motors, it renders back the power conferred on it in its descent to its original level, and thus becomes a medium through which the power of the pumping engine may be transmitted to a distance and distributed in large or small quantities as required. Lord Armstrong showed that a continuously working steam pumping engine, of comparatively small size, was capable of doing a large amount of distributed intermittent work, and he argued that this would be more economical than the employment of a number of steam motors to drive each separate machine.

Soon after this, Lord Armstrong invented an hydraulic crane of a type used ever since. The pressure-water acts on a piston, the motion of which is multiplied by reduplicating a chain over pulleys. In 1845 a crane, worked by pressure-water from the town mains, was erected in Newcastle; and in 1848 similar cranes were used by the North-Eastern Railway at their goods station in Newcastle. In 1851 hydraulic transmission was adopted for driving cranes and working dock gates at Great Grimsby, at New Holland, on the Humber, and by Brunel on the Great Western Railway.

(To be continued.)

PHYSICAL SOCIETY.

At a meeting of this society, on the 27th ult., Prof. J. Perry, F.R.S. (vice-president) in the chair,

Mr. E. C. Rimington read a paper "**On the Behaviour of an Air-Core Transformer when the Frequency is Below a Certain Critical Value.**" Taking the ordinary differential equations for two circuits having self and mutual induction, and assuming sinusoidal E.M.F.'s and constant coefficients, the author shows that although the difference of phase between the primary potential difference and primary current is always diminished on closing the secondary circuit, yet under certain circumstances this closing increases the impedance of the primary. With constant potential difference this means that closing the secondary decreases the primary current, a phenomenon not usually observed. The critical conditions necessary for increased impedance are fully worked out in the paper, as well as those under which this increase becomes a maximum. In the case of two identical coils with no magnetic leakage, the critical value of a ($a = \frac{p L}{r_1}$, where $p = 2\pi$ times the frequency, L the inductance of the primary, and r its resistance) is $\sqrt{2}$, whilst that to give maximum impedance is $\frac{1}{\sqrt{2}}$. The maximum increase possible is 15½ per cent. The corresponding values are given for various amounts of magnetic leakage in tabular form, and curves were exhibited at the meeting showing how the impedance, current, power, and magnetising effect vary for different values of a. To test his conclusions, the author made experiments on two coils close together, the observed increase in impedance amounting to 3·2 per cent. In addition to the analytical investigation, the subject is treated geometrically at considerable length. **Prof. Minchin** showed that the impedances might be represented by two hyperbolas, having p^2 as abscissæ and the squares of the impedances as ordinates. These could be readily constructed from the data given. A line representing the primary inductance drawn on the same diagram intersects one hyperbola, showing that the impedance has always a maximum value. By a simple construction the phase angle between the primary and secondary currents could be determined for any given conditions. **Dr. Sumpner** observed that increased impedance on closing the secondary necessarily meant a decrease in the lag of the primary current behind the primary potential difference. **Mr. Blakesley** was pleased to see the geometrical method of such service, and thought it much simpler than the analytical one. The reason why increased impedance on closing the secondary of ordinary transformers had not been noticed was because their lag angles were very large. In a figure published some years ago to represent the actions of transformers the angles he had chosen were such as would make the primary impedance increase on closing the secondary. Giving an expression connecting the primary currents on open and closed secondary respectively, he now showed that to get increased impedance the sum of the lag angles in primary and secondary must exceed 90deg. To get large power in the secondary the primary lag should be nearly 90deg., and the secondary about 45deg. He also pointed out that some of the figures in the paper might be simplified considerably. **Prof. Perry** said he had long had the impression that if a sufficiently small current were taken from the secondary, increased impedance would be observable in all cases, and he quoted some numbers he had given in the *Philosophical Magazine* for 1891, showing a decided increase. **Mr. Rimington**, in reply, said he was not aware that the effect he had now brought forward had been observed previously. The result was completely worked out analytically before using geometrical methods.

Mr. W. B. Croft, M.A., showed an experiment on "**Electric Radiation in Copper Filings,**" similar to those described by Dr. Dawson Turner at the Edinburgh meeting of the British Association. A battery, galvanometer, and glass tube containing copper filings were joined in series. Under ordinary circumstances no current passed, but immediately an electric spark was produced by an electric machine many feet away the galvanometer was violently deflected, and remained so until the tube was tapped. On trying different materials, aluminium and copper seemed about equal, but iron not so good; carbon allowed the current to pass always. **Prof. Minchin** said the phenomena were strikingly like those exhibited by his "impulsion cells," for the moment a spark passed, even at a distance of 130ft., they became sensitive to light. Very minute sparks were capable of producing the change, but by adding capacity to the sparking circuit the effect could be greatly modified. Replying to a question from Mr. Rimington, he said the change was due to electromagnetic vibrations, and not to light emitted by the sparks. **Mr. Blakesley** enquired if lengthening the sparks produced greater effect on the copper filings. **Mr. Lucas** asked if the resistance of a tube ever became infinite again if left for a long time. In reply, **Mr. Croft** said the current sometimes passed before the spark actually occurred between the knobs. He had not left tubes for very long, and had not found the resistance reappear without tapping.

LEGAL INTELLIGENCE.

FRY AND FRANCIS v. ST. JAMES'S AND PALL MALL COMPANY.

Mr. Justice Kekewich on Wednesday heard the action of Fry and Francis v. the St. James's and Pall Mall Electric Light Company, Limited, the question raised being whether the company, under its articles of association, was justified in carrying over from profits £1,000 in each of two years to a fund called the redemption fund, to the detriment of the founders' shares issued by the company. The plaintiffs (Mr. Charles Robert Fry and Colonel George Edward Francis) held, the former two and the latter 10 founders' shares, besides being ordinary shareholders, and they sued on behalf of themselves and the other holders of founders' shares in respect to the distribution of profits, to one-half of which they were entitled. For the year ended December, 1890, a dividend was paid at the rate of 5 per cent., a sum not sufficient to enable founders' shares to come within the distribution; but at the end of 1891 8½ per cent was paid on the ordinary shares, and the holders of founders' shares each received £10. 15s., representing one-half of the surplus profits for the year, and in 1892, besides satisfying the preference shares, 7½ per cent. was paid to the ordinary shareholders and eight guineas to each founders' share. The directors, however, in each of these years carried over from profits £1,000 to a redemption fund, as plaintiffs said, to the detriment of founders' shares, and in favour of the ordinary and preferential shares. The point was, were they justified in so setting aside this sum?

The case for the plaintiffs was argued by Mr. Renshaw, Q.C., and Mr. Whinnie, and for the defendant company by Mr. Warmington, with whom was Mr. Swinfen Eady, Q.C. Their contention was that there was no imputation of *mala fides* on the part of the directors, who had acted on the advice of most experienced persons and in the ordinary conduct of the business of the company. Unless their *bonâ fides* were disputed and a question of *ultra vires* was raised, plaintiffs had no *locus standi*, besides which the directors asserted that the memorandum of association authorised them to act as they had done.

In the result, his **Lordship** said that the point raised in this case was a new one, and raised for the first time, founders' shares being a modern invention, and not yet having attained any technical meaning. The *bonâ fides* of the directors were not impugned, and if it were a question of internal management, according to well known principles and decisions, the Court would certainly not interfere with what the directors had done. They were removable representatives of the shareholders, and entitled to manage the business of the company to the best of their ability. This was not a question of the power of the directors, but one of contract, based on the memorandum of association, and he thought he was bound to hold the holders of founders' shares to be parties to those articles. He could not think their provisions operated to shut the mouths of holders of founders' shares in the way suggested. If their mouths were not so shut, the accounts showed that something of the net profits of the undertaking had not been divided, and ought to have been divided. Such being his construction of the contract, he considered the plaintiffs entitled to the claim they made, and he gave judgment for them accordingly, with costs against the company.

HOERLER AND ANOTHER v. HANOVER CAOUTCHOUC AND TELEGRAPH WORKS.

In the Queen's Bench Division on Tuesday, before Mr Baron Pollock and Mr. Justice Kennedy, the case of Hoerler and Another (trading as C. F. Mumm) v. Hanover Caoutchouc, Guttapercha, and Telegraph Works, was heard. This case raised one of those questions so often arising as to the mode of suing foreign firms carrying on business in this country, but having no place of business in this country. The parties had in June, 1890, at Linden, near Hanover entered into a contract in writing, in which it was stipulated that Mumm should receive a commission of 5 per cent. "on all remitted net amounts" of invoices on the sale of goods of the Hanover Guttapercha Company, to be accounted for every six months, but by a supplemental article, the Hanover Company were "to collect the accounts." The plaintiff's firm carry on business in this country, and the sales were here, but one of the articles of the contract was, "In case of disputes, the firm of Mumm submit to the laws in force in Hanover, and jurisdiction." The action was for the stipulated commission on sales of the Hanover Company's goods by the plaintiff in this country. The history of the litigation which had already taken place was this. The original writ in the action, an ordinary writ of summons without leave to serve it out of the jurisdiction of this Court, was issued in February last. It was served on some one who was deemed an agent of the defendants, the Hanover Company, in Basinghall street. On March 20 an application was made to a judge at Chambers to set aside the writ and service, on the ground that the Hanover Company had no place of business in England, and on the affidavits it was held that the company had no place of business in this country, and consequently the writ and service were set aside. On May 2 an application was made to amend the writ, and make it one for service out of the jurisdiction, and Mr. Justice Mathew having made the order at Chambers, the writ was served at the company's place of business in Hanover. On June 5 an application was made at Chambers before Mr. Justice Wills to set aside the proceedings on the ground that there was no cause of action in this country (the commission not being payable here), and that the special clause in the contract gave exclusive jurisdiction to the Court in Hanover. The learned judge set aside the proceedings on this latter ground, but Mr. Justice Collins had subsequently allowed time to appeal, considering, he said, the point to be one of importance. Mr. Temple Franks appeared on the part of the plaintiff, who appealed, and argued in support of the order to proceed in this country, and urged that the goods were sold and the commission earned in England.

Baron Pollock, in giving judgment, said the main question was one of importance, and required to be decided with consideration — viz., that there being no breach of contract within the jurisdiction of this Court, there was no liability in the foreign firm to be sued in this Court. The decision of the Court of Appeal, however, in "Reynolds v. Coleman," 36 Chancery Division, completely covered this case, it being held in a similar case that the service out of the jurisdiction ought to be allowed when according to the terms of the contract, it ought to be performed in this country. That, he thought, was the true rule, and it applied in the present case. This was a contract with a foreign firm for money to be paid to plaintiff for commission to be earned by him in England. The action was brought for the commission, and there could be no doubt it would be a fit case for service out of the jurisdiction, apart from the clause in question as to jurisdiction. That clause provided that the parties should submit to the laws and jurisdiction of the foreign country. If it had been intended to give the Court in Hanover exclusive jurisdiction it might have been so provided in express terms but it had not been so provided, and it appeared enough to hold that it was intended simply to provide that the parties should not be precluded from the Court in Hanover. That being so, he held that the action might be brought in this Court, and, therefore, that the process ought not to be set aside.

Mr. Justice Kennedy concurred, and observed that the contract was one which, according to its terms, ought to be carried out in England, on the ground that the money would be payable there. On the main question the clause in question was only that the parties would submit to the laws and jurisdiction of Hanover — that is, that the plaintiff would not object to the jurisdiction of Hanover. Judgment, therefore, was given for the plaintiff.

COMPANIES' MEETINGS.

INTERNATIONAL OKONITE COMPANY, LIMITED.

An extraordinary general meeting of this Company was held at Cannon street Hotel on the 27th ult. to consider, and, if thought fit, to pass a resolution to the effect: "That the name of the Company be changed to 'The Okonite Company, Limited'"; to consider and, if thought fit, approve draft alterations in the articles of association of the Company; and to consider and, if thought fit, to pass a resolution to the effect: "That the articles of association, as altered and approved by this meeting, and for the purpose of identification subscribed by the chairman thereof, be, and the same are hereby, approved, and that such regulations be, and they are hereby, adopted as the regulations of the Company, to the exclusion of all the existing regulations thereof."

Mr Samuel Pope, Q.C., who presided, explained that the meeting was convened by the Directors in response to the request of a large body of the shareholders of the Company. At the last general meeting the Directors expressed considerable hope that they would be able so to arrange the business at the Manchester factory that it might be turned from a losing into a profitable concern. They did their best, but they found that in order to put it on a sound footing it would be necessary to appropriate a certain amount of working capital to that department of the business. The branch in America was being conducted at a considerable profit, but the revenue made there was liable to be depleted by any losses which occurred in carrying on the business on this side. That fact and the general financial situation in America had induced both the American and English boards to reluctantly come to the conclusion that the proper course to adopt, if the Manchester factory could not be worked profitably, was to cease business in England. He could not say absolutely, but almost the whole of the English liabilities had been arranged, and the property of the Company here was practically unencumbered. The effect of the amendments to the articles of association would be that the existing Board in England would cease; but a certain number of directors would be elected to study the interests of shareholders in this country. The Chairman concluded by moving the resolutions given above.

Mr. Short, the representative of the American Board, seconded the motion, and explained the methods of the Company in America, and described the effect of the present financial crisis. If the amendments were passed the Company could, he thought, be made a success.

Mr. Shaw moved the following addition to the first amendment—namely, Article 35: "Provided that the funds of the Company should not be expended or lent upon the purchase of its own stock."

Mr. Clements, the agent for the American shareholders, said he held proxies for more than 16,000 shares, and his instructions were to vote only for the amendments as proposed.

Mr. F. L. Rawson objected *in toto* to the amendments being

passed, as the measure would place the Company entirely at the mercy of the American shareholders. It was necessary that it should be carried with a three-fourths majority, and he felt certain that if shareholders on this side were consulted more than the requisite fourth could be obtained to defeat the project. The Americans would then be more disposed to reconsider the first amendment to the article.

Mr Shaw's amendment was seconded and supported, there being a very strong expression of opinion as to the advisability of passing the amendment to Article 35 as proposed. At the invitation of Mr. Clements, however, who undertook to represent everything fairly to the American shareholders, Mr Shaw withdrew his opposition, subject to his right, through Mr. Clements, to forward his reasons to the proper quarter in America. The latter gentleman also engaged to send to America any other objections that might reach him.

The resolutions were then put and carried with a few dissentients.

EASTERN EXTENSION TELEGRAPH COMPANY.

The fortieth ordinary general meeting of the Eastern Extension, Australasia, and China Telegraph Company, Limited, was held on Wednesday, Sir John Pender presiding.

In moving the adoption of the report and accounts, the **Chairman** stated that the gross revenue for the half year ended June 30 last had been £257,980, or £10,998 in excess of that of the corresponding period of 1892; while the working expenses had been £78,229, showing a decrease of £1,052. The usual interim dividends at the rate of 5 per cent. per annum had been paid for the past half year, amounting to £62,500, and the balance of £81,116 had been carried forward, as against £70,271 for the corresponding period of 1892. The second year of the Australian tariff guarantee arrangement expired on April 30 last, when it was found that the loss for the year had been £43,558, as compared with £55,040 for the first year of the guarantee. One half of this loss, or £21,779, had been made good by the guaranteeing governments, and the remainder had been distributed between their Company and its partners in the pool. During the current or third year of the guarantee the loss would, as far as they could at present judge, be comparatively nominal, owing to the additional 9d. that was added to the tariffs at the request of the colonies having come into force January 1 last, and to the abnormally large traffic that was carried a few months ago when the bank reconstruction schemes were being arranged. With regard to the cable recently laid by a French company between Queensland and New Caledonia, its promoters claimed for it that it was the first link of the much talked of Pacific cable between Australia and Canada. It had been laid under a guarantee arrangement with the Governments of France, Queensland, and New South Wales, the two colonies giving a subsidy of £2,000 a year each, and the French Government giving a guarantee of something like £8,000. After the strong opposition which had been displayed to this cable, both in the colonies and on this side, it was not likely to be anything more than a local line, and as a local line it ought to be a small feeder to this Company's system. He might mention a fact which should be a lesson to those who had no experience of cables, and it would afford such persons the opportunity of learning from those who had such experience. Only last week both of the Company's Port Darwin cables became interrupted within a few hours of each other, many hundred miles apart, and but for their third cable to Western Australia the colonies would have been entirely cut off from telegraphic communication. Fortunately, they had a repairing vessel available close by, and within a few days they hoped that both cables would be repaired; but similar troubles, arising from inequalities of the bottom and from coral landing places, would most certainly occur in the Pacific, making it absolutely necessary to provide a duplicate line, with at least two maintenance ships and a large sinking fund obtained from earnings, to replace the cable within a reasonable period. Negotiations had been in progress for a good many years for strengthening the China section of the Company's system, and with this object they had for the last 10 or 12 years been working not only with the Colonial Office but with the Straits Government and Hong Kong. They had endeavoured to obtain a concession with some subsidy for the work they proposed to do.

The motion, which was seconded by the **Marquis of Tweeddale**, was carried unanimously.

MONTEVIDEO TELEPHONE COMPANY, LIMITED.

The annual general meeting of this Company was held on Tuesday at the offices in Gresham House, Old Broad street, E.C.

Mr. Herbert Ward presided, and, in moving the adoption of the report, said that during the year ended July 31 last their net profits amounted to the sum of £6,895, which was about £500 more than the net profits of last year; but it must be remembered that last year's profits showed an increase of £1,622 over the previous year; so that there was no doubt that the Company's operations in Monte Video continued to make satisfactory progress, notwithstanding the prevailing hard times in Uruguay. The strictest economy had been observed in all matters relating to the general working of the Company. The central office building in Monte Video had now become the unencumbered property of the Company, the last instalment of the purchase-money having been paid on March 6 last, since which time they had received regular monthly drafts from the manager. One of the Directors had only just returned from Monte Video, and he was thoroughly satisfied with the manner in which their business was conducted by the manager and his staff, and also with the condition of the Company's property. The number of paying subscribers was now 1,383, showing an increase for the year of 33, and with a return to more normal conditions in commercial circles generally in Uruguay, there was no doubt that number would be substantially increased. The Board had to announce that the committee of the London Stock Exchange granted, on June 12 last, an official quotation to the Company's preference and ordinary shares.

After **Mr C. H. Sandford** had seconded the motion, a long discussion followed, in the course of which **Mr. Lock**, **Mr. Touch**, and **Mr. Praed** found fault with the Directors for not declaring a dividend on the preference shares out of the profits that had been earned, as was done on the last occasion, instead of placing the same to the reserve and depreciation fund.

The **Chairman** stated, in reply, that the Board had been informed that it was illegal to declare a dividend on the preference shares at present.

After some discussion **Mr. Touch** moved an amendment to the effect that the report and accounts be referred back to the Board, in order that they might recommend a dividend of 3 per cent. to the holders of the new accumulative preference shareholders of the Company, they agreeing to lend the amount until the Company was in a position to repay the same, with interest.

The amendment was seconded and lost. A poll was demanded, which resulted in the amendment being negatived and the report adopted. After the re-election of Mr. E. F. Powers, Mr. Jones was elected a director of the Company.

BUSINESS NOTES.

Church-Lighting.—The church of St. Mary at Hill, City, is to be lighted electrically.

Western and Brazilian Telegraph Company.—The receipts for the week ended October 27 were £3,704.

Club Lighting.—The question of lighting the Liverpool Junior Reform Club by electricity is being considered.

Eastern Telegraph Company.—The receipts for the month of October were £61,402, as against £61,069 for the corresponding period.

Queenstown.—The Public Commissioners will shortly have brought before them by a company the question of lighting the town by electricity.

Eastern Extension Telegraph Company.—For the month of October the receipts show a decrease of £1,899 as compared with the corresponding period.

South Africa.—At the Crown Reef the erection of the new 120-stamp mill, of the cyanide works, and of the electric lighting plant is being pushed on with despatch.

Blyth.—A large hotel has been opened in Northumberland-street by the Blyth and Tyne Brewery Company, Limited. It is fitted with speaking tubes and electric bells.

Windsor.—New wires have been laid between the Queen's private telegraph office at Windsor Castle and the borough post office at the corner of High street and St. Albans street.

Castleford.—Mr R. Hammond is to advise the Local Board as to the best means of lighting by electricity, preparing plans, and doing the work to the time of applying to the Board of Trade.

Ipswich.—The petition for the winding up of the Ipswich Electricity Supply Company, Limited, referred to in our issue of the 20th ult., has been adjourned to allow of a meeting of creditors.

Office-Lighting.—Messrs. Drake and Gorham have contracted for the electric lighting of the Rock Life Insurance Company's offices, New Bridge street. There will be 120 lamps of 16 c.p. installed.

Gloucester.—The seal of the County Council has been affixed to an agreement for providing telephonic communication between certain police stations near Bristol and the Bristol telephonic exchange.

Measuring Instruments.—Messrs. Paterson and Cooper have been appointed agents for the sale of Messrs. Richard Freres' electrical and industrial measuring instruments for the United Kingdom.

English Electric Manufacturing Company, Limited.—This Company has been registered with a capital of £5,000, in £1 shares, to carry on business as electricians, electrical and mechanical engineers.

Anti-Sulphuric Enamel.—The "anti-sulphuric" enamel made by Messrs. Griffiths Bros. and Co. is being employed in the central station at Brussels for the protection of metal and woodwork from acid fumes.

Manchester.—The subject of lighting the Assize Courts by electricity has recently engaged the attention of a committee of the County Council. For the present, however, it is considered advisable to continue the use of gas.

Trade Dispute.—With reference to the note on this subject in our last issue, it is stated that the two men arrested on a charge of wilfully removing the fuses connected with electric light installation at the Medley Hotel are not connected with the Electrical Trades Union.

Caldbeck.—The Post Office having decided to erect a new line of telegraph wires from Penrith to Wigton, Annan, etc., the villagers of Caldbeck and Sebergham are making an effort to have telegraph stations established on the line of route.

Elmore Wire Company.—At the invitation of the directors, a meeting of the largest shareholders of the Elmore's Wire Manufacturing Company, Limited, was held last week at Winchester House, E.C. The proceedings were private.

Extension of Premises.—It is satisfactory to note that owing to the rapid increase in Messrs. Drake and Gorham's business, they have found it necessary to extend their offices, as their present accommodation is entirely inadequate.

Towcester.—The inhabitants have been canvassed as to whether they will adopt the electric light. Signatures have been obtained for about 800 lamps from the principal shopkeepers, and Sir T. G. F. Hesketh, Bart., of Easton Neston House, will require 100 lamps.

Partnership.—A gentleman with engineering or commercial experience is required to take an active part in an electric light syndicate in full work. The sum of from £1,500 to £2,000 is required. Applications to be sent to Mr. George Ashdown, 56, Gresham-street, E.C.

Tender Accepted.—The tender of Mr. C. Dennis, of Bury, has been accepted for the brickwork, boiler seats, etc., required in the fixing of two Lancashire boilers and one set of Green's economisers at the Lancaster electricity works, Morton street yard, for the Electric Lighting Committee.

City and South London Railway Company.—The receipts for the week ending October 29 were £848, against £889 for the same period last year, or a decrease of £41. The total receipts for the second half year of 1893 show an increase of £257 over those for the corresponding period of 1892.

Wrexham.—The electric light and power company are about to apply to the Board of Trade for a provisional order to authorise them to supply electricity for public and private purposes in the borough of Oswestry, and to do all the necessary work to supply the town with electric power and energy.

Electric and General Investment Company, Limited.—The directors have declared an interim dividend on the capital paid up on the ordinary shares of the Company at the rate of 10 per cent. per annum for the six months ending November 30, 1893, the dividend to be payable on and after December 1 next.

Meeting of Creditors.—At the London Bankruptcy Court on Tuesday, an adjourned meeting was held of the creditors under the failure of Messrs. Day and Young, mechanical engineers, of Bath and London, whose accounts show total liabilities £27,505, and assets valued at sufficient to provide a small surplus.

J and J Robertson, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to acquire the business of cycle manufacturers, makers of gas engines, and general machinists now carried on by William Robertson, James Robertson, and two others at Eccles, Lancashire, under the style of J. and J. Robertson.

Fulwood.—At a meeting of the Local Board the clerk read a letter relating to telephone communication with Mr. Jones, the water manager. The letter stated that the communication could be had for the low term of £13. 10s. per annum for three years. If they wanted the exchange they could have it for £23. The offer of £13. 10s. was accepted.

Canterbury Electricity Company, Limited.—This Company has been registered, with a capital of £50,000 in £5 shares, to carry on business as electrical engineers and electricians, manufacturers of electrical appliances, etc. The first signatories are B. Broadhurst, G. E. Zeden, F. E. Beeton, F. Hodson, W. D. Brightman, R. P. Sellon, and A. J. Lawson.

Newcastle.—The question as to the desirability of the Corporation providing electricity in the city is now under the consideration of a committee of the Council, composed of five members each of the Watch, Finance, and Town Improvement Committees. The new Church of England Institute in Hood street is being lighted electrically by Messrs. R. J. Charlton and Co.

Car Accident.—An electric car on the Oregon (Portland) City Tramway line, containing 30 passengers, went through an open drawbridge in Madison street on Wednesday, and was plunged into Carpon River. It is said that 25 of the occupants of the vehicle have been drowned. The car was the first to arrive in Portland from the suburbs, and a heavy fog was then hanging over the city.

Salford.—The minutes of the Gas Committee of the Corporation presented at a meeting this week, mentioned that the town clerk had received the official sanction of the Local Government Board to the borrowing of £32,000 for electric lighting purposes, repayable within 25 years. This amount represented the portion of the £50,000 applied for which it was proposed to expend in the first instance.

Dover Electricity Company Limited.—This Company has been registered by Mr. Sydney Morse, with a capital of £50,000 in £5 shares, to carry on the business of electrical engineers, electricians, engineers, and contractors, suppliers of electricity, and manufacturers of electrical apparatus. The first signatories are B. Broadhurst, G. A. Zeden, F. Hodson, F. E. Beeton, R. P. Sellon, W. D. Brightman, and A. J. Lawson.

Tenders for Bolton.—Tenders are wanted by the 18th inst. for the supply and erection of switchboards, accumulators, connections, etc., for the Gas and Lighting Committee of the Bolton Corporation. Specifications, plans, and forms of tender may be obtained on application to Mr. J. H. Rider, M.I.E.E., borough electrical engineer, Town Hall, Bolton, on payment of £1. 1s., which sum will be returned on receipt of a *bona fide* tender.

Govan.—The Govan Combination Parochial Board met the other day. With regard to the lighting of the new asylum at Hawkhead, a report was submitted which showed that electricity would cost per annum £635, oil gas £282, and Glasgow Corporation gas £200. These figures indicated the total cost, including interest on the price of plant, etc. It was unanimously agreed to adopt the recommendation of the Lunacy Board and light the building with Corporation gas.

Halifax.—At a special meeting of the Town Council it was mentioned that the Gasworks Committee had instructed the town clerk to write to the Local Government Board regarding the application of the Corporation for sanction to borrow £30,000 for electric light works, and to urge the necessity of an early decision. The Gasworks Committee have adopted the proposal of Mr. W. H. D. Horsfall, architect, to prepare plans, etc., for the proposed electric light station.

Burnley.—At a meeting of the Town Council last week Councillor C. Thornber, wished to know if there was any necessity to fix the electric light in the baths? Councillor Lupton replied that it was frightfully hot at night when the gas was lit, and particularly on gala nights. Alderman Burrows said that the electric light had been put throughout the municipal buildings, and now there was an outcry because the working classes were to have a little of the benefit. The motion was passed.

Dewsbury.—The Board of Trade has approved of the system adopted by the Council for the supply of electrical energy for the purposes of the Dewsbury Electric Lighting Order, 1891, subject to the regulations and conditions for securing the safety of the public, and for ensuring a proper and sufficient supply of energy. The site of the old gasworks at Batley Carr is to be used for the erection of the station. Sanction has been received from the Local Government Board for the borrowing of £25,000 for electric lighting purposes.

Chatham.—At a meeting of the Kent Standing Joint Committee at Maidstone, Mr. C. R. Chelfins reported that Chatham police station had now been connected with the telephone, and that the cost would be £10 a year. This was approved of, but an application for the Seabrook lock up to have similar communication with Hythe police station was not entertained, the county surveyor stating that the telephone company not having yet erected a wire between those two places, the cost of a private wire would be a considerable amount.

The Luna Arc Lamp.—An instance of high-tension series arc lighting by a gas engine can be witnessed at the Agricultural Hall where 40 of the Electrical Company's Luna arc lamps are lighting the main hall of the above institution. The current is being supplied by a 50 h.p. Stockport gas engine, driving a Brush high tension dynamo. This is one out of many successful installations carried out by Messrs. Vaughan and Brown, who submit that the Luna lamp is more simple and reliable, and equal in quality to any of its competitors. The price of the lamps is low.

Kensington.—A joint report on electric lighting has been presented to the Special Lighting Committee of Kensington Vestry by Major General Webber, C.B., R.E., and Mr. Philip Monson, the lighting engineer. In accordance with the recommendations therein contained, the Vestry have instructed the solicitor to issue the formal notices in respect to the application in the next session of Parliament for a provisional order to lay down plant, light the streets with electricity, and supply electricity for domestic and other purposes. Notifications were received at a meeting of the Vestry last week for the extension of the mains of the Notting Hill and Kensington Electric Lighting Companies.

Taunton.—The Electric Light Committee of the Town Council reported last week as follows: "Your committee present herewith statement of account showing the sum of £9,716. 8s. 10d., due to the electric light company out of loans account, and £133. 4s. 11d. out of revenue account, making together £9,849. 13s. 9d., after deducting interest at 4 per cent. upon the amount expended by the Council upon the mains. They also present three cheques in discharge of these several amounts—viz., debenture-holders, principal and interest, £7,407. 15s.; electric lighting company, £2,308. 13s. 10d.; out of revenue account, £133. 4s. 11d.; a total of £9,849. 13s. 9d., which they asked the Council to sign." The report having been adopted, the town clerk read out the document by which the property was conveyed from the company to the Corporation, and the seal of the borough was affixed thereto.

Monmouth.—The Mayor remarked at a meeting of the Town Council last week that he had visited London a few days ago and took occasion to call upon the Local Government Board, with the engineers for sewage and electric lighting. Mr. Lailey and the Brush Electrical Company undertook to forward their estimates to him (the mayor), and he had received them by that morning's post. He had no time to go through them very much to be able to give them an epitome of the contents. The object of that meeting was to receive and discuss those estimates, to move a resolution upon them, and if they (the Council) accepted them to make application to the Local Government Board to authorise them to borrow the money. The matter was then discussed in committee, and ultimately the Council decided to apply to the Local Government Board for sanction to borrow £18,000 for the purpose of carrying out the sewerage scheme and electric lighting.

Hawick.—At ward meetings last week one of the subjects discussed was the question of lighting the town with the electric light. The scheme put before the electors was drawn up by Messrs. Mavor and Coulson, of Glasgow, and proposed that the water power at Trowmill, about two miles from the town, should be utilised. The scheme includes the raising of the Cauld by 8in., the erection of a power station and turbine wheel which would develop 100 h.p., which, if found necessary, could be doubled by transferring the plant to Hornshole, about half a mile farther down the river. The estimated cost of the scheme for lighting the entire town, with extension to Town Hall, police office town clocks, stables shambles, sewage works, etc., is given at £9,250 and the annual cost at £835. The cost of lighting by gas at present is given at £841. No decision was come to at any of the meetings, the matter being left in the hands of the representatives for further consideration.

Aluminium Company.—In their report for the 12 months ended June 30, the directors state that the hopes they ventured to express in the last annual report, that a time of greater prosperity for the Company was at hand, have not been disappointed. The Oldbury trading account shows a profit of £7,244 19s. 11d., but this amount was not quite sufficient to meet all fixed charges at the head office, including debenture interest. The volume of the Company's business has increased very rapidly during the last few months, so as to promise a much more favourable result for the current financial year. The directors think this a suitable time to rearrange the capital, and at the extraordinary meeting a resolution will be proposed to write off £4 per share, thereby reducing the nominal value to £1 per share. The directors believe that the present income of the Company will be sufficient to meet all fixed charges, to provide adequately for depreciation, and to leave a balance for dividend on the reduced share capital.

Tenders for Sunderland.—As mentioned in our last issue, the Corporation invite tenders by the 17th inst. for carrying out the work comprised in any or all of the following contracts: (1) Lancashire boilers. (2) High-speed compound engines, dynamos, pumps, steam and other pipes, etc. (3) Motor alternators switchboard, etc. (4) Main switchboard instruments, and connections. (5) Batteries. (6) Insulated cables, etc. (7) Roadwork (*a*) construction of culverts, laying of cast-iron pipes and casings, and building service boxes; (*b*) supply of cast-iron pipes casings, and service box frames and covers; (*c*) supply of stoneware casings and insulators. (8) Copper strip. (9) Gunmetal grip boxes. Those desirous of tendering for any of the above contracts must send in their names and addresses to the borough engineer, Town Hall, Sunderland, and copies of drawings, specification, and form of tender will be forwarded to them on receipt of cheque or order for £2 2s., which will, however, be returned on their submitting a *bonâ fide* tender.

Aberdeen.—A special meeting has been held to consider a proposal which has been made to light Castle-street and Union-street by electricity, the area to extend from the top of Justice-street to Union Bridge. It was decided that eight arc lamps would be sufficient to light the area. The proposal is that the lamps should remain lighted till midnight each evening, after which time the ordinary street lamps would be employed. The plant has already been laid in connection with the installation for the supply of electric light to shops and houses in the central area of the city, and thus no extra expense will be entailed. Mr. Smith, gas manager, will prepare an estimate of the cost of the eight lamps, while Mr. Anderson will furnish a statement as to the quantity of gas that will be saved, in order to show the difference between the two systems. The central electric lighting station will be ready in about six weeks. The experiment will afford an idea of what it would cost to light the whole city by electricity, and will also show the difference in the illuminating power of electricity and gas. The lamps will be placed on ornamental iron pedestals, and none of the existing street lamps will be interfered with in the meantime.

Grimsby.—The Mayor, in consequence of a letter which had been received from Mr. Hammond, moved, at a meeting of the Town Council last week, that an interview with that gentleman should be arranged. The letter having been read, the Mayor said that he was in possession of some information respecting Mr. Hammond by observing some work of his. He had received an invitation from the Mayor of Blackpool to be present at the installation of their system of electric lighting. At Blackpool they had spent £27,000 in the installation although they owned the gas works. He was thoroughly convinced of the practicability of the light. The reason why he should like Mr. Hammond to come and give his views on the question was that he had carried out hundreds of thousands of pounds' worth of work. It was necessary that they should move in the matter in some form. One of the conditions of the order would make it advisable that they should state where the centre or station would be placed, the size of the site, and the streets through which they proposed to lay the mains. It would be a wise policy to have an interview with Mr. Hammond. He proposed that they have such an interview. Mr. Alward seconded the proposition, and after some further discussion the motion was agreed to.

Sale of Plant.—On Friday, 17th inst., Messrs. Wheatley Kirk, Price, and Goulty will sell by public auction on the works premises, the entire contents of the Vulcan Ironworks, Beccles, Suffolk, together with the freehold land and buildings thereon. The fixed and loose plant will include Cornish boiler, 12ft. by 3ft. 2in. diameter; 4 h.p. vertical steam engine; 3cwt. steam hammer, three smiths' hearths, punching and shearing machine, 6ft. plate-bending and 3ft. sheet-bending rolls, fan, 36in. centre wheel lathe; 5½in., 10in., and 14in. centres slide; surfacing and screw-cutting lathes on 6ft., 14ft., and 16ft. beds; 14in. stroke shaping machine, and drilling machines. The new stock and stores will include steel boiler plates, boiler and steam tubes, brass boiler and engine fittings, castings, 6 h.p. portable engine by Garrett, 10 h.p. compound tandem portable engine by Vulcan Company, 2 h.p. vertical engine and boiler, 6 i.h.p. vertical steam engine, 9 i.h.p. vertical steam engine and tubular boiler on foundation tank, 9 i.h.p. and 17 i.h.p. tandem compound engines unfinished, two 6 i.h.p. tandem compound vertical engines, etc. Catalogues and any further information may be obtained at the works, or on application to Messrs. Wheatley Kirk, Price, and Goulty, 49, Queen Victoria-street, London, E.C.

St. Helens.—Alderman Cook, in moving the adoption of the Gas Committee's minutes, at a meeting of the Town Council on Monday, said the Council would observe that the committee recommended the making of an application for a provisional order for the supply of electric light to the borough for public purposes. Their object was to be prepared to take the matter up at the moment it was required. Colonel Gamble wanted to know if the Council would have an opportunity of expressing an opinion as to the area to be supplied by the Corporation. The Town Clerk said the compulsory area would have to be settled by the committee for the advertisement. The present area suggested was Corporation-street, between Hardshaw-street and Shaw street. Mr. Mearns complained of the bad gas. The Corporation had negotiated for 300 tons of coal from some firm at a price not stated. He hoped at the end of the financial year the Gas Committee would remember that the consumers were paying the same price for bad gas as they had hitherto paid for good gas, and that when the provisional order asked for was obtained that electricity would be at once introduced into the borough. Alderman Cook said he did not think the new plant at the gasworks would clash with the electric light, and in reference to the quality of the gas admitted that it was not as good as usual, but it was as good as they could secure in the present state of the coal market.

The Factory Acts.—On Wednesday, at the South Western Police Court, Mr. Denman heard three summonses against the New Electric Light and Power Company, Wellington-road, Battersea, for failing to register the names of young persons employed and to obtain certificates of fitness, and also for obstructing one of her Majesty's inspectors in the execution of his duty. Mr. Jasper Redgrave, one of her Majesty's inspectors, who conducted the prosecution, in answer to the magistrate said he had not summoned the official who was guilty of the obstruction, as the company, in the capacity of occupier of the premises, were responsible for the acts of their servants. The manager refused to permit an examination of the young persons to take place. The inspector so obstructed was called, and said the manager told the lads not to answer his (witness's) questions, and directed them off the premises, adding that if he (witness) did not leave in three minutes he would have him put out. The manager also prevented him from getting near the boys. He told the manager that he would not allow himself to be intimidated. The manager, who was in attendance, regretted the misunderstanding with the inspector. The story, he said, had been exaggerated. The inspector rushed into the factory, and his conduct was such that it demanded an apology. He denied that any obstruction had taken place. Mr. Denman said unless the Factory Act was enforced the whole thing would be utterly worthless. He imposed penalties amounting in all to £10, with £1 7s. [illegible]

Edinburgh.—The Lord Provost's Committee recommended, at a meeting of the Town Council on Tuesday, that parliamentary powers should be asked for the acquisition of additional property adjoining the properties already acquired for the site of the central electric lighting station at Dewar place, and for the closing of a portion of St. Cuthbert's lane, and craved a remit to give it effect. The recommendation was agreed to. The Cleaning and Lighting Committee recommended, at the same meeting, that various streets should be lighted by electricity. Bailie Gulland took exception to the list of streets, and asked why George-street, for example, had not been included. Mr. Mackenzie said Prof. Kennedy proposed that George-street and the streets leading down to Princes'-street should be lighted with the electric light, but the Cleaning and Lighting Committee threw that over. He implored them to decide something soon, as delay was keeping the whole matter up. Mr. Jamieson said the Cleaning Committee had to decide how they could best allocate 130 lamps. Mr. Mackenzie suggested that the matter should be recommitted to the Lord Provost's Committee. It was no use sending it to the Cleaning and Lighting Committee. Bailie Steel protested against the Cleaning and Lighting Committee being blamed for the delay. It was only at their last meeting that they had a plan before them from Prof. Kennedy showing what streets he proposed to light with electricity. It seemed to be the Cleaning and Lighting Committee that was to be blamed all round for everything that went wrong in the town. After further discussion, a motion to approve of the report was adopted.

Tenders for Newport (Mon.).—The Electric Lighting Sub-Committee of the Corporation of Newport, invite, as mentioned last week, tenders for the supply and erection of certain steam-boilers, feed water heaters, economisers, pumps, mechanical stokers, forced draught apparatus, steam, exhaust, and water pipes, condenser tanks, steam engines, driving ropes, oil filter, alternators for incandescent lighting, dynamos for arc lighting, switchboards, instruments, arc lamps and lampposts cables, culverts, surface boxes, junction boxes, converters, converter-boxes, converter-cases, switches, fuses, meters, also day load

plant, to consist of semi-portable engine, alternator and exciter and switchboard for the equipment of the municipal electricity works of the county borough. The plan of buildings map, and specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. Robert Hammond, M.I.E.E., the consulting engineer to the Corporation, 117, Bishopsgate-street, London, E.C., on payment of £2. 2s., which sum will be returned on receipt of a *bonâ fide* tender. Tenders (sealed and marked "Tender for Electric Lighting") must be addressed to Mr. Albert A. Newman, the town clerk, at the Town Hall, and be delivered on or before Monday, the 20th inst. A new Constitutional club and concert-hall is to be erected on a site at the bottom of Stow-hill, Newport. It is proposed to warm the hall and club premises with hot water on the low-pressure system, and to introduce the electric light for the purpose of lighting. The architects are Messrs. Habershon and Fawckner, of Queen's-chambers, 41, High street, Newport; also of London and Cardiff.

Llandrindod Wells.—A special meeting of the Local Board was held last week to consider whether steps should be taken to establish a gasworks or a system of electric lighting for the district. Mr. Preece (of Messrs. Andrews and Preece, Limited) had made an inspection of the district with the view of explaining to the Board the feasibility of introducing the electric light. Mr. Preece said there would be no difficulty in respect to turning gas out at Llandrindod and replacing it with electricity. At Morecambe the electric light was worked by gas power from one central station, and in that town there was the same difficulty as at Llandrindod Wells—namely, the reduction of the quantity of lights required in the winter season. At Morecambe it cost ½d per unit to generate the light and distribute it into the consumers' houses, while the cost of steam power would be 2d per unit. He considered that few, if any, towns had such a favourable opportunity as Llandridod Wells for introducing the electric light. In answer to questions, Mr. Preece stated that the installation would cost about £2,000, exclusive of land or buildings and the cost of a provisional order. He thought they could charge private consumers about 14s. per lamp per annum, but in a place like that, where the number of lamps used fluctuated greatly, it would be better to have meters. He thought there would be no difficulty in obtaining a revenue of £700 a year. The public lamps could be lighted by electricity at about 15s. per annum. The probable expenditure was calculated, and it was thought that £400 a year would be sufficient to repay the capital and interest of money borrowed to provide the plant and the working expenses. The question was discussed whether a provisional order should be applied for in the next session of Parliament, and the matter was adjourned for further consideration.

Camberwell.—At a meeting last week of the Vestry, Mr. Phillips moved that a statutory meeting of the Vestry should be held on Wednesday, December 6, for the special purpose of considering, and, if approved, of sealing, or authorising to be sealed, a memorial to the Board of Trade for a provisional order under the Electric Lighting Acts, to supply electricity for public and private purposes in the parish of Camberwell, and that an electricity committee of 24 members be appointed. Mr. Wallace said that if the Vestry gave notice, they would be compelled to go on, either themselves or by contractor. The first stage of the installation would cost £50,000, and ere it was completed it would entail an expenditure of £100,000. He confessed he should like to be supplied with further proof of the dust destructor scheme, and he should certainly object to any cost being incurred other than that for the provisional order. Mr Etherington said that if they went to Deptford, where a large electric lighting company had been established under the best scientific authorities, they would find that it had proved a failure. Mr Coward observed that there were some boroughs, such as Bristol, where half the rates were raised from rating and half from investments such as that of the electric light. It appeared to him that they were just at the parting of the ways with regard to the electric light, and that they ought to seriously consider the subject from the point of view of public benefit and public profit. At present the Vestry paid to the gas company £12,000 per annum for street lamps, and about £2,000 for the lighting of various public buildings. Even if they only saved that £14,000, they would save a large amount of interest, and provide a fair sinking fund. Mr. Charles thought there ought to be enquiry before even the cost of the provisional order was incurred. The motion, after further discussion, was adopted.

Lighting at Newport.—The electric lighting of the borough of Newport is now within measurable distance. The stage now reached is that, as mentioned elsewhere, of inviting tenders for the equipment of the station, which is to be provided on land belonging to the Corporation in New Dock street, and also for cables, culverts, arc lamps, and lamp standards, switches, fuses, meters, and all the appliances for furnishing an electrical supply. Eighty arc lamps are intended to be provided for street lighting, of which 50 will be put down as an instalment, and for the home 10,000 incandescent lamps will be arranged for. Newport is to be equipped with the high tension alternating current system. The town is a large district with a scattered population. The cost of the initial instalment will be covered by a loan of £28,000, and only the western side of the borough will be dealt with. Prof. Robinson was consulted as to the idea of burning house refuse beneath the boilers, but he worked out the profit and loss against the use of the said refuse. Newport possesses power which might be utilised in the rapid flow and the great fall of the Usk, besides the power which might be obtained from the "head" of water descending from the higher to the lower reservoirs on the slopes of Twym Barllwm. The history of the undertaking by the Corporation to provide electrical energy for the borough extends back to the year 1889, when no fewer than three companies sought to obtain powers to supply Newport with electricity. The Corporation successfully overbore all these sanguine promoters by declaring its intention to do the thing itself, and in 1890 gave the usual notices by which, in the year following, the Board of Trade granted the provisional order. As soon as the Corporation were armed with this authorisation the sub committee of the Parliamentary and Improvement Committee set to work. Besides St. Pancras, West Brompton, Chelsea, Leeds, Bradford, Oxford, Bournemouth, and Blackpool have been visited. Mr. Robert Hammond has been chosen as the consulting engineer to the Corporation.

Shiplighting.—In connection with the refitting of the "Howe," it is satisfactory to learn (writes a correspondent) that the only part of the work given by the Admiralty to outside contractors has recently been successfully completed by an Edinburgh firm. To Messrs. King, Brown, and Co., of Rosebank Electric Works, was entrusted the work of completely renewing the electric light and gun firing circuits, as, owing to the limited time available, the dockyard authorities were unable to take the work in hand themselves. The "Howe" is lighted by means of 520 16-candle incandescent lamps, in addition to the usual yardarm reflectors, masthead, side and semaphore signalling lamps, cables also being led to four search light projectors; while the gun firing arrangements comprise electric circuits, with the necessary batteries and firing keys for the four 63 ton barbette guns, for the six broadside guns, and for five torpedo tubes. Over 120 men were employed by the contractors, the work being carried on continuously day and night till its completion, which was effected within the brief space of 10 weeks from the date of order. The experiment of placing such a contract with a private firm has, in this case at least, proved so satisfactory that the authorities contemplate taking the same course in connection with several other vessels at present refitting in Chatham Dockyard. A twin-screw steamer of 9,000 tons, built for the Atlantic trade of the International Navigation Company, has been launched from the shipbuilding yard of Messrs. James and George Thomson, Limited, at Clydebank, near Glasgow. The vessel, which was named the "Kensington," will be lighted throughout by the electric light, for which a complete installation of engines and dynamos has been fitted by the builders. The Admiralty have approved a proposal to fit Messrs. Evershead and Richards's engine-room telegraph in the battleship "Howe" for trial. A steel screw steamer, which has been built to the order of Messrs. J. M. Lennard and Sons, Middlesbrough, for the purpose of carrying petroleum in bulk, has been launched from Sir Raylton Dixon and Co.'s Cleveland Dockyard, Middlesbrough. The vessel is provided with the electric light.

Preston.—The proceedings of the Streets and Buildings Committee, presented at a meeting of the Town Council last week, set forth that, pursuant to resolution of the 2nd of October, the surveyor had submitted a plan of his suggestions as to proposed lighting by electricity of the portion of Church street from Lancaster-road to the gaol, and that the committee resolved that the gas lamps in Church street from Lancaster-road to the gaol be provided with 10ft. burners, and that six additional gas lamps be put down, and that in the meantime the consideration of the plan for electric lighting be postponed. Alderman Satterthwaite, in moving the adoption of the proceedings, said it was understood a year ago when they lighted Fishergate with the electric light that it was to be an experiment as to whether they were to extend it at any future time. The committee had given the matter their consideration, and they did not, as this recommendation said, see their way to recommend the extending of the electric lighting to Church street. They found that to light Church street in the same manner as Fishergate was lighted at the present time would entail an additional expenditure for the present of £112. The committee did not consider that the amount of light in Fishergate was worth that additional expenditure of money per annum. They considered that for an expenditure of between £30 and £40 additional they could get light more generally diffused, and which would enable passengers, both by foot and vehicle, to be illuminated sufficiently, and with lights at more frequent intervals than by the electric light. They thought that that additional expenditure, £30 or £40, would serve the town better than by going to the expenditure of an additional £80 or so, hence their recommendation. This was seconded. Councillor Myres moved an amendment that the matter in question be referred back to the committee for reconsideration. He presented a petition from the residents in Church street protesting against the decision of the committee as to the better lighting of the streets. The memorialists understood that the borough surveyor had reported favourably upon the electric lighting. They very much preferred the electric light, and did not see why they should not have the same advantages in this direction as the residents in Fishergate, and they hoped the question would be reconsidered, as there could be no doubt that the electric light was a better illuminant for street purposes than gas. Councillor Humber seconded the amendment. After further discussion the amendment was rejected, and the proceedings of the committee were confirmed.

The Leeds Electric Tramway.—Writing to a Leeds paper on the 26th ult., Mr W. S. Graff Baker says: "I note in your issue of even date a letter on this subject over the signature of Mr. G. M. Roberts, following upon one signed 'Celerity,' in your issue of Monday. As Mr. Roberts says, there can be no doubt that correspondence on this subject from your readers in Leeds would be most valuable in enabling the opinion of the residents of Leeds, with reference to same, to be most correctly arrived at. Having had a long experience in electric traction, and being well

acquainted with all systems in vogue, but yet being in a position where I am not tied to the use of any particular system (as is the case with most electrical companies), I can offer what might be called a composite system of electric traction, which in my opinion would be most suitable for the local conditions obtaining in Leeds. It is on the centre bracket suspension system I would suggest that when the Corporation are relaying the existing double line, the space between the inside rails (when the width of the streets permit) should be increased to 4ft., which is the standard in many towns, notably in Glasgow and Edinburgh. By doing so facilities are afforded for the erection of the centre bracket system as shown, the poles being ornamental in character and placed in the centre of refuges, with low ornamental posts at either end, and capable of safely and comfortably accommodating two persons. These standards and refuges can be placed at least 120ft. apart, and every alternate pole could be fitted to carry electric lights either arc or incandescent for street-lighting purposes, thus securing the ideal position for street lamps, viz., in the centre of the roadway. This, as Mr. Roberts states, is adopted by the St. Pancras Vestry, in the Euston and Tottenham Court roads London. By the adoption of such central system of lighting, the sidewalks are cleared of lampposts, with the effect of helping the appearance of the streets materially, while the standards in the centre become very unobtrusive. The only wires carried overhead would be the trolley wires, all others (including the electric light wires) being laid underground and led up through the centre of the standards to the trolley wires or to the lamps. This system has the great advantage, thanks to the 'refuges,' of assisting most materially in regulating the traffic of the streets, and in maintaining the 'rule of the road.' In streets where double lines do not exist, or where the streets are too narrow to enable the necessary width to be secured between the inner rails to allow 'refuges' and standards as suggested to be erected, I would suggest the trolley wire being carried upon cross-wires attached to ornamental brackets on the fronts of the houses on either side of the street, thus doing away with poles entirely; and in the heart of the city, where the local conditions permit, a conduit system, carrying all wires under ground. This latter system is to be avoided, however, where possible, owing to the fact that no conduit system that would be permitted in England is a commercial success at the present moment, and until the difficulty to be experienced in keeping the conduit free from surface water during heavy rains be overcome, such a conduit system cannot be depended upon for a uniformly regular service, as in the event of the drainage not being perfect, and the conduit filling with water, it would be impossible to operate the cars. In Boar lane, however, I am of opinion that the conduit could be laid to advantage, as the facilities for drainage towards the river are sufficient to enable it to be always kept free from water. The same cars would use either the overhead system or the conduit (where laid) indifferently, and I feel sure that by the exercise of a wise discretion in the combination of the systems suggested, an effect would be obtained that should satisfy most critics. May I point out that the system of double pole cross suspension, as erected in Roundhay-road, was done at the request of the Corporation, a special clause being inserted in my agreement with them demanding the erection of such system. I shall be glad if your readers will care to criticise these suggestions in the columns of your paper."

PROVISIONAL PATENTS, 1893.

OCTOBER 23.

19884. **Improvements in electric indicators or annunciators.** Max Binswanger, 73, St. Stephen's road, Upton Park, London.

19921. **Improvements in time apparatus for automatically switching gas and electric lights.** Herbert Young Dickinson, 36, Gray's inn road, London.

19934. **Improved electricity meter for continuous and alternating currents.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (Compagnie Anonyme Continentale pour la fabrication des compteurs à gaz et autres appareils, France.)

19967. **Improvements in secondary electric batteries.** Wilhelm Petschel, 99, Chausseestr, Berlin. (Complete specification.)

OCTOBER 24.

9989. **Improvements in the mode of and means for operating electric bells.** John Joseph Husselbee, 2, Hunter's-vale, Birmingham.

20011. **Improvements in electric lampholders and switches.** Gustav Binswanger, 73, St. Stephen's road, Upton Park, London.

20023. **Improvements in the method of heating, welding or working metals electrically, and in apparatus therefor.** William Phillips Thompson, 6, Lord street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

20046. **Electric selecting devices.** Samuel S. Bogart and Electric Selector and Signal Company, 17, Basinghall street, London. (Complete specification.)

20047. **Improvements in electrical apparatus for controlling semaphore and other signals.** Michael B. Leonard and Electric Selector and Signal Company, 17, Basinghall-street, London. (Complete specification.)

20069. **Improvements in apparatus for controlling the application or use of electric currents of high tension and great quantity.** Robert Lundell and Edward Hibberd Johnson, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

OCTOBER 25.

20114. **Improvements in galvano plastic processes for the production of decorative objects or articles.** Ernest de Pass, 73, Fleet street, London. (Jules Ranvier, France.)

20116. **Improvements in electrolytic cells.** Ludwig Mond and Robert Ludwig Mond, 6, Lord street, Liverpool.

OCTOBER 26.

20155. **Improvements in or relating to electric bell ringing.** George Grey Turner, 3, St. Nicholas buildings, Newcastle on Tyne.

20191. **Improvements in electric stop motion drawing frames for fibrous materials.** Edward Tweedale, Samuel Tweedale, and Joseph Smalley, Globe Works, Castleton, near Manchester.

20226. **An improved electric clock.** Gaston Hervieu, 9, Warwick-court, Gray's inn, London.

20229. **Improvements in electric arc lamps.** Alfred Julius Boult, 323, High Holborn, London. (La Societe Madhabeau and Fritsch, France.)

20231. **Improvements in electric clocks and electric meters.** Frank Panter and George Hill, 6, Bank street, Manchester.

OCTOBER 27.

20325. **Improvements in the manufacture of electric pushes, pulls, and switches.** William Robert Webb, 4, South-street, Finsbury, London.

OCTOBER 28.

20381. **Improvements in joints for electric light fittings.** Ernest Alexander Claremont, 53, Arcade chambers, St. Mary's gate, Manchester.

20384. **Improvements in electricity meters.** George Hookham, 7, New Bartholomew street, Birmingham.

20402. **Electrical station indicator for use in railway carriages or other public vehicles.** Herbert de Grave, 1, Amberley road, West hill, Sydenham, London.

20408. **An improvement in or applicable to ear-pieces for telephone receivers.** James Watkin Kinnibrugh, 191, Fleet street, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1892.

17826. **Transforming alternating into continuous electric currents.** Hutin and Leblanc.

19543. **Electric telegraphic apparatus.** Stevens.

22035. **Electrical switches, etc.** Binswanger.

22129. **Electric switches.** Wharton.

22858. **Electric arc lamp.** Davenport.

23674. **Distributing electricity.** Harrison.

24071. **Evaporating solutions by application of an electric current.** Schiff.

1893.

2318. **Electric percussive tool.** Williams.

13774. **Maintaining the human body in electrical connection with the earth.** Spratt.

14756. **Dynamo-electric generators and motors.** Brooker. (Ryan.)

15479. **Electric arc lamps.** Howard.

15669. **Electrolytic treatment of liquids.** Browne. (Vogelsang.)

16019. **Metal posts for electric wires, etc.** André.

16074. **Lighting gas by electricity.** Geyer and Stegmeier.

16136. **Battery electrodes.** Boult. (Hensel.)

NOTES.

Glow Lamps.—Lamps are now cheap; the master patent expires to-day. Who'll buy?

Leeds. A difficulty has arisen as to the terms upon which the Corporation is to take over the tramways.

Zurich.—An electric tramway now in course of construction is expected to be completed by the end of the year.

Collision.—A collision the other day between a trap and an electric car in Leeds resulted in the overturning of the trap and injury to one of the occupants.

Brighton.—It appears that the electrical engineer to the Corporation of Brighton still has a vacancy for an articled pupil at the borough electricity works.

High-Speed Engines.—It is announced that the Compagnie de Fives-Lille have devised a new type of high-speed engine intended for the driving of dynamos.

Won in a Canter.—The Shaftesbury Debating Society at Swansea have debated the relative merits, as illuminants, of gas and electricity. Electricity won in a canter.

Post Office.—The Postmaster-General gave on Saturday, at the Mansion House, some interesting information concerning the postal and telegraphic departments.

Personal.—Mr. Francis Teague has been appointed resident manager of the Coatbridge new generating station of the Scottish House-to-House Electricity Company.

The Show.—"Yes," remarked one City man in the train yesterday, "we'll be busy in the City to-day. "Of course," replied another; "but wait till the show is run by electricity."

Inverted Arc Lamp.—The inverted arc lamp which was described in our issue of the 27th ult., was shown in action at the recent meeting of the Institution of Mechanical Engineers.

Munich.—It is submitted, when the central station now being established in Munich is completed, that that city will take the first place among electrically-lighted towns on the Continent.

Fort Beira.—Mr R. G. Webster, M.P., has obtained a concession from the Mozambique Company for the construction of piers and landing-stages, telegraphs and telephones, at Fort Beira.

The Laying of Mains in France.—The Minister of Public Works has just published regulations determining the conditions under which electric light and power cables may be laid under public thoroughfares.

Train-Lighting.—It is pointed out, with reference to our note last week on the extension of the electric lighting of trains on the London, Brighton, and South Coast Railway, that the company are also increasing the number of gas-lighted trains.

Kensington.—The report on the electric lighting of Kensington, prepared by Major-General Webber and Mr. Philip Monson, and referred to in our last issue, considers the question of combining the use of a refuse destructor with steam plant.

Caustic Soda.—The new electro-chemical process, invented by Mr. Castner, for the manufacture of caustic oda and chlorine direct from common salt by electrolysis, regarded by the chairman of the Aluminium Company as romising good results.

Camberwell.—In the course of an interview, Mr.). C. Preston, the leader of the Moderate party in the Jamberwell Vestry, said that until the electric light can be produced at the same cost as gas, there is not much chance of getting it adopted in Camberwell.

Institution of Civil Engineers.—The sittings of the institution will be resumed on Tuesday next, the 14th inst., at 8 p.m., when Mr. Giles, the president, will deliver an inaugural address. He will also present the medals and premiums awarded at the close of the last session.

Pocket Diary and Year-Book.—The "Mechanical World Pocket-book and Year-book" for 1894 has just been issued by Messrs. Emmott and Co., Limited, of New Bridge-street, Manchester, and 85, Strand, W.C. It is an excellent publication for engineers, draughtsmen, mechanics, and others, and is cheap at 6d.

Lord Mayor's Coach.—The carriage-builders who were commissioned by the Lord Mayor to build him a state coach, have just completed a very handsome equipage. The electric light has been introduced in the coach on the same principle adopted for the state coach made for Sir David Evans on his accession to the civic chair.

Junior Engineering Society.—The inaugural meeting of the thirteenth session will take place this (Friday) evening at the Westminster Palace Hotel, S.W. The chair will be occupied by the retiring president, Dr. John Hopkinson, F.R.S., and Mr. John Wolfe Barry, M.Inst.C.E., will deliver his presidential address.

Lubricators.—A copy of their trade price-list of grease and oil lubricators issued by Messrs. O. Berend and Co., of 61, Fore-street, E.C., has been forwarded to us. In addition to containing illustrations and prices of various kinds of oil and grease lubricators, particulars are given of oil-cans, grease-filters, grease and oil syringes, oil-filters, etc. The list will prove of value to the trade.

Fusing of Wires.—An investigation made into the circumstances attending the outbreak of fire in the gunners' storeroom of the second-class battleship "Thunderer" has shown, it appears, that the fire originated with the fusing of the electric wires, which are said to have set fire to the wooden casing and extended to the stores in the compartment. The damage to the ship was comparatively slight.

Large Wimshurst Machine.—A large machine has just been completed for Lord Armstrong by a Fleet-street firm. It has 16 plates, each 34in. in diameter, and gives a spark in air 16½in. long; the glass case in which it is contained, all but the terminals and their supporting tubes, measures 7ft. by 6ft. by 3ft. The thick glass tubular supports of the terminals are made to serve also as condensers.

Proposed Coast Electric Railway.—In a Bill to be promoted next session, the Taff Vale Company may seek permission to construct an electric railway along the foreshore. This would bring Penarth into very much closer connection with the Bute Docks, the existing means of communication along the lower Penarth road being by means of a ferry-boat and waggonette, the latter not being always available.

Lightship Communication.—The United States Lighthouse Board has been successful in forming electrical communication at a distance of more than a mile from shore. The difficulties which have hitherto prevented connecting with the land by electric cable a vessel swinging at anchor at sea are said to have been overcome by attaching the core of the cable to the anchor chain, and making a conductor of the latter.

Society of Arts.—At meetings of the Society of Arts after Christmas, papers will be read by Prof. H. Robinson,

M.Inst.C.E., on "The St. Pancras Electric Light Installation," and by Mr. W. H. Preece, F.R.S., on "Electric Signalling Without Wires." At the first ordinary meeting on Wednesday next, the opening address of the session will be delivered by Sir Richard E. Webster, Q.C., M.P., Chairman of the Council.

The Police and Telephony.—The Hertfordshire constabulary have just brought into requisition telephonic communication between Hitchin, Baldock, and Royston—three of their principal stations. All the police stations in the county are, by order of the County Council, to be brought into direct communication with each other. The wires are fixed to the various telegraph posts, thus curtailing the expense to the local authorities.

Lightning Express Railway Service.—We are informed by Mr. Behr, whose proposed lightning express railway service was referred to in previous issues, that he has arranged with the Thames Ironworks and Shipbuilding Company for experiments to be made on a large scale to perfect the system with special reference to the electrical details. Whilst giving publicity to this item, we must say that we neither think Mr. Behr's system practicable nor desirable.

An Iron Automaton.—Iron soldiers are now suggested, if we are to believe a statement made in a Spanish paper. The inventor claims to have produced an iron automaton, whose inner organs are machinery, and whose diet is cartridges, renewable at will. The rifle which the monster carries can be turned in any direction, and delivers 50,000 shots in 15 minutes! The machinery is set in motion by electricity, but nothing will set the figure itself in motion. Next, please.

Royal Meteorological Society.—The meetings of the society, held at 25, Great George-street, Westminster, will for the future commence at 8 p.m. At the ordinary meeting on Wednesday, the 15th inst., papers on the following subjects will be read: "The Great Drought of 1893 and its Attendant Meteorological Phenomena," by Fredk. J. Brodie, F.R.Met.S., and on "Thunder and Hail Storms over England and the South of Scotland, July 8th, 1893," by William Marriott, F.R.Met.S.

Foreign Patents in Russia.—M. Moskaleff recently submitted to the administrative council of the Russian Imperial Technical Society a scheme for the suppression of all patent rights in Russia for foreign inventions. The proposal gave rise to great controversy among the members of the society, and in a certain section aroused considerable indignation. The society will consequently have to decide by vote whether or not the scheme shall be submitted to the approval of the Council of the Empire.

Railway Rates.—The London Chamber of Commerce is constantly being asked by members for advice in regard to paying their accounts with the railway companies on the basis of 5 per cent. increase. They have always been advised to pay "on account" only (and not including the 5 per cent.) pending the issue of the report of the Select Committee on Railway Rates which sat during last session. This report may be expected this month, and until its tenor is made known the course above referred to is the best that can be recommended by the Chamber.

The Annual Dinner.—Amongst the invited guests who have accepted the invitation of the President and Council of the Institution of Electrical Engineers are the President of the Board of Trade; the Postmaster-General; Sir Thomas Biomefield, Bart.; the presidents of the Institutions of Civil Engineers, Mechanical Engineers, *Iron and Steel Institute*, the Chemical Society, and of the *Physical Society*; the Astronomer Royal; the Hydrographer to the Admiralty; Sir James Crichton Browne; Sir Frederick Bramwell, Bart.; and Sir Robert Rawlinson, K.C.B.

Communication with Lightships.—Two vessels are being prepared, under the direction of the Trinity House, to relieve the lightships at the North Goodwin Sands and the Kentish Knock. Both vessels will be in direct electrical communication with the shore, the cable from the North Sands having its land connection at Dumpton Gap, and that from the Kentish Knock at Kingsgate Bay. The Post Office authorities will lay the cables, and the cost of the work and maintenance charges will be defrayed out of money specially voted for the purpose by Parliament.

The "Medical Battery" Company.—It is now well known that Mr. C. B. Harness has had a writ for libel served upon the *Pall Mall Gazette*, and that the proprietor of the latter has instructed his solicitors to see that no delay takes place in bringing the case into court. Apart from this a receiver has been appointed on behalf of the debenture-holders, and a petition for compulsory winding up the company has been presented, and allowed to stand over for a week. Moreover, Mr. Harness was on Tuesday arrested, in conjunction with others, on four charges of fraud, and has been remanded for a week.

Retrogression in Paris.—It appears that the electric supply companies in Paris have discovered for some time past that the consumption of current has notably decreased, and particularly during the first seven months of this year, as compared with the corresponding period of 1892. It is generally attributed that the falling off is due to the extraordinary development of the Auer intensity gas lighting system which has been substituted in various establishments for incandescent lamps. It is not thought that the success of the Auer system will last for long, as consumers will not fail to ascertain that the economy obtained with this system is more fictitious than real.

The Royal Society.—At the anniversary meeting of this society on the 30th inst., the following will be submitted for election to form the new council for the ensuing year: President, Lord Kelvin; treasurer, Sir John Evans; secretaries, Prof. M. Foster and Lord Rayleigh; foreign secretary, Sir Joseph Lister; other members, Prof. J. B. Balfour, Mr. A. A. Common, Mr. A. R. Forsyth, Mr. Glazebrook, Prof. A. H. Green, Sir John Kirk, Prof. Oliver Lodge, Sir John Lubbock, Mr. W. D. Niven, Dr. Perkin, the Marquis of Salisbury, Prof. Burdon Sanderson, Mr. A. Sedgwick, Prof. T. E. Thorpe, Prof. W. A. Tilden, and Prof. Unwin.

The New Decimal Association.—The third report of the executive committee of this association states that on the whole good progress has been made since the issue of their last report. In May a memorial was forwarded to the President of the Board of Trade pointing out that the weights and measures should be changed before the coinage, and praying him to support the appointment of a select committee to consider the question. No official reply has been received, but it is understood that the President of the Board of Trade is disposed to give his assistance, and that at the first favourable opportunity an announcement will be made.

The Devil's Dyke.—A scheme has been advanced for increasing the attractions of the Devil's Dyke, at Brighton. The project proposes (1) to run a cable-car from a spot near Dyke Station to the ravine from which the place derives its name, and (2) to run an aerial flight about 1,250ft. across the Dyke by means of a car suspended on a cable, and the novelty of which will be that the weight of the car will, to a certain extent, be relieved by a cigar-shaped balloon,

which will be made to rise by the aid of powerful fans worked by electricity. A third portion of the scheme is a steep gradient tramway down to the Devil's Punch Bowl, which will be laid out as tea gardens.

Goldsmiths' Industrial Institute. — The Goldsmiths' Company's Technical and Recreative Institute, at New Cross, has now on its books the names of upwards of 4,000 members. The area over which it extends its influence comprises Greenwich, Deptford, Woolwich, Peckham, Camberwell, and South-East London, and so popular have the various classes become, especially those of art, engineering, chemistry, and plumbing, that this year there have been 11,000 entries, as against 9,000 last year. A technical lecture was, a few days ago, given to the students of the Engineering Society by Mr. J. Macfarlane upon "Nothing; or the Non-existent in its Physical Aspects and as Related to Engineering."

Electrolytic Action on Cables.—The action of electric currents extends to water and gas pipes and to almost all other buried metals, according to a report just issued by the Bell Telephone Company, of Boston. The report states that the overhead single-trolley system of electric railways seems to be the cause of most of the corrosion, and that the heavy currents appear to follow the cable sheaths of telephone cables as conductors. It is said that the lead of the cable sheaths is corroded wherever the current leaves the cable and passes into moist earth or the moist air of the ducts or manholes. The destruction has occurred in some places where the potential was less than half a volt. The injury to water and gas pipes is stated to be as serious as that done to telephone cables.

Influence of Electricity on the Carburation of Iron by Cementation.—A paper on this subject is given by M. J. Garnier in *Compt. Rend.* A bar of steel, containing only 0·1 per cent. of carbon, and a rod of gas carbon, were placed end to end in a refractory tube and well insulated. The tube was then heated at 900deg. to 1,000deg., and a current of 55 amperes and seven volts was passed from the carbon to the steel. After three hours it was found that that part of the iron opposed to the carbon cut glass easily, and a section showed that cementation had taken place to a depth of about 10mm., whilst the carbon was corroded at the surface of contact. Two bars of steel were then packed side by side in wood charcoal with a space of 10mm. between them, and were heated at 900deg. to 1,000deg. for three hours, a current of 55 amperes and 2·5 volts being passed from one to the other. It was found that the bar which served as the anode was practically unaffected, whilst in that which played the part of the cathode cementation had occurred to a considerable depth. It would seem, therefore, that at about 1,000deg. the cementation of iron takes place with very great rapidity under the influence of a comparatively weak electric current.

Electrical Progress in America.—Says a correspondent of one of the daily newspapers: "I went over the Carnegie Works at Homestead a few days ago, and found that the work of handling the bars of white-hot metal as they are drawn from the furnaces, which is done in the great English steelworks by hand, is all done at Homestead by electric machines, which glide back and forth on rails, fetching the long bar out from the furnace, and then drawing it in again by the most ingenious methods. As regards electric lighting, while no city here that I know is so brilliantly illuminated as the City of London by night, yet electric lighting is far more general. Not only in the great cities, miles of roads of the prettiest villas in the world out of Boston being lighted by electricity, but a tiny little co-operative town which I visited a few weeks ago in Southern Illinois, containing less than 150 people, had its two little avenues lighted by incandescent globes. The development of electricity is as much a feature of the marvellous growth of America as is the enormous increase in population. It is a development which is greatly complicating social problems, and which is undoubtedly heading in the direction of municipal collectivism."

E.M.F. in Electrolytic Analysis.—Mr. H. Freudenberg, in the *Zeit. Physikal Chem.*, deals with this subject: It has been shown that different values of the E.M.F. are necessary to electrolytically decompose aqueous solutions of different salts. In some cases the electrolytic separation of two metals from a mixed solution of their salts may be effected by choosing an E.M.F. just sufficient to decompose one salt, but insufficient to decompose the other. The author has made a large number of experiments on this subject, and has succeeded in effecting the separation, in acid solution, of various metals which show normal decomposition values of the E.M.F. Thus, silver may be separated from arsenic and bismuth; mercury from copper, bismuth, and arsenic; and, finally, copper and bismuth from cadmium and arsenic. Solutions with abnormal decomposition values were also investigated, without practical result in the case of the oxalates, phosphates, and ammonium double salts. Cyanides and sulpho-salts, however, often give methods of separation. For example, silver may be separated from antimony, and mercury from copper and cadmium in potassium cyanide solution, and mercury may be separated from antimony and arsenic in ammoniacal solution.

Soldering the Electrodes of Accumulators.—In the *Foreign Abstracts* of the Institution of Civil Engineers, an improved method of soldering the electrodes of storage cells is described by Messrs. K. Strecker and Th. Karrass. In view of the increasing use of storage batteries for telegraphic purposes, the authors found it desirable to devise means of joining up the lead plates more perfectly than by the soldering iron, which frequently effects merely a superficial union; and more easily than with the gas blow-pipe, which is not very portable and requires practice to use it. They have worked out the following method: The strips of lead for making the joints are immersed for some time in strong potash solution, and then well washed with water to clean the surface. Immediately before the operation the ends of the electrodes and the lead strips are carefully scraped bright; they are then held in position in a mould somewhat in the form of a pair of tongs, which completely encloses the proposed junction beneath and at the sides. Melted lead is then poured in from a ladle till the mould is full. After a little practice it is easy to get the right temperature to ensure the superficial melting of the two surfaces by the hot metal, so as to make a perfect joint.

Electric Cooking and Heating Appliances.—From a copy of the first edition of the catalogue dealing with electric cooking and heating apparatus issued by the General Electric Company, Limited, of 69 and 71, Queen Victoria-street, E.C., it appears that a very wide range of these appliances is now available. Of course, with apparatus of this character, one of the most important points which have weight in hotels, restaurants, clubs, mansions, etc., is that of cost. In this connection, the company state that the cost of the current consumed for cooking and heating by means of the appliances described in the catalogue is not great. For instance, a pint of water, with a kettle of 100 volts and three amperes, and with current at heating rates of 3d. or 4d. per unit, can be boiled in 12 minutes at a cost of approximately one farthing. The catalogue gives illustrations and particulars of electric cooking kettles,

coffee-machines; frying, stew, and sauce pans, electric steam cookers, fish-kettles, electric ovens, electric grillers, hot-plates, electric heating irons for domestic and tailors' purposes, electric warming stoves, etc. Among other novelties dealt with are cigar lighters, electric shaving and glue pots, electric curling-iron heaters, portable lamps, electric fan sets, etc. We are informed that the company have been very successful in the production of the electric cooking and heating appliances.

Electrolysis of Steam.—This subject is treated by Mr. J. J. Thomson in the *Proceedings* of the Royal Society. A current of steam was passed through the middle limb of a T-tube, the closed side limbs of which were furnished with delivery tubes, and also with gold or platinum electrodes, between which sparks might be passed through the steam. The delivery tubes conducted the gases into two eudiometers, in which the gaseous mixture formed on passage of the sparks was exploded. When the sparks were from 1·5mm. to 4mm. long it was observed that within the limit of error of the experiment the volumes of the excess of hydrogen in the one tube and of oxygen in the other, which remain after the explosion of the mixed gases, are respectively equal to the volumes of the hydrogen and oxygen liberated in a water voltameter placed in series with the steam-tube; and that the excess of hydrogen appears in the tube which is in connection with the positive electrode, the excess of oxygen in the tube which is in connection with the negative electrode. When the spark length is greater than 4mm., the first of the preceding results ceases to hold, and when the spark length is increased to over 11mm., the excess of hydrogen, instead of appearing at the positive electrode, changes over to the negative, the excess of oxygen at the same time going over from the negative to the positive electrode. When the sparks are very much longer, about 22mm., reversal again takes place, the hydrogen appearing at the positive electrode. The author finds that when the arc discharge passes through hydrogen and oxygen respectively, the hydrogen behaves as if it had a negative charge, and the oxygen as if it had a positive one.

Automatic Starter and Time Recorder.—An automatic starter and time recorder for use in connection with horse racing, pedestrianism, and bicycling has been devised by Mr. Alfred Bartlett, who hails from New Zealand, and who now has one of the machines on view at the office of the Rosehill Racing Club. The mechanism is enclosed in a cylindrical case, on the top of which is fixed a horizontal dial, which is divided into 60 seconds, and each second is subdivided into fifths, while a smaller dial registers the minutes. An outer circle has a number of stops, numbered from 1 to 60, and is brought into use in starting for events in which the time system of handicapping is required. In connection with the "clocking" machine is an electric battery with bell attachments, which is fixed at the starting point, while the time recorder is placed at the winning-post. The mechanism for starting time-handicapped events is brought into operation by pressing down the buttons on the outer rim of the dial, in accordance with the time adjustments fixed for the starters, and, starting from zero, the times at which the other horses handicapped in the race leave the mark are accentuated by a bell, so that no mistake can occur in despatching the field just as the handicapper had arranged. The seconds hand, which registers the time on the large dial, is carried on a cylinder about 3in. in diameter and of a similar depth. The outer surface of the cylinder is vertically divided into 12 parts, corresponding with which, on the inner surface of the cavity in which it revolves, are a dozen inked points. The circumference of the cylinder is divided into seconds and fifths, and the aforementioned inked points are electrically connected with the tapes at the winning end of the running tracks. The signal for starting is given by a loud-sounding electric bell at the starting-post, and simultaneously the recording machine at the other end is brought into operation. The tapes at the winning end of the tracks are electrically connected with the inked points, and the instant that the connection is broken the inked point registers on the corresponding section of the revolving cylinder the time occupied in covering the ground, as well as the relative positions of each competitor as he breasts the tape.

City Lighting and Telephony.—The members of the City Commissioners of Sewers were much concerned on Tuesday on the subject of electric lighting. Alarmed by a statement that there were serious defects in the "electrical arrangements" of a City firm, the Commissioners unanimously decided to refer to the Streets Committee the question of appointing inspectors under the Electric Lighting Acts. It was also resolved to refer to the same committee the subject of lighting Crutched-friars by electricity. Mr. C. T. Harris, who moved this resolution, mentioned that the cost of lighting the eastern district was nearly 20 per cent. in advance of that for the main thoroughfares of the City. In the eastern district there were 233 arc lights, which at £26 per annum, cost £6,058; adding to that the cost of maintaining disused gas lamps, about £450, the total would be £6,500. The previous cost of lighting by gas the whole (three districts) of the City with 1,730 lamps was £5,550. To light the district by electricity thus cost £1,000 in excess of the expenditure required to light the whole of the City by gas. At the same meeting the engineer submitted a report on the failures during the past six months in connection with the electric light. The total number of arc lamps in use was, he reported, 475. The number of gas lamps disused, but maintained ready for lighting, was 1,219. The total number of failures of the electric light during the period in question was 301. The most serious failure was on May 7, when 42 lamps were not lighted until 9 o'clock. The explanation given by the company was that the switch was defective. On June 17, 65 lamps went out for a considerable period, but the gas was not lighted. The explanation given by the company was that there was negligence on the part of the stoker at Wool-quay. On July 27, 96 lamps went out, and the reason given was the breaking of a belt. The 475 arc lamps at a cost of £26 per annum each gave a sum of £12,350. The length of streets lighted was 13 miles. The fines for these defects would be deducted from the next account of the company. The information regarding these failures was received from the police force, and the returns were sent to the company's office, and filed in his office. This report is now being printed and circulated. With regard to the telephone tubes of the City of London Electric Light Company, the Commissioners were gratified—for the present, of course—to learn from the company that except for purposes of their own the tubes were not being used for telephonic purposes. As a wind up on matters electrical, the Commissioners instructed the Streets Committee to work in accord with the Association of Municipal Corporations on the subject of the agreement to be signed between the Government and the National Telephone Company.

Electricity in Coal Mining.—A paper on "Collieries and Colliery Engineering," referred to in our last issue, was read on Monday evening before the Society of Engineers by Mr. R. Nelson Boyd. In the course of the paper the author said that the gradual development of the coal

trade had brought with it the necessity for improved means of transport, both above and below ground. Every kind of conveyance has been from time to time applied in coal-mining, from the backs of women, in Scotland, up to the electric locomotive as now introduced in some mines in Germany. The question of undercutting the coal by machinery had been very much considered. One of the most recent was the electric coal-cutting machine brought out in 1887 by Messrs. Bower, Blackburn, and Mori. This consists of a frame travelling on wheels carrying a specially-designed electric motor driving a shaft which carries the cutter attached by bolts to a coupling. This cutter consists of a bar carrying a series of star-shaped cutters specially formed. The whole motor and the shaft carrying the cutter-bar can be rotated in a horizontal plane for the purpose of bringing the cutter in and out of the coal. The cutter is revolved by an electric motor at the rate of about 600 revolutions per minute, and the motor develops a power of six to nine actual horse-power, according to the hardness of the seam. When cutting is commenced the motor is started, and the turntable rotated by a worm wheel till the cutter has swept through a right angle, and is 3ft. 6in. deep in the coal. It is then drawn along the face by a winch under or overcutting the coal to that depth. The actual work effected by this cutter has been 45 yards in an hour, including all stoppages. The power is transmitted from dynamos on the surface by means of two cables. The author said that the electric coal-cutter had not had time to become established as a success, and in general use certainly no coal-cutting machine had as yet proved universally applicable, although there were some machines in daily use in different districts. It would seem that the different peculiarities of various coal-beds as to thickness, hardness, inclinations, and so on, almost required a different kind of machine for each bed. With regard to the transmission of power by steam, ropes, compressed air, electricity, petroleum or gas engines, and by other means, the results obtained by these diverse systems had not yet been sufficiently definite to enable a decided preference to be given to any of them. But it seemed as if for this purpose electricity would gain the day. At any rate, so far, the results had been favourable. Steam and compressed air had been in use for some time, but they were expensive on account of the loss in transit. Ropes gave very good results, but absorbed much power through friction if they had to be carried round and over many bends. Petroleum and gas engines remained to be tried, but an obvious objection to their introduction in a fiery pit was their danger. Electricity had been objected to on the same grounds, but with careful arrangements the transmission was practically safe. As an example of the progress that electricity has already made, as applied to the transmission of power underground, he gave a description of the electric plant in use at one of the Earl of Durham's collieries, and which is, perhaps, the largest applied to mining. The author concluded that electricity has to overcome a certain amount of prejudice and a good deal of apprehension as to danger on the part of colliery engineers, but it appeared to be making headway as a transmitter of power. For illuminating purposes underground, it had so far not proved a great success, and a practical miner's electrical lamp yet remained to be invented.

Checking Electric Supply.—In a recent issue of *L'Industrie Electrique* a description is given of the Martin check apparatus for electric supply. The following *résumé* of this article is given in the *Foreign Abstracts* of the Institution of Civil Engineers: "It is very usual in France for an electric lighting company to furnish current by contract to consumers, and in such cases a consumer may have any number of lamps installed so long as he never has more than a certain fixed number lighted at once. It is therefore necessary to use some apparatus for the purpose of preventing fraud and making it impossible to use more than the stipulated number of lamps at one time. As a rule, this object is accomplished by using switches with two or more different contacts, so that when the current is shut off from one circuit it is admitted to others. This method, however, complicates the internal wiring, and the grouping of the lamps easily permits of fraud. On the other hand, the reliability of cut-outs is very doubtful. The Martin apparatus is designed to prevent the use of more than the stipulated number of lamps, while permitting absolute freedom in the grouping or wiring of such lamps. Such an apparatus is also of use in a private installation, to prevent overloading of the generating plant. The apparatus is placed in one of the main leads, and consists of two mercury-cups provided with a metal contact-maker attached to the end of a lever, and provided with a spring to cause a quick break in the mercury cups. The lever is commanded by one or other of six pins standing at right angles to the flat face of a wheel, which is stationary when the stipulated current is not exceeded, and holds the contact in the mercury-cups. Clockwork is so arranged as to always tend to rotate the pin-wheel, and if this motion were not controlled, the circuit would be made and broken at short intervals by the contact-piece in the mercury-cups. One of the train of wheels is, however, provided with a single pin, which is held by a projection on a spring lever during the whole time that the current in the circuit does not exceed the quantity stipulated. The spring lever carries at its free end the armature of an electromagnet, which is placed in the main circuit, and the strength of the spring upon the lever is so adjusted that, so soon as the maximum stipulated current is exceeded, the armature is attracted and the train of wheels set free. Contact is then made and broken at short intervals of time, and the customer is obliged to take one or more lamps off the circuit, thus bringing the current down to the normal when the train of wheels is stopped and the permanent contact is again made. In actual practice a clock movement of the Japy type is employed, but only the five wheels of the striking mechanism are preserved, with the detent spindle and its lever, and the spindle of the hammer. The hammer shaft is retained, but the head is replaced by a piece of hard rubber, carrying a copper fork dipping into the two mercury-cups. The author gives some further details of the method of manufacturing this particular type of clock. He states that the act of switching in a 5-c.p lamp on a circuit of 110 volts is sufficient to actuate the apparatus—supposing, of course, that such a lamp be in excess of the stipulated number of lamps which are already lighted. The loss of pressure upon the circuit is said never to exceed 0·2 volt. The whole is covered with a glazed lid, and can be sealed up. A counterpoise is so arranged that it is impossible for a consumer to keep too many lamps lighted until the clock has run down, in which case the circuit would become permanently closed; the counterweight causes the circuit to remain permanently open until the number of lamps in use is reduced to the stipulated maximum. This instrument has, it is stated, given satisfaction in one of the eastern towns, and a servant of the company calls once a month upon each customer for the purpose of winding up the apparatus. Such a clock-movement would run for 15 days, and give 2,700 interruptions, and it is found that the spring is very seldom run down in a month."

REGINALD BELFIELD.

Electrical engineers are cosmopolitan, and, as is well known, many enterprising men have gained their experience from both sides of the Atlantic. The subject of this sketch is one of these. Born in Barbados in 1863, he received his education first at Harrison College in the island, and afterwards at Cheltenham College in England. It was during his life at Cheltenham that he first became interested in the study of electricity, and after leaving Cheltenham, Mr. Belfield entered the late School of Electrical Engineering, where he became a pupil of Mr. Desmond FitzGerald, whom he afterwards assisted in experimental work in secondary batteries and incandescent lamps. Subsequently Mr. Belfield joined the firm of Ferranti, Thompson, and Ince, afterwards going to the National Company for the Distribution of Electricity (better known as Gaulard and Gibbs), and for this company went out to America to introduce the secondary generator system in the States. In 1885 Mr. Belfield joined the Westinghouse Electric Company, then in process of formation, and the year following went with Mr. Stanley, the electrician of the company, to his laboratory in Great Barrington, Massachusetts, and assisted him in his experiments with the transformer and dynamo which were afterwards manufactured in such large numbers by the Westinghouse Company at Pittsburgh. After about a year at the laboratory Mr. Belfield returned to the works laboratory at Pittsburgh, and assisted in the development of the alternate-current system adopted by the company. In 1888 he came over to England in the interests of the Westinghouse Company, and on the formation of the Westinghouse Company of London was made chief electrician, which position has been held to the present day. Mr. Belfield is a member of the Institution, an associate member of the Institution of Civil Engineers, and a member of the Society of Arts. This rapid review of the experience of a young man will show that energy, knowledge, and adaptability to circumstances still play an important part in bringing about success.

ELECTRIC SUPPLY COMPANIES. I.

(Continued from page 415.)

WESTMINSTER ELECTRIC SUPPLY.—GENERATION AND DISTRIBUTION.

The arrangements of the generating plant in the various central stations on the Westminster system having been described, there remain certain considerations of general policy as regards distribution, means of securing constancy of supply, testing the circuits, the important relation of cost of generation to sale, as well as the manner of regarding the general accounts, which it will be interesting to mention.

The distribution is carried out on the usual three-wire system—a network of bare copper mains with middle neutral wire, run in concrete conduits, and fed by feeders from the dynamos at 225 volts. The two sides of the three-wire system are kept in balance for the large variations by occasional readjustments of house connections to one side or the other of the mains; and daily at the station by the use of the balancing machines, whose current is continually adjusted to supply the slight excess on either side of the mains.

The accumulators are kept constantly connected on the mains, so that no break in the supply is experienced. In times of light load during the early morning the accumulators take the whole service, the regulation being then, of course, accomplished by switching in a greater or less number of cells on either side of the network. The use of accumulators is testified to by Prof. Kennedy as having been "a great blessing." The only cost for maintenance is that of a few new plates, and the first cost, though greater than that for machinery of a corresponding output, is not found unreasonably high, while the convenience is enormous. By their use the plant at all stations is entirely shut down every night for some hours—as much as eight or ten hours (from 12.30 a.m. to 9 a.m. or 10 a.m.) in summer, and in winter from 2 a.m. to 7 a.m. The whole network of mains is connected together, and the stations at Millbank-street and Eccleston-place take the entire day load every alternate week. The networks are separated every two months for testing.

At each station the mains are tested every morning for earth; they are put to earth through a low-resistance ammeter by means of a flexible cable to a good earth made in one corner of the station, and the leakage noted. They are tested (1) for difference of voltage of each wire and the earth, and (2) for earth leakage. There is, of course, always some leakage to earth, but it is very slight indeed when it is remembered that there are 120,000 lamps connected in over 1,200 houses. The only occasion of a bad earth is when accidentally some company or vestry workman during the street repairs drives a pick into one of the armoured cables, which occasionally happens. A leakage of 100 to 150 amperes is thus sometimes set up when the mains are put to earth. When this occurs tests are taken at once to see which feeder is most affected: this will be the one nearest to the place of accident; the network at this district is isolated and tested with a testing set, the leak is found and the cable repaired.

With regard to the important question of earthing the wires, it is interesting to note that Prof. Kennedy finds the tendency in a three-wire system is for the negative main to get to earth potential. On first installation, when there were few connections, it was irregular, and fluctuated on either side. The middle wire for some time tended to get to earth, and Prof. Kennedy was long urged by the authorities to put the middle wire to earth, but refused, and, as it seems, with reason. The current at last adjusted itself definitely, and the tendency uniformly now is for the negative main to go to earth potential. This is so even if the mains are changed over. Mr. Monkhouse, superintendent of mains, has opened, for instance, a culvert where the negative is practically at earth potential, and the positive is 200 volts above earth, and he has then changed over. In 24 hours there will be no earth at all, and in three or four weeks the earth will go over to the other side—that is, to the then negative main. This seems to be an interesting feature worthy of note by electrical engineers, but of which the explanation is not easy to suggest.

The mains, in practice, are not found to give the least trouble with corrosion. There is no eating away of the copper perceptible after several years of use. The bare copper strip simply gets blackened and discoloured, but the surface remains smooth, and there is nothing that can be felt with the fingers to show any signs of incipient corrosion. There is absolutely no complaint on this score.

NATURE OF INSTALLATIONS.—The varying consumption for different classes of installation is a point of much interest to electrical engineers. By the kindness of Prof. Kennedy and the directors of the Westminster Corporation, we are able to give definite information in tabular and graphical form as to the varied rate of consumption during the different periods of the year in various installations supplied in the Westminster district.

It is, of course, somewhat difficult accurately to tabulate all the different installations in exact classes; but the classification adopted is sufficiently detailed to give useful information and guidance. The kind of installation in the Westminster district using the most current is that of public lights in the corridors of mansions. Clubs come next in the extent of consumption per lamp, and then hotels; after these shops, offices, flats, houses, and churches, in the order named. The following is the amount of

current consumed during the year 1892, expressed in units per 8-c.p. lamp per annum:

Nature of installation	Total units per 8 c.p. lamp per annum.
Public lights	51·7
Clubs	45·8
Hotels	38·4
Shops	17·2
Offices	16·1
Residential flats	13·6
Private houses	9·7
Churches	8·8

Rather a striking point in this table is the comparative smallness of consumption per lamp in private houses; it is only two-thirds that in offices, and but little over the last class—churches—where naturally one would expect the consumption to be small. House-lighting apparently is not so remunerative as most other installations, but the apparent anomaly is doubtless due to the fact that in private houses many more lamps are installed than are intended to be kept in constant use, which causes the average consumption per lamp to appear very low.

Cost of Generation.—We now come to the last and most important item, of the relation of cost of generation to sale of current. Taking the question generally, there are four chief heads under which the expenses of running an electric light company will fall:

1. Cost of generation—comprising salaries of engineers and staff, repairs, fuel, and general charges pertaining to generation and maintenance.
2. Central expenses—directors' fees, office salaries—not engineers', law, etc.—charges pertaining to revenue.
3. Rent, rates, and taxes.
4. Depreciation, and other charges in the discretion of the company.

These items added together and subtracted from the total revenue will give the profit.

It would be well if all electric light companies and municipal bodies working electric installations would agree on one model form and method of charging their accounts. There are several items of a fluctuating nature, which often are obscurely stated in the published returns.

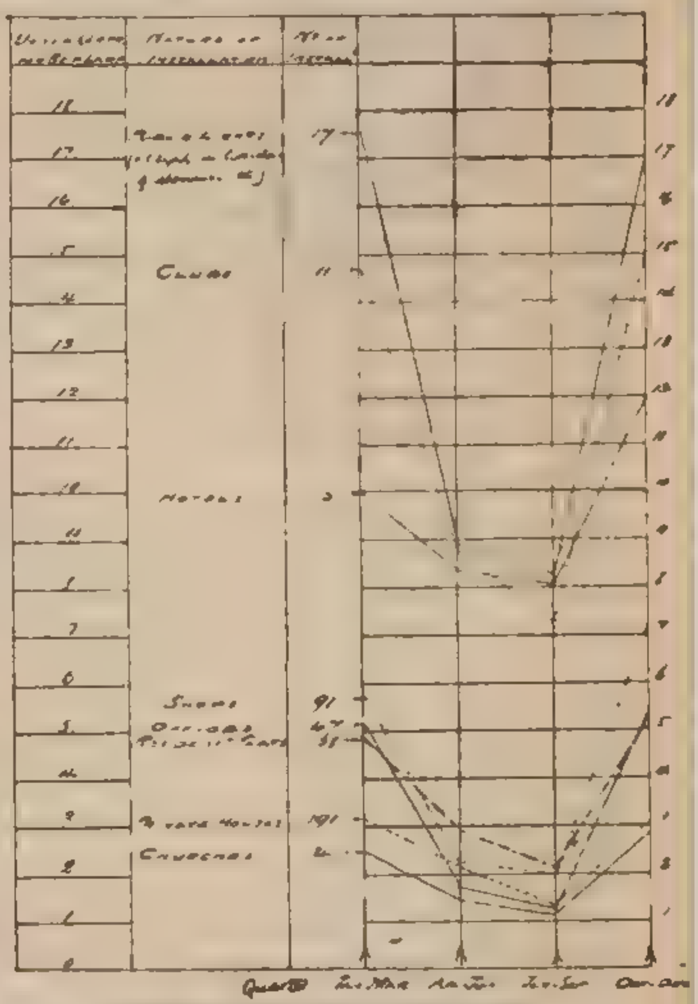
In Item 1, "Cost of Generation," for instance, should be reckoned all engineers' salaries (chief and resident), as well as the wages of the working staff. The engineers are clearly only required for the proper generation and supply of current apart from commercial considerations, and should be so charged. Several companies, however, wrongly include chief engineer's salary in the general expenses.

The cost of generation, which in the Westminster Corporation amounts to 1·08d. per unit, may be considered in two parts: (a) that part which can be influenced by the engineers-in-charge and the staff—such as coal, oil, water, waste, and repairs—and (b) the part which cannot be so influenced—viz., wages and salaries. On the part (a) of the cost of generation, a bonus is allowed by the Westminster Corporation to the staff on all profit or saving after a certain amount. The chief engineer estimates at the beginning of the year the cost of generation per 1,000 units, and 10 per cent. of any saving over this is distributed to the staff in proportion to their salaries. This bonus sometimes equals a full extra week's wages at the end of the year—a very acceptable present, and one which gives the men an interest in the schemes of economy promoted by the engineer.

With regard to Item 2, this includes all general salaries, expenses, and fixed charges not included under rent, rates, and taxes, with the special exception of chief engineer's salary, which, as above mentioned, is often lumped among other salaries, to the apparent lightening of the cost of generation; but as his great function is to lower the cost of generation his fees really constitute a charge on that item, and not on general expenses.

Rent, rates, and taxes, again, are sometimes not fairly charged. If the site is freehold the rent may be left out of the accounts, but this is clearly not good accountancy. The company in that case would be their own landlord, and the item rent should appear at its correct value.

Over the last item, "Depreciation," many discussions have been waged. There are two difficulties to be considered: the plant must be kept up to a state of full efficiency and therefore it may be considered that proper repairs and maintenance keep the machinery to its original point—as, for instance, railway rolling-stock is kept. But on the other hand, machinery not only depreciates in working: it goes



Distribution of Output between Four Quarters, 1892.

out of fashion. Engineers and inventors do not stand still, and the machinery may have to be taken out and replaced. Even if in as good condition as at first, its value depreciates, and a fund must be kept to guard against these contingencies. This question of depreciation is of special importance in comparing the installations of companies and public corporations. The town councils, having borrowed money for 30 years at 3 per cent., write off depreciation so fast that at the end of the time all the plant has been paid off and stands in the capital account at £ nil: this the companies, having dividends to consider, cannot afford to do.

We will conclude this account of the Westminster Corporation by giving the leading particulars of the working for the first half of this year. This electrical balance sheet is for a period of 25 weeks, which happens to correspond with their meter readings:

Electrical Balance-sheet, January to June, 1893 (25 Weeks).

	Total.	Percentage.
Units paid for by consumers	808,214	84·5
„ used for station lighting	18,600	1·9
„ used for meter testing	951	0·1
„ lost in batteries	10,485	1·1
„ expended in distribution	97,032	10·1
„ unaccounted for	21,544	2·3
Total units generated	956,826	100·0

		Per unit.
Income by sale of current	£20,979	6·23d.
Meter rents	857	·26d.
Total	£21,836	6·49d.

The maximum charge to consumers for the first quarter was 7d. per unit, and for the second quarter 6d. per unit. It will be seen that the average income for the half-year was 6·23d. per unit.

The following are the station costs for the half-year per unit paid for by consumers.

Salaries	0·212d.
Wages	0·625d.
Fuel	0·768d.
Stores	0·069d.
Oil	0·049d.
Water	0·081d.
Renewals and maintenance	0·226d.
Total	2·028d.

The weight of coal used during the same period works out to 7·38lb. per unit sold, as against 9·88lb. in the corresponding period of last year.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.*

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

XIV.

(Continued from page 391.)

RESISTANCE, *continued.*

Siemens's Resistance-measurer.—A very ingenious modification of the differential galvanometer for the purpose of measuring resistances of varying magnitudes was devised by the late Sir William Siemens. Its main features are that the readings are made by means of a vernier on an equally divided lineal or circular scale, on which each division signifies a unit of resistance; that only a single unalterable known resistance is required, with the occasional employment of another for purposes of comparison and calibration; and that, as in the ordinary differential galvanometer, the readings are totally independent of the deflection-function of the instrument, the galvanometer needle being always brought back to its zero mark before a reading is taken.

The essential difference between this instrument and the ordinary differential galvanometer for measuring resistances is as follows: In the latter case the coils remain stationary, and the effect of the two currents on the needle are neutralised by altering the value of R_1, the known variable resistance, until the currents themselves are equal. The value of R, the resistance being measured, is then ascertained from the reading of R_1, which must be exactly equal to it.

In the Siemens instrument the value of R_1, and therefore of each of the two currents, remains constant during a measurement, and the effect of the two currents on the needle are neutralised by altering the position of the coils relatively to the needle until the effect of the stronger current, by reason of its greater distance from the needle, is just balanced by that of the weaker. The value of R in this case is ascertained by observing the position of the coils relatively to the needle.

Fig. 36 illustrates the principles involved in the construction and use of this instrument. The swinging needle is suspended just as in the ordinary differential galvanometer with its centre in the centre-line of the two coils, and its indicating pointer clear of them. The two exactly similar coils C and C_1, instead of being fixed to the baseboard of the instrument, are rigidly mounted on a sliding-bar B E which has sufficient movement in the direction of its length to permit of either coil being brought up close to the swinging needle. The sliding bar B E, which is supported on guide rollers, is provided with a pointed agate tip E which is kept continually pressing against the face of the inclined curve M N by means of a spring at the other end of the bar. Thus, if a downward motion is given to M N the sliding-bar and coils move to the left, and so bring the coil C_1 up towards the needle. If M N is moved upwards then the spring causes the bar and coils to travel to the right, the agate point following the curve, so that the other coil C moves towards the needle.

The inclined curve M N slides against a scale graduated in equal divisions, and is provided with a vernier to read to tenths of a scale division. The transverse motion of M N is obtained by means of a rack and pinion as shown in the illustration, Fig. 36.

The whole apparatus is mounted on a horizontal metal table supported by three levelling screws. The two coils, the suspended magnet, and the scale for observing the zero *of the pointer,* are all contained within a glass case, outside *of which are a contact maker, K, for* making and breaking the circuit, and six terminals—two for the battery connections, and four for coupling up the known and unknown resistances, R_1 and R. The connections are arranged so that the battery current is divided between two circuits as shown. One circuit contains the coil C_1 and the known resistance R_1, and the other contains the coil C and the unknown resistance R. In each of these two circuits is placed a current interrupter in the form of a plug, to allow of either or both circuits being readily broken when desired.

The calibration of the instrument consists mainly in determining the correct form of the curved surface M N. Theoretically, this could be obtained by calculation, using Weber's formula for the moment exerted by a current of known strength in a circular conductor, upon a freely suspended magnetic needle, but owing to the difficulties of constructing the coils accurately and of obtaining all the necessary data with sufficient exactitude, it is preferable to determine the form of the curve for each separate instrument empirically. To do this a carefully calibrated resistance box or rheostat is connected between the terminals provided for the unknown resistance, and a succession of positions of the agate point E are obtained, each corresponding to no deflection of the galvanometer needle for a different value of R. These positions are next marked off on the sliding-piece, to which successive transverse motions are given so as to make the scale readings correspond with the successive values of R, and the required curve M N is then drawn through the succession of points thus obtained. In practice Sir William Siemens used a similar method of calibration to this.

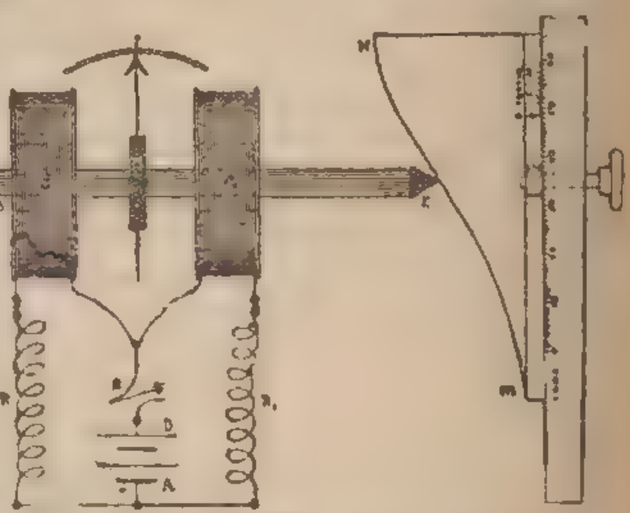


FIG. 36.—Diagram of Siemens's Resistance-measurer with Connections.

In addition to the single fixed known resistance R_1, which always accompanies this instrument, a second known resistance is generally supplied, so that check readings may be taken from time to time for the purpose of testing the accuracy of the instrument. This second known resistance is also extremely useful for readjusting the zero point after the instrument has been altered in any way, or if a new silk fibre suspension for the needle has been put in.

In practice the manipulation of the instrument is extremely simple. R the resistance to be measured is connected up between the terminals as shown, and the sliding piece M N is moved transversely by means of the rack and pinion until the closing of the contact-maker K causes no deflection of the galvanometer needle. The resistance of R in ohms is then read off directly from the fixed scale with the aid of the vernier on M N.

The device for adjusting the position of the coils can also be made so that the fixed scale and the sliding piece M N, instead of being flat, as in the instrument illustrated in Fig. 36, form part of the surface of a cylinder. A turning instead of a sliding motion must of course be given to M N in this case.

This instrument excels the ordinary forms of Wheatstone's bridge both in accuracy and range, besides being cheaper and much more portable. Both the range and the sensibility of the instrument can be varied within very wide limits by altering the dimensions of the coils and the form of the curved surface M N. It has been found of great

utility for the reading of resistance thermometers—that is, thermometers which depend for their readings on the variation of the electrical resistance of wires exposed to the temperatures being measured, and it has also been found of service, before the days of testing-sets, for the measurement of the wire resistance of overland lines.

(To be continued.)

MOTOR GEARING FOR ELECTRIC TRAMCARS.

(Continued from page 417.)

At the present time—and until, in fact, we are able to design electric motors for tramway work to run at extremely slow speeds (say, 80 to 100 revolutions per minute) with high efficiency (88 per cent. at least) and for powers as small as 10 h.p. to 20 h.p.—it may be assumed that a speed-reducing gear becomes essential in order to connect the motor and car axles.

But if the slow-speed motor should ever obtain this position, its features are in other respects such as will bring it at once to the front. Not only would it avoid the use of toothed wheels in any form between the motor and car axles, with all their attendant noise and loss of energy, but by mounting a separate motor upon each car axle—with a disc spring connection such as that devised by the Short Electric Company—all the car wheels may be used as drivers.

This step, of course, involves the employment of at least two, if not four, motors to each car; but any disadvantage thus occasioned—in first cost or expense of operation—may be balanced by the expense and losses of energy that follow from the necessary use of connecting or side rods, if, as in the Eickemeyer system, a single motor be placed centrally between the two car or bogie axles, driving the latter by a coupling-rod on each side. The chief advantage of the latter method, as compared with the use of motors whose weight rests directly upon the axles, is that it avoids the heavy "pounding" on the rails when passing over joints, the weight of the motor being carried by springs. Any comparison between the Short and Eickemeyer systems of arranging level geared motors must be based upon the respective efficiencies of one large motor or two small ones of total equal output, and also of side coupling-rods as opposed to a flexible spring coupling.

Returning, however, to the speed reducing gears as being those essentially of service under ruling conditions, these resolve themselves practically into two main types—first, those employing frictional resistance in the connecting gears; and secondly, those dependent upon the intermeshing of teeth in various forms. Of course, if we are to accept the statement that friction between two surfaces, as, for instance, a driving belt and pulley, is nothing more nor less than the intermeshing of extremely small protuberances on the respective surfaces, these two classes may as well be thrown into one; but for explanatory purposes, we shall with advantage retain the division.

In the first class of gears, those which have been experimented upon for electric tramway work are unable to lay claim to any great success. Apart from friction pulleys—such, for instance, as the proposed friction arrangement of two discs at right angles to give in addition a variable speed by moving one of them to or from the centre of the other, or the use of compressed paper pulleys to drive iron pulleys on the car axles (in both cases the pressure required to prevent slip being a fruitful cause of sprung axles)—the plan generally adopted has been to use ordinary link leather belting with double-flanged iron pulleys.

The idea of using a belt for power purposes where only a very short drive can be obtained, and where the conditions of working are likely to cover the belt with dust and dirt, would hardly appeal strongly to the mechanical engineer. In one instance, however, as stated in Table A (published last week), this type of gear has been successfully employed at Brighton, although it must be confessed that specially favourable conditions are prevalent, and also that worm gear has now been adopted for this line, which, moreover, does not involve the serious consideration due to a standard street tramway. Leather belting of this kind has for that matter, however, been used for some time in railway work, as on the London and Brighton line, for the reverse action of driving dynamos in the guards' vans for lighting the trains electrically, the driving pulley being mounted on the van axle. So far as railway and tramway conditions are comparable, it is therefore at least possible to make out an excuse for the existence of such a method of gearing, but not much more than this can be said.

Ropes of cotton worked in grooved pulleys, either separately or endless, with a jockey pulley for tightening, have also been suggested, but though serviceable enough in a cotton mill for transmitting 1,000 h.p. or more, and perhaps—though that is doubtful—in electric lighting stations where the unit of power is about one-fifth of this amount, such a method is totally out of place underneath a tramcar, and had better be put aside at once as unsuitable.

In one instance small cords of steel wire wound spirally and running on grooved pulleys (just as with cotton ropes), have actually been tried; they worked quite noiselessly, but were unable to transmit heavy sudden stresses owing to the slip between the two surfaces.

Turning now to the second class of gears, we come to the question of toothed wheels in some form or another, and here there are many types not only worth mentioning, but of value for the purposes of tramway work.

Probably the first kind of such gear to be used for this work was the straight-toothed spur wheel, and engineers have apparently ranged from this through all manner of devices only to return once more to its use. Since, however, we have seen that systems of double-reduction gear at first came generally into use, the excessive noise and waste by friction, etc., of four toothed wheels at least to every car—sometimes twice as many—led engineers to experiment with other types of gear for one or other of the two sets of wheels, and hence the chain and sprocket wheel came into service.

Although this method of gearing is doubtless much quieter than spur wheels, so long as the chain is comparatively new, unworn, and unstretched, yet as wear sets in chain gear becomes even more noisy and objectionable than toothed wheels, whilst it is much less easy to protect from dust and mud. The experience hitherto gained in this direction has not been such as would greatly recommend the extensive use of chain gear, even for the slow running of a second motion shaft in a double-reduction system. The average speed of the chain when thus employed would be probably about 500ft. per minute, which is well within the working limits of the hardened steel parts, for in some cases chain gear such as that made by Mr. Hans Renold, of Manchester (who designed and furnished chain gear for the Bessbrook and other tramways), has run without difficulty at a speed of 1,000ft. and even 1,500ft. per minute.

No trouble is experienced with this type of gear from want of strength, but the great wear and tear has proved the chief obstacle to its use. Mr. Renold now insists on as much consideration being given to the wheels as to the chain, and he makes the driven wheel alone equal in pitch to the chain, that of the driver being much greater. That is, the spaces between the teeth on the driver are considerably wider than is just sufficient to enable the chain rollers to embrace and leave the teeth.

In spite of these recent improvements in chain gear, it seems hardly likely, however, that it will come into extensive use for electric tramway work, when its failings are compared with the greater simplicity and ease of operation of spur gear. Several forms of the latter have been used on electric tramcars, as may be seen from the table given in the last article. The favourite kind, however, appears to be the straight-toothed wheel, the pinion or motor axle wheel of bronze, and the large car wheel of cast iron. These materials are, of course, capable of variation, and they are often in consequence varied largely according to the fancy of engineers. Thus, we may find any of the following combinations at work:

Pinion.	Large Wheel.
Best hammered steel.	Cast steel.
Phosphor bronze.	Steel.
Raw hide	Cast iron.
Raw hide and steel—built up in alternate discs.	Steel.

In the majority of cases the pinion wheel teeth—if not those of the larger gear wheel—appear to be machine-cut; and the easier running thus to be obtained is almost worth the expense of cutting, or, at least, machining the teeth of cast wheels also. In order to avoid the noise and shock at starting or going backwards, when the teeth of spur gears engage with one another, the double helical type has been introduced in one or two instances, with excellent results; and two of the most recently-equipped lines—Birmingham and South Staffordshire—it will be seen are provided with this form of gear on the cars. The first cost is, of course, greater than that of ordinary straight-toothed wheels, but the running is much "sweeter" (as engineers say) and easier: this is due not only to the V-shaped form of tooth when seen edgeways (by means of which there is obtained, for equal widths of rim, a contact or wearing surface much greater than with the straight-toothed gear), but also to the care necessary in making and cutting the wheels so as to ensure accuracy of fit.

An ingenious arrangement of straight teeth has been proposed by American engineers for the purpose of obtaining equally good results in running: this idea comprises practically the fastening together side by side of two ordinary straight-toothed gear wheels, but with the teeth of one slightly in advance of those of the other. This "staggered" arrangement, as it is called, resembles exactly the effect given on the Abt system of rack railways, where a toothed pinion with one, two, or even three sets of teeth, set one in advance of the other, gear into a rack placed on the ground and composed similarly of one, two, or three separate toothed bars, the teeth of each bar being placed respectively opposite the spaces of the next, and so on.

This type, however, whilst undoubtedly ingenious, has not come into use at all. It would be cheaper to make than the double helical gear, and has the advantage of affording a comparatively large width for the gear wheels; but it also implies bolts and nuts, or other such unmechanical and undesirable fastenings for securing the two half wheels, unless they be cast in one, in which case the cost of cutting the teeth would be about as much as with the double helical gear, whilst the working results would prove less satisfactory.

(*To be continued.*)

WHAT IS ELECTRICITY?—V.

BY SYDNEY F. WALKER.

THE LINK BETWEEN ELECTRICITY AND MAGNETISM.

The writer had intended to defer the continuation of his articles on this subject until the book on which he is now engaged had been safely piloted through the press, but having the good fortune to be present at a lecture by Prof. Ewing, in which he explained his theory of molecular magnetism, and illustrated its working by means of the beautiful models that he has arranged for the purpose, the after study of the subject led the writer to attempt the solution of what he has always regarded as one of the most difficult problems in the task he has set before him.

As readers of the *Electrical Engineer* will know, it is sometimes comparatively easy to formulate a theory, but very difficult to follow that theory wherever it leads, and still more difficult to account for every known phenomena by means of it. To the earnest student of electrical phenomena, the connection between electricity and magnetism must always be exceedingly puzzling.

The results obtained by the development of magnetism are in nearly every case totally unlike those obtained from the generation of electricity, except when bodies possessing the one form of energy are used to generate the other form—in other bodies—and yet each may be used to generate the other, and may be transformed into the other at will. What, then, is the connection between the two forces? Prof. Ewing very properly lays the greatest stress on the fact which he has discovered, that in the phenomena known as hysteresis energy is actually consumed—so far as energy can be consumed—in the act of turning the molecules to and fro upon their several axes. That is to say, energy *imparted to the molecules* by the electric currents passing in the magnetising coils is first transformed into mechanical energy, and then into heat. But this, in the writer's opinion, furnishes the clue to the connecting link that we are seeking—the link joining the two forces.

In order to grasp the idea that the writer has formed on the subject, it will be necessary to make a somewhat bold, but, he believes, a grand conception. When the atoms of what we know as our earth, the planets, our sun, and the other heavenly bodies, were passing from the gaseous or nebulous state to the solid, each group of atoms combined in some particular manner, forming themselves into certain substances, according to the conditions surrounding each group and the forces acting upon them, and so the different chemical elements, with their different properties, came into existence. These properties would depend apparently on two things—the quantity of energy absorbed in each group of atoms, and the manner in which the energy was stored. This last—the manner in which the energy is stored—the writer takes to be simply the rate and form of the vibrations of which the energy stored in each element is composed. Thus, in the substance we know as zinc, the energy stored will consist of molecular vibrations at a certain rate, and in a certain manner—the molecules covering a certain path. In iron, the energy stored will consist of vibrations at a different rate from that of zinc, and again with a totally different path for their motion. In copper, again, the motion would appear to be at a different rate from that of zinc and of iron, and with a path differing from either, but more like that of zinc than that of iron. It follows, if the above be correct, that what we know as chemical affinities are really only such affinities of vibration as we are familiar with in the case of sound.

As every student of acoustics knows, columns of air, say, enclosed in long jars, will only respond to particular notes that are communicated to them; to all others they are apparently dumb. So it would seem that when we say that zinc or iron has a strong affinity for oxygen, we merely mean that the periods of their vibrations—and the paths which their individual molecules take—are such as will readily coalesce to form what we call another substance, but which, if the motions were larger and those of bodies that we could see, we should call taking the form and the period of the resultants of the two motions.

Amongst other points, it may be noted that each substance, however simple, or however complex, has the property of selecting what portion of heat or light rays it will absorb and what portion it will reject, the latter portion determining by what colour, as we term it, the substance shall be known to the human eye. Of course we know that by colour we merely mean that the rays of light reaching our eye from a given body are vibrating at a certain rate. But it would appear that this question of colours like that of chemical affinity, and like that of columns of air, stretched wires, etc., is merely a question of the rates and the forms of vibration of the body upon which the light rays fall, and such of those of the light rays themselves as are able to coalesce, and that the colour and form assumed by the body is due to the resultant of these vibrations to the resultant rate and path taken by the molecules of the body. Colour contrasts and some of the well-known optical delusions well illustrate this. Among the numerous forms taken by different groups of atoms and their numerous properties, iron and its alloys, with cobalt and nickel, appear to have conferred upon them the peculiar property we know as magnetism—viz., the property of being double-ended—the two ends having opposite qualities, and the property of dissimilar ends attracting each other. This the writer conceives to be stored energy in the form of a vibration of a special time and form peculiar only to those bodies—iron, nickel, and cobalt—but more especially to iron. Oxygen, as we know, possesses magnetic properties in a very small degree, and it is a striking fact that one form of oxide of iron, Fe_3O_4, also possesses this same property, while the other compounds that iron forms with oxygen and with other elements do not. The writer interprets this fact thus: The molecules of the iron when pure, or when alloyed, are in a state of vibration at the special rate and in the special manner which gives rise to polarity and attraction between dissimilar poles. When combined with a certain

quantity of oxygen, that contained in the magnetic oxide, the resultant rate and form is sufficiently near to that of the iron itself to enable the molecules to respond to the force exerted by other magnets, though not so readily as iron would. When other proportions of oxygen or other elements are combined with the iron, the rate and form of the vibrations are so altered that they do not respond to the vibrations emitted by magnets, and have lost the magnetic properties. It appears to the writer that it is probable that magnetic vibrations within any magnet, or within any molecule of any magnet, are in the form of continuous waves from one end to the other, these waves being taken up by the ether surrounding the magnet or the molecule, and from it communicated to the next molecule, or to another magnet or another piece of iron, as a pushing or pulling force—what we call lines of force being merely the communication by the ether of this pushing or pulling force—the ether itself, of course, vibrating in unison with the magnet or the molecule it proceeds from.

Then as to how electricity is connected with magnetism. If Prof. Ewing's theory of magnetism is correct—and, as we know, it answers for all known phenomena—if we impart energy, or, in other words, molecular vibrations to the molecules of an iron bar, in a suitable manner, in a manner that they can accept, they are obliged to release themselves from their previous attractions for other molecules, turn themselves round in a particular manner, and send off their lines of force, their pushing and pulling forces, in front of and behind them. What takes place is, in the writer's view, the molecules of iron take up a position which is due to the resultant of the two sets of vibrations—those present in the molecules before the act of magnetisation, and those impressed by the electric current; both, of course, being modified by the vibrations of surrounding bodies. What the electric current does apparently is to communicate this energy to the molecules of iron, nickel, or cobalt, just in the form in which it will do that particular work within the bar—viz., the twisting of these molecules and the sending out of their pushing and pulling forces into the ether surrounding. The rate and form of vibration imparted by heat, as we know, not only will not effect this, but will actually extinguish the magnetism when already created, the resultant rate and form of the vibrations being evidently such as will not respond to the magnetic pushing and pulling forces.

We do not know whether the form of energy we know as sound can be converted into magnetic energy. Probably it can, but only after first being transformed into some other form. From mechanical energy in the form of impact, as we know, we can obtain a slight degree of magnetisation; but it is electricity that gives us the best results, because apparently its rate and form of vibrations are so allied to those impressed upon the molecules of the iron at their birth that the resultants of the two create the pushing and pulling forces we know as magnetic repulsion and attraction.

But how does the electric current do this? The writer has not yet dealt at length with the phenomena of electrical conduction in this series of articles, but it may be stated shortly that his view is that what we call conduction is merely the transmission of the vibration he conceives electricity to be, continuously through the mass of the conductor, and electromagnetism he conceives to be its transmission in waves surrounding the conductor. As he understands the matter, the transmission within the conductor is only a part of another wave, the difference being that the wave within the conductor proceeds onwards at a very different rate to the waves surrounding the conductor, while the waves surrounding the conductor and emanating from it are influenced by the rate and form of the vibrations already present in the molecules surrounding the conductor.

Given, then, a conductor, with a current passing through it, and a piece of iron in its neighbourhood, it will be remembered that the iron, if it is to be properly magnetised, must occupy a certain position with reference to the conductor. Waves of vibrations emanate from the conductor, circling round it in larger and larger circles, and on arrival at the iron, impress upon its molecules some of the energy of which they are possessed, and gradually as the molecules become possessed of more and more energy, more and more vibrations—now at a different rate and of a different form to that with which they were created—obliging them to turn round on their axes and to send out the push and pull vibrations already referred to, or, as we say, to become magnetic.

EPSTEIN ACCUMULATORS.

The following report, dated the 24th June, 1893, has been made by Messrs. H. Alabaster, Gatehouse, and Co. on the Epstein traction accumulators :—

The Epstein accumulators are formed by direct oxidation without the use of paste; they are simple, easily managed, and apparently very reliable; the plates are very strong, and few in number, the reduction of the component parts constituting a great advantage, especially when employed for traction work.

Two sets of tests have been made—with a five-cell traction battery hermetically sealed to prevent the escape of solution, and on a one-cell accumulator (open) supplied to show the construction of the cells in the five-cell battery. The plates are of the Planté type of substantial construction, having their surfaces grooved, thereby increasing the active surfaces of the materials.

The following are the particulars of the open cell :

	Weight lb.
One positive plate, 19⅝in. by 8in. by ⅜in.	14
Two negative plates, 19⅝in. by 8in. by $\frac{5}{16}$in.	17½
Ebonite cases, 21⅞in. by 11in. by 2in. by ⅛in.	3½
Solution	12
Wood box containing ebonite cell (this is not usually supplied, and the weight should therefore be deducted)	10
Ebonite insulators	½
Total	57½
One five-cell traction battery	244
Average weight per cell	48·8

These cells, which were represented as being capable of developing 90 ampere-hours at a 30-ampere rate, we received ready charged on June 16, 1892, and remained at rest until September 7, before the first discharge, when they were joined in series and gave out 71·273 ampere-hours and 801·494 watt-hours. They then received one charge of 100 per cent. more current than their specified output, followed by a series of discharges at 30 ampere rate, and charges of 5 per cent. above their output at the same rate, until September 10, when after a charge of 95 amperes and 1,291·4 watt-hours they were left at rest until November 18 (during which time no special care was taken to insulate them), when they gave out 55·65 ampere-hours and 600·59 watt-hours, being 55·59 per cent. quantity, and 45·51 per cent. energy efficiency of the charge they received on September 10. This was followed by consecutive tests, terminating on November 24.

The following is the mean of the observations made during the two experiments :

Charge		Discharge		Efficiency		
Ampere-hours.	Watt-hours.	Ampere-hours.	Watt-hours.	Ampere-hours.	Watt-hours.	Dates.
94·9	1,367·92	89·72	1,058·80	94·58	77 69	Sept. 7-10
94·8	1,351·63	91·42	1,058 99	96·44	78·44	Nov. 18-24
		Mean 90·57		176·50 per cell.		

It therefore follows that

176 5 watt-hours corresponds to 5·605 watt-hours per lb. of combined + and – plate.
" " " " 12·61 " " of + plate.
" " " " 3·618 " " of cell.

And therefore—

30-ampere rate corresponds to 0·9528 ampere per lb. of combined + and - plate.
" " " 2·143 " " of + plate.
" " " 13·51 " " sq. foot + plate.
" " " 13·51 " " " – plate.

It will thus be seen from these results that so far as regards the behaviour of the accumulators when at rest, they act in every way as represented by Mr. Epstein, even to the remarkably good results obtained after long intervals of rest, and they confirm the very favourable report made on the Epstein accumulator, in July of last year, by Prof. W. E. Ayrton, F.R.S.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

140 SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

HONOUR TO WHOM HONOUR IS DUE.

To-day the patent for the incandescent lamp expires. Although the general feeling may be one of thankfulness that now these lamps will be placed on the market with only trade profits, there must be another feeling amongst the few who wonder how far the anathemas of competitors mislead the world. As electrical engineers, let us consider for a moment what has made our industry possible—yes, possible; for without two patents the industry would not exist. If it were useful, we might fill a whole number with opinions expressed by prominent men as to the possibilities of electric lighting prior to 1880. A careful study of the Blue-book issued in 1879, containing the evidence before the Select Committee of that year, will sufficiently prove the case we bring forward. The birth of an electrical industry is due to M. Gramme. Whatever credit we may give to the constructors of magneto and dynamo machines before Gramme will not affect the fact that he was really the first to construct a machine to suit all practical requirements. But the machine of Gramme would have failed to build up an industry had not Swan and Edison come forward with an incandescent lamp. The development of the Gramme dynamo combined with the development of the incandescent lamp has given us an industry the bounds of which are in the unknown. Ought we to grudge Gramme the money value of his patent, or ought we to grudge Swan and Edison the money values of their patents? Whatever these men have received—and doubtless it is much less than the world generally supposed—it is no more than their due. We say the amount is less than one generally supposes, because a close examination of the facts will show that so far as the Swan-Edison Company is concerned, prosperity did not dawn for them till the second half of the period during which this patent that now lapses had run. The memory of the world is short. The gratitude of shareholders is shorter. An extra half-year before dividends are paid is enough to cause dictionaries to be ransacked for adjectives to throw at directors; a diminution of dividend, and the same state of things prevails. As electrical engineers, our readers are mostly neither directors nor shareholders, and can therefore without company feeling join in the praise of men who have made possible an industry which numbers them within its borders. We can express a hope that the pecuniary reward these inventors have reaped has proved satisfactory to them. The life of a successful inventor is not altogether to be envied while his patents run. The world has no soft words for him: he is everything bad that a vocabulary can be made to indicate. His friends praise him to his face for what they can get, while his would-be competitors think burning at the stake a mild correction. Could Messrs. Swan and Edison have collected the sweet words uttered because of their so-called bloated monopoly, the collection of language would be unique.

It will be unnecessary to expatiate on the condition of the industry now; let us briefly examine the state in 1879 as portrayed by the Blue-book. We find in the appendix pictures of

Gramme machines, of Lontin's machines, of Jablochkoff's lamp, of the Rapieff lamp, and of the Wallace farmer machine and lamp. Where are these, except the Gramme, in fourteen years? In the two hundred and forty odd pages of the Blue-book there is no mention of an incandescent lamp such as we know it. A few of the questions and answers will be interesting. Thus Prof. Tyndall in his evidence:

50. Supposing that you have a light produced by one current, say of ten thousand candles, can you divide that into ten lights of a thousand candle-power each from the same electric current?

I do not think so.

51. In fact, at the present moment there is nothing, either in science or in practice, to show that you could do that without loss?

I think not.

The late Mr. C. W. Siemens gave the following replies to questions:

259. Has your attention been called to some of the more recent experiments of Mr. Edison, and to the success which he is stated to have achieved in subdividing the light, and making it applicable for rooms and dwellings, and so on, with great ease and cheapness?

I have, and I think Mr. Edison can, no doubt, produce by his means a very steady and possibly an agreeable light.

260. And a cheap light, he claims, I believe? Dynamically speaking, I think he has to prove his case as yet.

Our experience, as far as I can judge from my own, leads me to an opposite conclusion.

297. You would say that for such purposes as footlights and sidelights, which require constant modification of the light, at present at any rate, whatever your experience may lead you to in the future, the electric light is hardly a suitable light?

Such a light, for instance, as Mr. Edison proposes now, I think would be much more controllable in that respect than the electric arc. The electric arc cannot be varied in its intensity and brilliancy so readily as gas; but if the light is produced by igniting a piece of iridium or platinum wire, then it is easy enough to modify the current so as to give only a small amount of radiated light.

298. But up to the present, at any rate, lighting with platinum or iridium has hardly gone beyond the experimental stage?

Certainly not.

Mr. Conrad Cooke said:

425. Dr. Siemens, in referring to Mr. Edison, who is credited with having recently invented a machine for subdividing the light, expressed some doubt on the subject, and stated that he thought that it was not as promising as the reports indicated. Do you know anything about that?

We really know very little at all about it. A few newspaper paragraphs have appeared on the subject, and I have been very much interested, as everybody has. His nephew told me himself that he has seen, I think, over two hundred lights on one circuit. I must say I should like to see it myself, and that is all I can say.

Mr. W. H. Preece said:

541. Speaking of the lighting of a street of 1,000ft. long, your estimate was that forty lamps of fifteen candles each, giving a total of six hundred candles, would light the street better than one electric light of six thousand candles?

So my calculation comes out; but, as I say, it is so startling, and so curious, that I am also inclined to think that there must be some mistake somewhere. I have got it nearly ready for the *Philosophical Magazine*, but it is so curious that I do not like to publish it unless I verify it a little further.

We will not multiply quotations further, but simply state that throughout the evidence there is no indication of certainty of what was then termed the subdivision of the electric light. All the evidence which contained no uncertain sound was to prove the suitability of the arc light for almost every purpose—to praise it as the forthcoming light, and to contend that it would prove to be divisible and useful for interiors as well as for exteriors. Those doctrines are now exploded—they were exploded before the next report issued by Parliament of the Select Committee in 1882. In fact, the question was practically solved in 1879, but none of us knew with certainty. Rumours, fast and furious, flew about, but the incandescent light was not seen by any of the moving spirits in the Select Committee till months after the issue of the report. Fourteen years have passed since November, 1879, and what a fourteen years in the history of electric lighting! What is the number that owes daily bread to Swan and Edison? Arc lighting no doubt would have developed, but its powers to create an industry would have been small compared with those of incandescent lighting. Therefore, while being thankful that the end of the patent monopoly has come, and that the manufacture is open to the world, we should not forget nor be slow to admire the work of the men who made these things possible.

ELECTRIC FIRE-ENGINES.

Most of our readers will recollect that a fire-engine worked by an electric motor was exhibited at the late Crystal Palace Exhibition. We think it was one of Messrs. Siemens's motors, but at any rate it was daily shown in action throwing water to the Palace roof. The idea seems also to have reached America, though there the prior work in England seems to be unknown or ignored. If, however, the energy of our cousins on that side causes more attention to be paid on this side to an application of the utmost importance and simplicity, we shall not complain. It is extremely difficult to convince users of any apparatus that improvement is possible. They know what the old will do, and prefer to let someone other than themselves try the new. What are the advantages of an electric fire-engine, and where might it at once be useful? We think the advantages very great; it would be cheaper, would be lighter, would be

smaller, would work without fire and smoke, and be quite as effective as the steam fire-engine. It might with advantage be obtained for factories requiring an engine and running their own electric light installation, or for areas where electric current could be obtained from street mains. There would be no getting up steam, but simply the pushing home of a plug into proper contact-pieces. These fire contact plugs could be as numerous as the junction-boxes in an electric light system—more numerous if desired—and add little to the cost of the electric mains, and interfere nothing with their efficiency. Electric lighting is becoming so common and so largely supported by local authorities, that when the question of a new fire-engine arises it might be well to consider the one worked by an electric motor. Perhaps the difficulty of motor comes in. Some authorities use a continuous current, some an alternate current, and ordinarily a motor will be constructed for use by one or the other, not for both; but there are motors said to work equally well with either kind of current. Therefore, if such motors can be constructed of the size required, one obstacle is removed. It will be well if manufacturers keep this application of electricity in view, and push what may prove a most lucrative branch of business.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC TRAMWAYS.

SIR,—Though the era of electric traction as applied to tramways has not yet begun in England, it nevertheless ... reached a very critical stage in its history. The recent decision of the Parliamentary Committee on earth returns has opened up the way, and some development of electric traction may reasonably be expected. The results of the early attempts will be watched by tramway managers with interested not severely critical eyes. The extraordinary success which has attended the introduction of electricity on the street railways of this country has led English electricians to lay before the tramway managers very sanguine estimates of the effect of supplanting horses by electricity, more especially as regards the cost of running the cars. Should these early attempts not meet with the success so confidently predicted, the confidence of the tramway officials will be almost irretrievably undermined: they will come to the conclusion that the claims advanced for the cheapness of electric cars are on a par with those so often and so recklessly advanced for the cheapness of the electric light, and it will not be much use talking electricity to them then for some few years to come, nor will elaborate explanations as to why these particular lines were unsuccessful carry much weight with them. It is not, therefore, without reason that I have said that the present time is critical. A mistake now would be well nigh fatal, but, fortunately, we have one great precedent to guide us—America. Are we going to avail ourselves of the varied experiences so dearly bought by that progressive country, and now laid gratis at our feet, or are we going to let our national pride intervene and send us groping blindly in that unknown region that is studded with expensive pitfalls, are we, in fact, to work in series with America, or in a kind of belated parallel? This is an age of common sense, and I think we shall choose the former alternative.

To what points, then, shall we turn our attention? By far the most important is the absolute supremacy of the trolley. When I first came to this country I had a vague idea that there were several systems of electric traction—trolley, conduit, and storage batteries—and that none could be said to have gained the victory over the others. This was, I believe, the opinion prevalent in England at the time, and so far as I can judge seems to be so still. Only a few weeks ago, the *Electrical Engineer* in an editorial recommended the use of the conduit system for a part, at least, of the Leeds tramway system. I do not like to say that this suggestion was little short of criminal, as that might be looked upon as an exaggeration, but it would not be far, nevertheless, from expressing my opinion. What has been the experience of the rest of the world in the matter? The history of the trolley in this country has been one triumphal march from Maine to California—or perhaps I should say from California to Maine. Throughout all the land there is scarcely a town of importance that is not enlivened by the peculiar buzz of the passing trolley; the financial results, needless to say, have been equally satisfactory, otherwise the system could not have grown as it has. Five years ago the trolley was practically unknown in America: to-day one might almost say there is scarcely anything else; and in trying to grasp this statement it should not be forgotten that whilst in England only large cities have any tramway accommodation at all, in this country every village has it, or must be content to tolerate the ridicule of its neighbours.

In striking contrast is the history of the conduit and the storage battery. Here, as elsewhere, there is a strong opposition to the introduction of the overhead trolleys into a city where they have not previously had any, though none object afterwards, as they are then compelled to realise how greatly the advantages outweigh the disadvantages. This opposition has resulted in the devotion of an immense amount of time, ingenuity, and capital to the perfection alike of storage battery and conduit, yet there has been nothing but failure; occasionally a storage battery car runs successfully, extravagant claims are made; the Press, especially the lay Press, enthuses, and then the storage battery car passes out into that oblivion where many a storage battery has preceded it, and the trolley quietly takes its place. The conduit has been tried again and again, and though run by men of long experience in the electric railway business, it has been even less successful than the storage battery. I know of only one conduit road now running in this country, that at Washington, and that has not yet passed through a winter. The Budapest road is the solitary example of success that has crowned the efforts of those who have pinned their faith to the conduit. Whilst, then, the trolley has proved, I think I am justified in saying, the most extraordinary success in the history of the commercial world, the history of its rivals is nothing but a succession of gloomy failures. It is, therefore, with all the emphasis in my power that I protest against the use of either storage battery or conduit at this critical time. Should the conduit be introduced, its unreliability, its great cost, both initial and running, will bring almost inevitable failure in their train, and electric traction will have received a blow under which it may well reel.

Another point to which I wish to direct attention is the voltage. I think a determined stand should be made before the Board of Trade to induce them to allow the use of 500 volts. I do not think the Board of Trade are as old-womanish as some would have us believe. Is it realised that the electric cars of this country are carrying passengers at the rate of many hundreds of millions (about 900,000,000, I believe) annually—that is to say, about the same number as all the steam railroads of England put together—that the voltage is universally 500, and that no one has ever yet been killed by a shock from a trolley wire; indeed, it is a matter of common knowledge to electricians that a 500 volt shock, though anything but pleasant, is in no way dangerous. Now, all this is no mere theorising; it is the everyday experience gained in the transportation of countless millions. I think that if this state of affairs were put fairly and squarely before the Board of Trade, they could not but consent to the use of 500 volts.

These are but a few of the many points upon which I could enlarge, but I fear I have already trespassed greatly on your space, for which the vital importance of the subject must be my excuse.—Yours, etc.,

Detroit, Mich.

NORMAN WHICHELLO.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE IV.

(Continued from page 436.)

High and Low Pressure Systems.—Systems of hydraulic transmission are of two distinct types. First, there are systems which, for convenience, may be termed low pressure systems, with reservoir storage. In these the working pressure is fixed by local conditions, especially by conditions determining the site for the reservoir. Generally, the pressure is not more than 400ft. to 600ft. It is the reservoir storage in these systems which more than anything else, makes them suitable for the supply of power for all ordinary industrial purposes, for driving factories or electric light stations, for instance, involving a large continuous demand for power extending over considerable periods of time. Secondly, there are systems which, for convenience, may be termed high pressure systems, with accumulator storage. The pressure in these systems is usually 700lb. to 800lb. per square inch, or 1,600ft. to 1,800ft. of head. These systems, in which the reserve of energy is limited in amount, are most suitable for working cranes and lifts, hydraulic presses, and similar intermittently working machines.

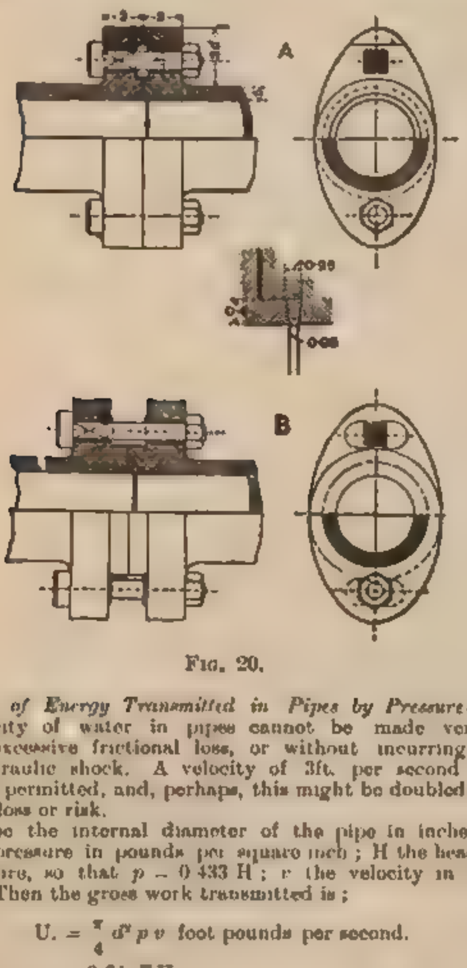

FIG. 20.

Amount of Energy Transmitted in Pipes by Pressure-water.—The velocity of water in pipes cannot be made very great without excessive frictional loss, or without incurring danger from hydraulic shock. A velocity of 3ft. per second is very commonly permitted, and, perhaps, this might be doubled without excessive loss or risk.

Let d be the internal diameter of the pipe in inches; p the working pressure in pounds per square inch; H the head due to the pressure, so that $p = 0.433$ H; v the velocity in feet per second. Then the gross work transmitted is;

$$U. = \frac{\pi}{4} d^2 p v \text{ foot pounds per second.}$$

$$= 0.34\, d^2 H v \quad ,, \quad ,,$$

or in horse-power—

$$H.P. = .001428\, d^2 p v$$

$$= .000618\, d^2 H v$$

GROSS HORSE-POWER TRANSMITTED BY DIFFERENT MAINS.

Low Pressure System.—Head, 500ft.

Diameter of main in inches.	Gross h.p. transmitted.
9	73
12	133
18	300
24	533

High Pressure System. Pressure, 750lb. per sq. in.

Diameter of main in inches.	Gross h.p. transmitted.
3	29
6	116
9	260
12	463

At 3ft. per second, and with a pressure of 500ft., as at Zurich, a 12in. main would transmit 133 h.p., and a 24in. main 533 h.p. Mains of this size can be used with such a pressure. With the high pressure of 750lb. per square inch, and at the same velocity, as in the case of the London hydraulic power system, a 6in. main transmits 116 h.p., and a 12in. main, if it could be safely used, would transmit 463 h.p. The horse power is gross horse power, without allowing for loss in the motors.

In neither the high pressure nor the low pressure system is the amount of power which can be transmitted by a single main very great. This involves a definite limitation of hydraulic systems. They are best adapted for driving machines working only a fraction of the 24 hours, or for motors for small industries not requiring a great amount of power.

Loss of Pressure due to Friction in the Mains.—At a velocity of 3ft. per second the loss of pressure per mile of main, due to friction, is about 18lb. per square inch in a 6in. main; about 9lb. per square inch in a 12in. main, and about 4½lb. per square inch in a 24in. main. These losses are insignificant on a high-pressure system, and not very important on a low pressure system, with distances of transmission such as are practically attempted. The losses of energy due to distribution in an hydraulic system, apart from those due to the pumping or motor machines, are so small in most cases that they may be dismissed from consideration without any very serious error.

The following table gives the loss due to friction at a velocity of 3ft. per second per mile of main:

Diameter of main in inches.	Loss due to friction per mile—In feet of head. Clean.	Encrusted.	In lbs. per sq. in. Clean.	Encrusted.
6	35·5	70·9	15·37	30·70
12	16·3	32·5	7·06	14·07
24	7·4	14·8	3·20	6·41

For rough calculations, the loss of pressure per mile may be taken at 107 d lb. per square inch. The percentage loss per mile, reckoned on the working pressure, is as follows:

NEW AND CLEAN PIPES.

Diameter in inches.	For pressure in feet of— 100	250	500	1,000	1,600
6	35·5	14·2	7·1	3·5	2·2
12	16·3	6·6	3·3	1·6	1·0
24	7·4	2·8	1·4	0·7	0·5

With encrusted pipes the percentage loss is double as great. The loss in any case is not very important for working pressures of more than 500ft. of head and distances of transmission likely to be attempted. For small working pressures, or greater velocity in the main the frictional losses become much more important. That is one reason why high working pressures are advantageous in hydraulic systems.

Considerations arising out of the Strength of the Pipes.—In all hydraulic systems at high pressure in this country cast-iron pipes have been used, with a peculiar flanged joint having two bolts. Mr. Ellington's experience in London shows that a main of this kind can be made absolutely tight and free from leakage. The largest mains used are 7½in. in diameter. The working stress in the metal, due to the water pressure, is 2,800lb. per square inch. The mains are usually tested to a water pressure of 2,500lb. per square inch before laying, and to a pressure of 900lb. to 1,600lb. per square inch after laying.

Fig. 20 shows at A the form of joint used by Lord Armstrong, and at B a modification introduced by Mr. Ellington. The joint is made tight by a guttapercha ring. The flanges are placed in a horizontal position in laying. Mr. Ellington found that fractures in the pipes occurred by the breaking off of one of the lugs for the bolts. By placing the lugs a little further back on the pipe the strength was found to be greater. Probably the slight flexibility of the pipe line that this form of joint allows is an important element in its success.

Probably, solid-drawn steel pipes would now be used, if a suitable joint for them could be devised. Such pipes were proposed to be used in a project submitted to the Niagara Commission by MM. Vigreux and Feray. For steel pipes a stress of 15,000lb. per square inch might be allowed; and the use of such pipes would much extend the capabilities of the high pressure hydraulic system. On low-pressure hydraulic systems ordinary socket pipes can be used.

Considerations arising out of the Weight and Cost of the Distributing Mains.—For pipes of equal strength, and at a given limiting velocity of flow, the weight of mains is simply proportional to the horse power transmitted. Hence so far as cost of mains is concerned, the low pressure system is as economical as the high-pressure system. No doubt, however, if all practical exigencies are taken into account the cost of mains is somewhat greater for low pressure than for high pressure systems.

Considerations arising out of the Type of Motors Driven by the Pressure-water.—On high pressure systems the motors used are almost exclusively pressure engines—that is, motors with reciprocating plungers or pistons. Such motors become extravagantly costly for low working pressures. The greater the working pressure, the more conveniently and cheaply is the power produced by motors of this class. Hence the general adoption of pressures of 700lb. to 800lb. per square inch in high pressure systems. The pressure-engine type of motor is extremely convenient for lifting machinery and hydraulic presses, and even for rotative motors of small size. It is not nearly so convenient when a large amount of power is to be developed continuously for driving a factory. For that purpose turbine motors are much better, being cheaper and more easily regulated. It is true that some of the newer types of turbine—such as impulse turbines and Pelton wheels—can be used even at pressures of 800lb. per square inch. But, on the whole, low-pressure reservoir systems are better suited to cases where power has to be developed by turbines.

* Howard Lectures delivered before the Society of Arts.

High Pressure Systems.

*The Hull Hydraulic Power System.** This was the first scheme for distributing power hydraulically to many consumers. The principal main is 6in. in diameter and 1,485 yards in length. The joints were flanged joints, with a guttapercha ring of the kind generally used since. The pumping station is arranged for four 60 h.p. engines, of which two have been erected. Each engine delivers 130 gallons per minute at 700lb. per square inch pressure, corresponding to 63.6 effective horse power. There is an accumulator 18in. in diameter and 20ft. stroke, loaded to 610lb. per square inch. The charges were originally intended to be £52 for one crane per annum, and less for several cranes in one warehouse. The charges are, however, by quantity of water supplied as measured by meter. The minimum charge is £8 per machine per annum. The charge by quantity of water used ranges from £8 per annum for 16,000 gallons, or less, to £200 for 1,200,000 gallons, with special rates for greater quantities. The following short table will give an idea of the way the charges are graduated.

Consumption of water per quarter. Gallons.	Charge per quarter. £ s. d.	Charge per 1,000 galls. supplied. Shillings.
4,000 or under	2 0 0	10.0
9,000 to 10,000	3 10 0	7.0
49,000 to 50,000	12 10 0	5.0
99,000 to 100,000	20 0 0	4.0
199,000 to 200,000	35 0 0	3.5
299,000 to 300,000	50 0 0	3.3

The charge in excess of 300,000 gallons per quarter is 2.5 shillings per 1,000 gallons. For 500,000 gallons per quarter, 2.5 shillings per 1,000 is charged for the whole supply.

The London Hydraulic Power Company.† An Act was obtained in 1871 for supplying hydraulic power in London. The rights conferred by the Act remained dormant until resuscitated by Mr. Ellington in 1882. The present company was constituted in 1884. In 1887 25 miles of pressure main had been laid in London streets, and at the present time there are nearly 60 miles of pressure mains. These extend from the West India Docks and Wapping on the east, to Kensington on the west; from Mint street, south of the river, to Clerkenwell and Old street on the north.

There are three principal pumping stations: one at Falcon Wharf, a short distance east of Blackfriars Bridge (800 i.h.p.); another at Millbank, Westminster (600 i.h.p.); and one at Wapping (1,200 i.h.p.). A fourth station, in the City road, is in course of erection (1,200 i.h.p.). The aggregate power of all the stations, when complete, will be 3,800 i.h.p., of which one third is reckoned as reserve power in case of repair or accident.

At Falcon Wharf and Millbank all the water is taken from the river, but it is filtered before it is pumped into the mains. At Wapping, part is taken from the London Dock, part from a well. After use by consumers it flows into the sewers. The power is available for use night and day all the year round. It is largely used for lifting machinery and for presses and pumps. The company claim that it can be used for electric lighting of particular establishments and for extinguishing fires. For this last purpose Mr. Greathead's injector hydrant or hydraulic intensifier is applied. A small jet of water from the high pressure mains is made to intensify the pressure of a larger jet drawn from the ordinary town mains. A fire stream is so obtained capable of reaching the top of high buildings without employing a fire engine. In 1892 there were 1,696 machines worked by pressure water from the company's high pressure mains, consuming 6,000,000 gallons per week. The quantity of water used by each consumer is measured by a meter on the exhaust pipe of the machines driven. Parkinson's meter is most used. Siemens's turbine meter is used to some extent, but it is inaccurate under the sudden fluctuations of discharge which occur. Kent's positive meter is also used.

At Falcon Wharf there are four sets of compound pumping engines capable of indicating 200 i.h.p. They are vertical, with one high and two low pressure cylinders, and a pump plunger directly connected to each piston. At 200ft. of piston speed per minute each set of engines will deliver 240 gallons per minute, at 750lb. per square inch pressure, into the accumulator. This corresponds to 120 effective horse power. A nine hours' trial of one set of engines was made in 1887, the engine running at constant speed and the coal used being seaborne small coal. The boilers are provided with an economiser.

Trial of Hydraulic Pumping Engines.

Total indicated horse-power	178.5
Piston speed, feet per minute	221.4
Steam pressure, pounds per square inch	82.5
Evaporation (from and at 212deg.) per pound of fuel, pounds	10.59
Feed water per indicated horse power hour, pounds	19.79
Coal per indicated horse power hour, pounds	2.19
Accumulator pressure pounds per square inch	750
Effective horse power, calculated from water pumped, allowing 5 per cent. slip	139
Mechanical efficiency of engine	0.78
Water pumped per minute (gallons)	205.7

The engines consume, in ordinary work, 2.93lb. of coal per indicated horse power, which is greater than the result given above, in consequence of the fluctuation of speed.

There are two accumulators at Falcon Wharf, with rams 20in. in diameter and 23ft. stroke. Each accumulator has a capacity of storage equal to 2.4 horse power hours. The filters are Perrett filters, constructed by the Pulsometer Company. The filtering material is compressed sponge. It is cleansed every four to six hours by reversing the direction of flow, and by alternately compressing and releasing the pressure on the sponge.

The pumping station at Wapping is a more recently constructed and larger station than that at Falcon Wharf. The water pumped is obtained partly from a well sunk into a gravel bed, partly from the London Dock. The pumping from the well into a tank over the boiler house is effected by low lift pumps worked hydraulically by the pressure water. From this tank it passes through "Torrent" filters constructed by the Pulsometer Company to underground reservoirs. From this it is lifted by the condenser circulating pumps to another tank above the boiler house, whence it is pumped into the mains. The reservoir capacity is 800,000 gallons. The engine house contains six sets of vertical inverted triple expansion engines with cylinders 15in., 22in., and 36in. diameter, and 24in. stroke. Each piston drives a single-acting plunger pump, with ram 5in. diameter, direct from the cross head. The working steam pressure is 150lb. per square inch, and the hydraulic pressure 800lb. per square inch. Each set of engines will deliver 300 gallons of water per minute at a piston speed of 250ft. per minute. All the cylinders are jacketed.

In a test trial the engines are stated to have worked with 14.1lb. of steam, and 1.27lb. of Welsh coal per indicated horse-power hour. The water passes from the pumps to two accumulators with rams 20in. diameter and 23ft. stroke. One of the accumulators is loaded to a slightly heavier pressure than the other, so that one accumulator rises a little in advance of the other. The more heavily loaded accumulator automatically shuts off steam when at the top of its stroke. A good description of these works will be found in *Engineering* for January 20, 1893.

Charges for Pressure-water for Power Purposes.—The London Hydraulic Company make a minimum charge of £1. 5s. per quarter per machine. For consumers using more than 3,000 gallons per quarter, there are graduated charges, of which the following short table gives a sample.

Gallons used per quarter.	Charge. £ s. d.	Cost of pressure water per 1,000 gallons. Shillings.
3,000, or under	1 5 0	8.3
10,000	3 10 0	7.0
50,000	12 10 0	5.0
100,000	20 0 0	4.0
200,000	31 5 0	3.1
300,000	42 10 0	2.8

For an excess over 300,000 gallons per quarter is charged at 2s. per 1,000 gallons. Consumers using more than 500,000 gallons per quarter are charged 2s. per 1,000 gallons all round. Rates are further reduced for still larger quantities, and the minimum rate is 1.5s. per 1,000 gallons.

With these charges the cost of power for the kind of work for which an hydraulic system is best suited is small. Thus it is often less than one farthing per ton lifted 50ft. On the other hand, it is necessary for the purpose of this treatise to consider the cost of power distributed by different methods on some common basis. It is almost unavoidable to take the cost of power exerted continuously through the working day. If the cost of power supplied by the Hydraulic Power Company is reckoned for machines working 3,000 hours per year, then the cost is larger than that of power obtained in other ways. The comparison of the cost so reckoned is instructive, although it may be in fairness pointed out that Mr. Ellington, in his paper, stated that he had never advocated the supply of power for continuous driving engines to any large extent.

To obtain one effective horse-power during 3,000 hours per annum, allowing an efficiency of 80 per cent. in the motor, 437,500 gallons of water are required. Hence, a consumer taking 50,000 gallons per quarter would get the equivalent of 0.457 effective horse power for 3,000 hours, and would pay for it at the rate of **£109 per horse-power per annum.** A consumer taking **300,000** gallons per quarter would get the equivalent of 2.743 effective horse power for 3,000 hours, and would pay at the rate of £62 per effective horse power per annum. A consumer taking 500,000 gallons per quarter would get the equivalent of 4.573 effective horse-power for 3,000 hours, and would pay at the rate of £43. 15s. per effective horse power per annum. It must be remembered that this is the cost for pressure water only, and does not include meter rent or interest on the cost of the motors.

The Liverpool Hydraulic Supply System.—In Liverpool, pressure-water from the town mains was used for working hydraulic cranes as early as 1847. From an interesting paper by Mr. Joseph Parry* it appears that the use of hydraulic power in this way made very slow progress. In 1877 the number of hydraulic machines supplied from the town mains was 89. At the present time there are 162 machines worked by water from the town mains, consuming 125,600,000 gallons per annum. Taking the mean pressure at 70lb. per square inch, this is equivalent to 82,710 effective horse power hours, or to 27 effective horse power for 3,000 hours in the year—a rather insignificant amount. The average charge for working a goods hoist is £13 per hoist per annum, or only 10d. per hoist per day—a small cost for the convenience afforded. The charge for water is 7d. per 1,000 gallons. At this rate the charge is equivalent to £120 per effective horse power per year of 3,000

* See Robinson, *Proceedings* Institution of Civil Engineers, vol. xlix.

† The account of the London hydraulic system is taken partly from a paper by Mr. E. B. Ellington, *Proceedings* Institution Civil Engineers, vol. xciv., partly from the reports of the company.

* "The Supply of Power by Pressure from the Public Mains." *Proceedings* Institution of Mechanical Engineers.

hours. Experiments on the quantity of water used by some hoists showed the cost to amount to from 6d to 10d. per ton lifted 50ft.

There is also in Liverpool a high pressure system, which is to be extended. Experiments with some hoists worked on this system showed the cost to be from 1½d. to 2½d. per ton lifted 50ft. Mr. Parry comes to the conclusion that hoists worked from the town mains cost more than those on the high pressure system when the charge for water on the high-pressure system does not exceed 5s. per 1,000 gallons.

The Birmingham Hydraulic Power System.—In Birmingham, as in Liverpool, water has been supplied from the town mains to work lifts. In 1888 there were 61 lifts and hoists thus worked, using 80,000 gallons per day, and yielding to the Water Committee of the Corporation about £1,000 a year. Since that time a high pressure system has been carried out, which has the peculiarities that it belongs to the Corporation, and that the pumping is done by gas engines.*

At the pumping station there are three sets of triple hydraulic pumps, working to a pressure of 730lb. per square inch. These are driven by three Otto gas-engines, nominally 12 h.p., 20 h.p., and 20 h.p., but capable of developing an aggregate of about 100 h.p. Ordinary lighting gas is used. The pumps deliver into two 6in. mains. There are two accumulators, with 20in. rams and 20ft. stroke. A small Brotherhood engine, worked by the pressure-water, is used in starting the gas engines.

Manchester Hydraulic Power Supply.—At Manchester a combined scheme for supplying electricity and high pressure water is being carried out. A pressure of 1,000lb. per square inch in the hydraulic system is to be used. It is hoped that there will be economy in working the electricity and pressure-water supply from the same station.

LOW PRESSURE HYDRAULIC SYSTEMS.

The Zurich Works.—The Zurich installation is a complex and very interesting one.† It was the earliest example in Switzerland of the application of hydraulic power, partly to pump a supply of potable water, partly to furnish motive power from the same central station. It has grown gradually, and of late has been greatly extended. It comprises machinery driven by turbines for furnishing (*a*) a water supply to the town of Zurich; (*b*) a supply of motive power transmitted by wire rope; (*c*) a supply of motive power transmitted by comparatively low pressure water from the town mains; (*d*) a supply of motive power transmitted hydraulically from a special reservoir at comparatively high pressure; (*e*) an electric central station also driven by water power.

When the works were first established the water supply of Zurich was obtained from a filter in the bed of the River Limmat, near its exit from the lake. This water was pumped by turbines erected a little further down stream. There being surplus water power, a telodynamic transmission was erected, and part of the motive power was distributed to factories along the river side. In 1884 the quality of the water was found to be inferior. After extensive investigations, it was decided to obtain a new supply of potable water from an intake in the lake, and to use the old water supply for motive power purposes only.

The fall available in the Limmat at the pumping station and the available volume of flow are as follows:

	Fall.	Volume of water flowing in the river	Gross water H.P.
	Feet.	c. ft. per sec.	H.P.
High-water level in summer	4.92	2,295	1,300
Mean " " "	8.20	1,660	1,570
Low " " winter	10.50	1,059	1,280

The effective power delivered by the turbines in the river is as follows:

	H.P.
For pumping filtered potable water	237
Supplying motive power by pressure water	128
Driving the wire rope transmission	227
Supplying hydraulic motive power for electric lighting station	444
Total	1,036

There are two reserve steam engines of 300 i h.p. each, to provide for a deficiency of water power.

At the pumping station there are eight pressure (Jonval) turbines, working up to from 96 h.p. to 100 h.p., according to the state of the river. There are also two newer turbines of about 175 h.p. each. The turbines have vertical shafts, and each pair drives, by bevel wheels, a common horizontal shaft, which runs at 50 revolutions per minute in the case of the earlier turbines, and at 66 revolutions per minute in the case of the two last erected. From these shafts a horizontal main shaft, 328ft. in length, and running at 100 revolutions per minute, is drawn. To this main shaft any of the pumps may be coupled. The earlier turbines cost, with gearing, about £12 per horse-power, the two larger turbines about £7 per horse-power. There are at present in operation seven sets of horizontal double-acting Girard pumps. The total pumping capacity is 8,143,000 gallons per day. The water for driving the turbines is obtained by a weir in the Limmat which deviates the water into a canal formed by a longitudinal embankment in the river. Sluices divide the head race channel from a tail race channel formed in a similar way. The pumps supply the following reservoirs:

	Height above pumps.	Capacity in c. ft. — Present.	Capacity in c. ft. — To be increased to.
Low level	164	205,000	–
Intermediate level	300	68,500	141,000
High level	485	10,600	21,190
Reservoir for high pressure power-water	528	353,170	529,000

From the town mains water is supplied to work 180 small motors. The total power thus supplied is about 187 h.p., and its cost is about 4.4d. per horse power hour. The principal supply of power, apart from that distributed by wire rope, is obtained from pressure water obtained from the old Limmat filter bed, and pumped to the special high level reservoir. This water is pumped chiefly during the night. The reservoir is about 6,000ft. from the pumping station, and is supplied by an 18in. main. The effective pressure at the motors is about 475ft., and the distributing mains have an aggregate length of 15,000ft. The charge for this pressure water for power purposes varies from 0.6 pence per horse power hour, when at least 50,000 horse power hours are taken in the year, to 1.25 pence per horse-power hour, when less than 20,000 horse power hours are taken in the year. For 3,000 working hours in the year the charge is from £7. 10s. to £16 per horse-power per annum. The water supplied in this way now amounts to 42,380,000 cubic feet per annum, yielding altogether about 900,000 horse power hours. The total receipts are £1,200 per annum, or 1.08d. per 1,000 gallons.

Besides this supply of pressure water to various consumers, the electric station is ordinarily to be driven by pressure water from the same high level reservoir. For this purpose two impulse turbines of 300 h.p. each have been erected for driving dynamos, and two smaller turbines of 30 h.p. driving exciting dynamos. Alternatively, if the supply of pressure water fails, the dynamos can be driven by the river turbines or by the reserve steam engines.

The Hydraulic Works and System of Hydraulic Power Supply at Geneva. There is now in operation at Geneva one of the most remarkable hydraulic power stations in the world. The water of the River Rhone, near the point where it flows out of Lake Leman, is employed to drive a number of large low pressure turbines, giving a total of 4,500 effective horse-power. These turbines pump pure water obtained from the lake into two systems of mains. The older of these termed the low-pressure system, the pressure at the pumps being 160ft. to 200ft., is an extension of a previously existing system of mains used for supplying potable water to the town of Geneva. Although some of the water pumped into this system is used for power purposes, it is chiefly intended to supply water for domestic and municipal purposes. The second system of mains, termed the high pressure system, the pressure at the pumps being 460ft., supplies potable water to some districts not reached by the low pressure system, but it is specially intended to afford a supply of water for motive power purposes to the entire area of the town. The demand for water, both on the low and high pressure system, is a fluctuating demand, large during the day, and very small during the night. Hence, if the turbines in the Rhone were employed solely in pumping into the mains, they would not be continuously working, and a large part of the water power of the Rhone would be wasted. To meet this difficulty, an important storage reservoir has been constructed at Bessinges, about four kilometres from Geneva. The turbines pump water up to this reservoir at night, and at times when the demand for power for other purposes is insufficient to keep them fully employed. The energy derived from water flowing back from the Bessinges reservoir through the high-pressure system represents parts of the water power of the Rhone which would necessarily have been wasted if this means of storage had not been provided.

The works at Geneva have been gradually developed under special local conditions. In spite of natural and political isolation, manufacturing industries have for centuries flourished at Geneva. That they did so is partly owing to the fact that cheap water power could be obtained by simple forms of waterwheel placed in the ample and rapid Rhone flowing past the town. An industrial quarter gathered along the banks of the river, and factories were built even in the stream itself. As the population increased a water supply was required. The small aqueducts of spring water became insufficient, and further recourse was had to the motive power of the Rhone. From the beginning of the eighteenth century waterwheels placed in the Rhone pumped a water supply into the town. Then arose antagonism to the utilisation of the motive power of the Rhone which, for two centuries hindered the progress of industrial enterprise at Geneva, and threatened at times to destroy the existing industries. The properties of riparian owners on the shores of Lake Leman were from time to time injured by the rising of the lake level. It was not unnatural that the landowners should attribute the disastrous inundations from which they suffered to the obstacles created at the outlet of the lake—that is, to the bridges and buildings, and especially the factories and waterwheels in Geneva. Complaints were addressed by the Canton Vaud to the Federal Government at Berne of damage caused by the works at Geneva. Then arose a question of arrangements necessary to regulate the lake level, and to facilitate in time of flood the discharge of the water. From 1875 the project of utilising the motive power of the Rhone took a new magnitude and importance from the combination with it of plans for regulating the level of Lake Leman, and so ending a long and bitter controversy.

Another local circumstance had great influence in determining

* See *Engineering*, February 12, 1892.

† See Preller on "The Zurich Water Supply Power and Electric Works." *Proceedings* Institution Civil Engineers, vol. cxi.

the ultimate form of the project for the utilisation of the motive power of the Rhone. In 1871, Colonel Turrettini,* the engineer under whose direction the present works have been constructed, had applied to the Town Council of Geneva to place small pressure engines on the mains of the then existing low pressure water supply. The plan of obtaining motive power in this way proved so successful and convenient that, in 1880 there were 111 motors at work, using 34,000,000 cubic feet of water annually, and paying a yearly rental for power water of £2,000. The cost of the power at that time to consumers was at the rate of £36 to £48 per horse-power per year of 3,000 working hours.

In 1878 a private firm asked the concession of a monopoly of the motive power of the Rhone, at Geneva, on condition of carrying out works necessary for facilitating the discharge from the lake, and regulating the lake level. A similar offer was made in 1881. But there grew up a feeling that such works should be carried out by and for the profit of the town itself. Finally, after many studies the contract was given by the Municipality in 1883 to M. Chappuis to construct under their direction the present works.

These works have cost, altogether, £283,000. Of this sum, a fraction has been paid by owners of land on the shores of the lake and part has been expended in constructing new sewers required in consequence of the alterations of river level. Deducting these items the cost of utilising the motive power of the Rhone has already amounted to nearly £200,000.

The scheme included the clearing away of all obstacles to the free flow of the river, and the division of the river, by a longitudinal embankment, into two portions, one forming a head race to the turbines, Fig. 21, the other—which was straightened and deepened—forming an outlet for the surplus water from the lake. Between the two divisions of the river bed are movable sluices which keep up the water in the head race channel, or discharge surplus water into the tail race channel, according to the condition of the lake. The scheme also included a complete reconstruction of the old pumping system for the low pressure water supply, the creation of the new system of high-pressure water supply, and the provision of motive power by hydraulic transmission to the industries of the town.

The Low Pressure River Turbines.—The turbine and pump house is placed at the end, Fig. 21, of the left-hand channel or head-race. The turbines are of 210 h.p. each, and 14 groups of turbines and pumps have been erected. Four more groups, of somewhat greater power, are expected to be erected within the next five years. The turbines are Jonval pressure turbines, constructed by Messrs. Escher, Wyss, and Co., of Zurich. They have vertical shafts and each turbine drives from a crank two horizontal double acting Girard pumps, placed at right angles.

The head at the turbines varies from 5·5ft., when the river is in flood, to 12·14ft. when the volume of flow is smallest. With most forms of turbine this would involve a considerable variation of the normal speed, or speed of greatest efficiency. The turbines are skilfully arranged to meet this variation of head. The turbine wheel and its corresponding system of guide passages is arranged in three concentric rings. When the fall is great and the quantity of water used is smallest, the outer ring only is open, and the water acts at a large radius. As the fall diminishes, the second ring is opened, and the mean radius, at which the water acts, is smaller. In the lowest condition of the fall, when most water must be used all three rings are open, and the mean radius at which the water acts is smaller still. The number of rotations of the turbine depends entirely on the velocity due to the head and inversely on the radius at which the water enters. Hence, as the radius diminishes as the head diminishes, a fairly constant speed of rotation is obtained. The adjustment is such that, with the highest fall, the normal speed is 27 revolutions per minute, and with the lowest fall, 24 revolutions per minute, a variation not practically serious in working pumps.

The fixed distributor over the turbine wheel is 13·78ft. in external diameter and 5·74ft. in internal diameter. It is divided into three rings, having 52 guide passages in the outer ring, 48 in the middle ring, and 40 in the inner ring. The external ring has no regulating sluices, regulation being effected, when that ring only is open, by the sluices in the head race. The other rings are arranged so that over one semicircle the orifices open vertically on an annular plane surface, and over the other semicircle they open horizontally on a cylindrical surface. Each ring of passages has two regulating surfaces—one a semicircle annular plate for the orifices opening vertically; one a semi cylinder for the openings which are horizontal. Each sluice can be fully opened without interfering with the openings corresponding to the other. The sluices are worked by gearing. The turbine wheel is of cast iron, in two halves. It has wheel passages corresponding to those in the distributor.

The vertical support of each turbine consists of a fixed wrought-iron pillar, carrying at its top a steel step for the pivot and a steel revolving hollow shaft hanging from the pivot at the top. The pivot is 6in. diameter. A crank at the top of the shaft drives two Girard double-acting pumps placed at right angles from a single crank pin. The Girard pump consists virtually of two plunger pumps placed end to end, the advantage being that the stuffing boxes for the plungers are accessible and there is no internal packing. The two pumps discharge into a single air vessel placed between them. The diameter of the plungers of the low pressure pumps is 1·41ft., that of the high pressure pumps 1·08ft. and 0·85ft. The stroke is 3·61ft., and the mean velocity 188ft. per minute. The valves are ring valves with leather faces. The high pressure pumps supply mains of 20in. diameter, and of 24in. and 16in. in the other. The low-pressure pumps supply two mains of 20in. diameter.

(To be continued.)

* "Utilisation des forces motrices du Rhone et régularisation du lac Leman." Th. Turrettini, Ingenieur Conseiller Administratif delégue aux travaux. Geneva, 1890. This admirably illustrated memoir fully describes the origin, progress, and details of all the works at Geneva.

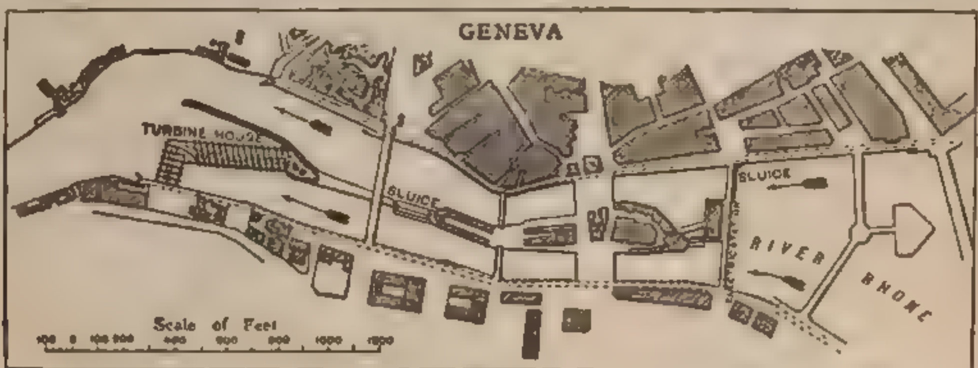

FIG. 21.

LEGAL INTELLIGENCE.

POLLARD v. RUST.

In the Queen's Bench Division on Monday, before Mr. Justice Cave, sitting without a jury, the case of Pollard v. Rust came on for hearing. Mr. Edward Bray was counsel for the plaintiff, and Mr. William Willis represented the defendant.

Mr. Bray said this was an action to recover £1,333. 6s. 8d., two thirds of the sum of £2,000 bonus, which the defendant was alleged to have received from Mr. Charles Langdon Davies, an electrician. The plaintiff's case was that Mr. Rust promised to pay him two thirds of the bonus if he would guarantee the repayment of certain advances which Mr. Rust had made to Mr. Langdon Davies. It was alleged that the £2,000 was received by Mr. Rust, and therefore that plaintiff was entitled to two thirds of that sum. The defence was a denial of plaintiff's allegation, and as a set off that there was a release or discharge from the claim in July, 1887. The plaintiff was a well known barrister, and the defendant, Mr. Arthur Rust, was a merchant, carrying on business at Leicester. Mr. Langdon Davies was interested in certain patents, the object of which was to utilise telegraph wires for the purpose of telephonic work at the same time that they were being used for telegraphy. He had made some arrangements with a gentleman in Belgium with reference to taking over certain patents of that gentleman for the purpose. He wanted money in order to purchase these patents, and to bring out a company. Accordingly he advertised in December, 1883, saying he desired to obtain the use of £10,000—£2,000 at once, £2,000 more later on, and in certain events £6,000 more. Mr. Rust whom Mr. Davies had not known before, wrote to him in relation to the advertisement, and in the correspondence Mr. Rust said he desired to have a guarantee for the repayment of the £2,000 and possibly for the repayment of the further sums. Mr. Pollard, who was a friend of Mr. Langdon-Davies, was mentioned to Mr. Rust. In January, 1884, the parties met at Mr. Pollard's chambers, and Mr. Pollard was willing to guarantee the repayment of £1,500 without any consideration from Mr. Rust, but Mr. Rust wanted something further. He desired, if he advanced the whole £10,000, that Mr. Pollard should be responsible to the extent of £1,500 until the whole £10,000 was repaid. He offered to give Mr. Pollard a portion of his bonus if he would agree to that. Mr. Pollard wrote that in consideration of Rust paying him £750 of his bonus he would do that. Later on Mr. Rust advanced Mr. Langdon Davies another £500, making £2,000 in all, and Mr. Pollard became responsible for the £2,000. Then it turned out that the Belgian patents would not be of sufficient value, but Mr. Langdon Davies had meanwhile made an invention of his own, and a correspondence arose with Mr. Rust with reference to further advances, in carrying out that patent. In

April, 1884, Mr. Pollard expressed his willingness to continue the guarantee of the £2,000, and agreements were drawn up upon which this question depended. The agreement between Langdon Davies and Rust recited that the latter should advance a further £2,000, making £4,000 in all, and keep ready a further sum of £6,000. In case the £10,000 was advanced, it was provided that, in addition to the repayment of that sum, Mr. Rust should have a bonus of £10,000. If a sale should be effected without the £6,000 having been advanced, then Mr Rust was to have £4,000 for keeping the money idle, and if the £6,000 was not advanced, and the company was not formed, the £4 000 was to be repaid with a bonus of £2,000, these sums being paid by instalments. By an agreement between Mr. Rust and Mr Pollard, it was provided that the former should pay to the latter two-thirds of the bonus he received in respect of the first £2,000 advanced to Davies as soon as he received such bonus, Mr. Pollard's guarantee of the £2,000 continuing until all the principal-money had been repaid by Mr. Davies. Later, in July, 1887, an arrangement was come to between Rust and Davies by which the latter sold the former half his patent rights for £5,000, and a discharge of his liabilities to Rust. The result of that, according to the plaintiff's case, was that Rust got his £2 000 bonus, if not a larger sum, and, that being so, Mr Pollard was, under his agreement, entitled to two-thirds of that £2,000.

The **Plaintiff**, in the course of his examination, stated that a company was formed, called the Phonopore Syndicate, to which Rust and Davies were joint vendors of £42,000 in cash and shares. He admitted that he was not entitled to any bonus on the first agreement, but said he was entitled to one on the second. The defendant had never served him with a month's notice that the guarantee was to be continued, as provided for in the contract. He relied on the last contract with him in May, and unless what took place in July between Davies and Rust amounted to the receipt by the latter of a bonus or its abandonment, if good consideration, he had no case.

Mr. Davies also gave evidence in plaintiff's favour.

Mr. Wills, who previously called Mr. Rust, and asked him a few questions as to some of the details of the case, contended in the first place that there was no liability on the part of defendant to the plaintiff at all, as no bonus had been received. Even if there was any liability, it only extended to £666, or two-thirds of £1,000.

The learned **Judge** gave judgment for the plaintiff for £666. 13s. 4d.

THOMPSON v. COWLES SYNDICATE, LIMITED.

In the Queen's Bench Division, on Wednesday, Mr. Thompson, an electrical engineer, of Victoria street, London, sued the Cowles Syndicate, Limited, of Stoke-on-Trent, aluminium manufacturers, to recover £293 odd, for carbon rods supplied. The defendants alleged that the carbons were soft and of inferior quality, and counterclaimed £400 damages. Mr. Moulton, Q.C., and Mr. Tindal Atkinson were for the plaintiff; and Mr. Bousfield, Q.C., and Mr. Bray for defendants.

Mr. Tindal Atkinson, who opened the plaintiff's case, said the real dispute was as to the terms on which the carbon rods were supplied—that is, whether the contract was for the supply of a certain quality in respect to hardness and density or whether they were supplied by sample. The plaintiff's allegation was that the carbons were supplied to sample. The plaintiff was then called, and stated that a number of samples were sent to the defendants to experiment upon, and when they had selected the best for their purpose the carbon rods were sent on to the defendants direct from the manufacturer, M. Berne, of Paris, for whom witness was merely acting as agent in this matter. Witness did not himself see the carbon rods which were delivered, though his information was that they were rods 3ft. long and 3in diameter. In cross-examination, witness said he believed the defendants were the only manufacturers in England who used the electric process for the smelting of aluminium. He denied that an inferior carbon was supplied. A soft carbon was not necessarily inferior to hard carbon; it depended altogether upon the process in which it was used; in some cases the soft carbon would be best. It was in order that the defendants might select the best for their purpose that the samples were sent.

Robert Francis Hayward, formerly manager of the works department of Messrs. Crompton and Co., and who was a year in the employment of the defendants, from 1889 and 1890, said he considered the carbons supplied suitable for the Cowles process.

Mr. Bousfield objected that the Cowles process was not the process used by the defendants now, but Swig's process, which the plaintiff knew very well. The evident was therefore, he submitted, irrelevant.

At this point the further hearing of the case was adjourned till to-day.

COMPANIES' MEETINGS.

CHATHAM ELECTRIC LIGHTING COMPANY, LIMITED.

A meeting of the shareholders in this Company was held at the works, Whittaker street, Chatham, on Wednesday of last week, to consider the proposal of the Directors for the issue of debenture shares to the value of £12,000.

Mr H. Jasper, chairman of the Directors, who presided, said: The chief object of this meeting is to enable me to put before the shareholders the general position of the Company, and the reasons why the Directors deem it necessary that there should be at once an issue of debentures to the extent of £12,000. A considerable sum will be required in the immediate future for the compulsory extension of mains, and for certain necessary extensions of premises; also for the paying off the bank loan and other creditors. We find it will be an easy matter to float the Company's debenture bonds in London if issued at the ordinary rate of interest for such stock. Personally, I think it will be an utter waste of time to issue these debentures at less than £6 per cent., redeemable in 12 years at £105. If they are placed before the public in this way, our substantial works and plant and our present profitable working will form sufficient guarantee and be satisfactory to the most cautious of investors. At this price I shall be willing to take up a considerable portion myself. But I am not anxious in the least degree to do this because it has always been my desire to make this a consumers' company. It was for this reason that I offered the whole of my shares obtained on the contracts of the value of £18 630 at a discount of £33 per cent., not only to the shareholders, but also to the general public. I did this voluntarily, when I found that several of the shareholders had expressed an opinion that my having taken these shares at such a discount was too highly favourable to myself and was very sharp practice, notwithstanding that I had offered the same terms again and again to those whom I thought would have advanced the money absolutely necessary to be found at that time to save our provisional order. Had I then have used my powers for sharp practice I should hold to-day practically all the shares in the Company, seeing that I could at any time have "beared" the market and bought at my own price. This, although often done, would have constituted a proceeding which might be called sharp practice. I threw out this offer more as a challenge to test if any man had the courage of his professed convictions. Not that I at any time desired to part with a single share, nor have I any such desire now, knowing too well the value of the undertaking, but for the fact previously stated that I desired, and still do desire, that this should be a consumers' company. In fact, instead of selling, I have bought out one of the largest shareholders. But to carry out my original object, I am still prepared, for a limited period, to sell a few shares at £25 per cent. premium—but only a few—because I see clearly the great coming advantages of this electric generation. Among these advantages are the treatment of sewage, power, and the fact that the monopoly gives an unlimited dividend—there being no maximum as in the case of gas and water undertakings. I admit that we cannot make such profitable returns as corporations carrying on similar work, because they can with the utmost facility always obtain money at 3 per cent., as may be seen in the case of Grimsby only last week. I should like to point out another advantage there is in corporations carrying on the business of electrical supply: it is that all the ratepayers being partners in the concern would on that account become customers, knowing that they would get a great part of the cost returned in the reduction of their rates. Again adverting to the necessity for the debenture issue, I may say the subscribed capital of the Company is, at the present time, £28,600, of which I hold no less than £25,600, in addition to loans advanced by me to the Company amounting to about £1,400. I am likewise responsible to the bank, in respect of its loan of £3,000, to a further extent of £2,700. I have accepted this responsibility, although our bank, like all the leading banks, will not grant the same privileges as in the case of gas or water stock—viz., advance upon it. But seeing what has taken place at Grimsby and other places, I feel assured that the time is not far distant when bank directors will see it is to their interests to place electric light and power stock on the same footing on gas and water.

A long discussion on matters of detail ensued, **Mr. Leavey** asking, if these debenture shares were issued as explained by the Chairman, what chance would the original shareholders have of ever getting anything out of the Company?

The **Chairman** replied that the Company had now the plant, and this would be complete within a few days, and now they wanted to cover districts with mains which were not already covered. With these debenture shares they would be able to increase their business, and he felt sure that in that event the shareholders would reap an advantage for which they incurred no responsibility whatever.

Mr. Wingent proposed that the amount of debentures at present issued should be sufficient only to cover bank loan (for which he was partly responsible), together with the amount necessary for present extensions of mains; but the Chairman then offering to become responsible for the whole loan, Mr. Wingent ultimately proposed that the meeting sanction the issue of £12,000 in debenture shares on the best terms that could be got, but only £4,000 was to be taken up before another meeting of the shareholders was called.

Mr. Leavey seconded, and the Directors having accepted the motion, it was carried unanimously.

West India and Panama Telegraph Company.—The report of this Company for the half-year ended June 30 states that the amount to credit of revenue is £46 687, against £44,148, the expenses amounting to £24,794, against £28,589. The balance, with £1 430 brought forward, makes a total of £23,323. Of this sum the directors have placed £3,000 to reserve, leaving an available balance of £20,323, out of which it is proposed to pay a dividend on the first preference shares of 6s., one on the second preference shares of 6s., and one on the ordinary shares of 1s. per share, tax free, £4,137 being carried over. The traffic receipts for the two weeks ended October 31 were £120 more than for the corresponding period.

BUSINESS NOTES.

Anglesey. – A telegraph office has been opened at Moelfre, Anglesey.

Bournemouth. – The Corporation intend to apply for a provisional order.

Penrith. – The Board of Health intend to promote a provisional order for electric lighting.

Great Northern Telegraph Company. – The receipts for the month of October amounted to £23,200.

Portsea. – The Board of Guardians intend to have their offices in St. Michael's-road lighted electrically.

Tunbridge Wells. – The Corporation have decided to spend £13,000 in introducing electric light in the chief streets.

Dewsbury. – Tenders are invited by the Corporation by 17th inst. for work in the erection of an electric light station.

Lynton. – Mr. Benn notifies that he is applying for a provisional order in connection with the existing electric lighting works.

Norwich. – The authorities propose to light by electricity the reading room of the Norfolk and Norwich Library at a cost of £100.

Cuba Submarine Telegraph Company. – The receipts for the month of October were £539 less than for the corresponding period.

Direct Spanish Telegraph Company. – The receipts for the month of October were £186 less than for the corresponding period.

Moss Side. – The Collier Marr Telephone and Electrical Manufacturing Company, Limited, of Manchester, have applied for a license for the supply of electrical energy.

Ealing. – A Local Government Board enquiry has been held in regard to the application by the Urban Authority for permission to borrow £25,000 for electric lighting purposes.

East Ham. – The Local Board have constructed an infectious diseases hospital at the sewage works, and have lighted it by electricity, the motive power being supplied by the pumps.

Pontardawe. – An application has been sent to the Board of Trade by Messrs. W. Gilbertson and Co., Limited, of Cardiff, for a license to light certain streets in Pontardawe by electricity.

Newcastle. – The City Lighting Committee of the Corporation have decided that an electric light of 1,500 c.p. shall be placed at the top of Pilgrim-street and another lamp in Newgate street.

Stafford. – The tender of Messrs. Rooper and Tozer for providing and fixing electric light conductors in the new County Council buildings – viz., £460 – has been accepted, this being the lowest offer.

Clay Cross. – At a meeting last week of the Local Board, Mr. Foster raised the question again of the want of more street lamps, and it was mentioned by several members that it was advisable to introduce the electric light.

Redditch. – A deputation of the Local Board, consisting of Messrs. T. W. Baylis, W. Woodfield, W. Gibbs, and T. Evans, has been appointed to visit Rugby, and report upon the system of electric lighting adopted there.

Chiswick. – A letter was read from Mr. Stuart at a meeting of the Local Board last week, as to the maintenance of the electric fire alarms, in which he complained of his cheque being kept back. Instructions were given for the amount to be paid.

Shiplighting. – On Saturday the s.s. "Chickahominy" went on her trial trip off the Hartlepool coast. The vessel is fitted throughout with a complete arrangement of electric lighting, supplied by Messrs. Clarke, Chapman, and Co., of Gateshead.

Blyth. – Councillor Humphreys called attention, at a meeting of the Council last week, to the prompt action of the town clerk in connection with the failure of Mr. J. T. Chappell to execute the work for the extension of the Corporation electricity generating station.

Peterborough. – The following streets have been scheduled in the proposed electric lighting provisional order: Bridge-street, Narrow street, Market place, Long-causeway, Midgate, Westgate from Long causeway to Boroughbury, Church-street and part of Cowgate.

Oystermouth. – The Oystermouth Local Board of Health have requested their engineer, Mr. John Stansfield Brun, C.E., of Mumbles, to prepare and submit to them, at his earliest convenience, a report upon the installation of the district with the electric light.

Western and Brazilian Telegraph Company. – For the six months ended June last the accounts show an available balance, after providing for debenture interest, of £19,679. From this sum £12,000 is to be placed to the reserve fund, leaving £7,679 to be carried forward.

City and South London Railway Company. – The receipts for the week ending November 5 were £871, against £891 for the same period last year, or a decrease of £20. The total receipts for the second half year of 1893 show an increase of £237 over those for the corresponding period of 1892.

Douglas and Laxey Electric Tramway. – Tenders are invited for the extension to Laxey of the existing line from Douglas to Groudle Glen. The work comprises a roadway, and the laying of two lines of 3ft. gauge. Further particulars will be given in *the Contract Journal* next Wednesday.

Blackburn. – The temporary station will be completed in February. The plant will comprise four dynamos, two of 120 kilowatts and two of 45 kilowatts, two batteries of accumulators, each of 60 cells, capable of supplying 300 amperes for $3\frac{1}{2}$ hours. It is intended to charge $6\frac{1}{2}$d. per unit for current.

Brush Company's Shares. – In their November report Messrs. Stanley Geo. Pittield and Co., 4, St. Mary axe, E.C., state that both the ordinary and preference shares of this Company remain very hard at $2\frac{7}{8}$ $3\frac{1}{8}$ and $2\frac{1}{8}$ $2\frac{3}{8}$ respectively, that they have repeatedly advised their purchase, and that they see no reason to alter their opinion.

Belfast. – The report of the Gas Committee of the Corporation presented last week mentioned that the committee had received from Prof. Kennedy several of the principal specifications for the electric lighting plant, and that when the remainder came to hand they proposed to advertise for contractors to tender for the supply of what is required.

Llanelly. – The members of the Local Board, accompanied by the town clerk (Mr. John Jenkins) and the surveyor (Mr. Watkeys), journeyed the other day to Pontypool for the purpose of inspecting the lighting of Pontypool by electricity, and eventually to consider the advisability of introducing the same method of public lighting in Llanelly.

Mine Lighting. – The inauguration of the electric light at Stanton Pit has just taken place. The work has been carried out by Messrs. Verity and Sons, of Birmingham and London. The whole of the screens and loading belts are lighted. This is the first work under the direction of their new agent, Mr. Henry Lee, High street, Burton.

New Cable Offices. – The Eastern Telegraph Company, Limited, have opened a branch telegraph office in the Foreign Auction Hall, Covent Garden Market, for the exchange of telegrams with Spain and the Azores and the company's general system of submarine telegraphs. The Direct Spanish Telegraph Company have opened a branch in the same building.

Dewsbury. – It is intended to instal the electric light at the Self Help Stores. Arrangements are already well in hand for lighting the central premises by electricity. Negotiations are being made with one or two companies with a view to a speedy adoption of the new light, and the installation, it is expected, will be put in during the next few weeks.

Sale of Plant. – On Friday, the 17th inst., the stock and plant of an electrical engineer, comprising handsome electroliers, Gramme and other dynamos, screw cutting and other lathes, fly presses, vices, and other tools, launch and model engines, and miscellaneous electric and gas fittings, etc., will be sold by Mr. J. C. Stevens at 38, King street, Covent Garden.

Tenders for Lampposts. – The Waterhouse Electrical Manufacturing Company, Limited, of 33, Old Broad street, E.C., invite tenders for the supply of electric arc lampposts. Specifications and forms of tender may be obtained on application to the secretary of the company on payment of £2 2s., which sum will be returned on receipt of a *bona fide*, not later than Saturday, 18th November.

Whitehaven. – The Electric Lighting Committee of the Whitehaven Trustees have recommended that the tender of the Asby Colliery Company for the supply of coal to the electric lighting station for six months, being the lowest, be accepted, and that the tender of Mr. R. S. Cousins for entrance gates and posts to be erected at the electric lighting station, being the lowest, should also be accepted.

Tenders Wanted for Plant. – Tenders are invited for the whole of the plant of the Halifax Mutual Electric Light and Power Company, Limited (in liquidation), as a going concern, and consisting of engines, dynamos, switchboards, overhead cables, arc lamps, etc., for an output of 90 kilowatts. The plant can be seen by appointment any evening. Tenders to purchase to be delivered to Mr. William D. Taylor, Town Hall-buildings, Halifax, on or before Wednesday, the 15th inst.

City of Winchester. – At the last meeting of the Town Council a resolution was adopted confirming the award of Mr. Morgan Williams in the matter of the premium recently offered by the Corporation for the most suitable scheme for the lighting of the city. As the result of his exhaustive report on the whole of the schemes, the premium was awarded to the one submitted by the Brush Electrical Engineering Company, the estimated cost being £25,000. The town is at present lighted by oil lamps.

Central American Public Works Company, Limited. – This Company has been registered with a capital of £100,000 in £10 shares. The object is to acquire any real or personal property, and any concessions, rights, or claims in, or to be exercised in, Central America, to construct, maintain, and generally turn to account rail and tramways, piers, bridges, ferries, canals, roads, telegraphs, telephones, also, as builders and contractors, engineers, land agents, etc. The first signatories are: A. W. Higgs, G. S. Bonney, A. H. Downes, H. Robbins, A. W. King, G. G. Nicholson, and A. C. Taylor.

Wrexham. – The town clerk mentioned at a meeting of the Council last week that he had forwarded the resolution as to the purchase of the provisional order of the electric light company, and that he had received a letter from Messrs. Lewis and Son that the matter would be laid before the Board. The Town Clerk said there was an offer from the National Telephone Company to the Corporation to provide a connection with the company's exchange in the Wrexham district for one year, free of all cost, to facilitate communication with the fire-engine station. Mr. Benson moved that the offer be accepted, and the resolution was carried.

Tenders for Bolton.—The Gas and Lighting Committee of the Corporation invite by the 18th inst., tenders for the supply and erection of switchboards, accumulators, connections, etc. Specifications, plans, and forms of tender may be obtained on application to Mr J. H. Rider, M.I.E.E., borough electrical engineer, Town Hall, Bolton, on payment of £1. 1s., which sum will returned on receipt of a *bonâ fide* tender. Sealed tenders, upon the prescribed form, endorsed "Switchboards," must be addressed to Mr Alderman Miles, chairman of the committee, at the Gas Offices, by 18th inst.

Tenders for Newport (Mon.)—The Corporation invite, by the 20th inst., tenders for the supply and erection of steam boilers, feed water heaters, economiser, pumps, mechanical stokers, forced draught apparatus, steam exhaust, and water pipes, condenser, tanks, steam-engines, driving ropes, oil filter, alternators for incandescent lighting, dynamos for arc lighting, switchboards, instruments, arc lamps and lampposts, cables, culverts, surface boxes, junction boxes, converters, converter boxes, converter cases, switches, fuses, meters; also day load plant, to consist of semi-portable engine, alternator and exciter and switchboard, etc. Further particulars were given in our last issue.

Tenders for Sunderland.—The Corporation invite tenders by the 17th inst. for carrying out the work comprised in any or all of the following contracts: (1) Lancashire boilers. (2) High speed compound engines, dynamos, pumps, steam and other pipes, etc. (3) Motor alternators, switchboard, etc. (4) Main switchboard, instruments, and connections. (5) Batteries. (6) Insulated cables, etc. (7) Roadwork (*a*) construction of culverts, laying of cast iron pipes and casings, and building service boxes; (*b*) supply of cast iron pipes, casings, and service box frames and covers; (*c*) supply of stoneware casings and insulators. (8) Copper strip. (9) Gun metal grip boxes. Further particulars were given in our last issue.

The Empire Palace, Bristol.—Messrs. Vaughan and Brown, of London, E.C., have just installed the electric light throughout this building. They have made and fixed massive egg shaped lanterns in brass and glass for the main auditorium ceiling, elegant three arm brackets in ornamental polished brass and coloured glass round the gallery and balcony fronts, also massive electroliers and standards in the stalls, balcony bars, and front entrances. This firm have also installed gas fittings throughout the building, and have fixed in the main ceiling, with ventilating shafts, one of their large patent sun burners. They have carried out the whole of the work in four weeks, under the supervision of the architects, Messrs. Wylson and Long, of London.

Charging an Electric Launch.—An action brought by the General Electric Power and Traction Company Limited, against Mr. Sargeant was heard in the City of London Court on Tuesday. The plaintiffs, of Queen street chambers, claimed £2 against the defendant, Mr W. S. Sargeant, of Twickenham, for charging an electric launch to his alleged order. The plaintiffs' case was that they charged the defendants' launch "Florentia" with electricity to the order of the defendant's servants. The defendant said that he never gave the plaintiffs any order to charge the launch. The defendant was called as a witness for the plaintiff, and he then stated that he had given his servants no authority to give an order. He gave all orders on a printed form. Judgment was given for the defendant, with costs.

Dublin.—An enquiry has been held with reference to an application by the Corporation for a loan of £21,400 for the purpose of extending the electric lighting of the city, and to meet the increased demand from private consumers. Mr Harty alluded to the fact that the private lighting plant was now equal to 5,000 16 c.p. lamps, the number of lamps being 6,500. Stephen's green, Dawson street, Nassau street, Merrion square North, Leinster street, Clare street, part of Merrion square West, Capel street, Mary's lane and a number of other streets are included in the scheme. Mr Robinson, chairman of the committee, stated that the works already erected had proved such a success that the additional outlay would amply recoup them, as a greater number of consumers would be supplied.

Hull.—Two 750 ampere "O.E." meters have been ordered from the maker (Mr. Joseph Edmundson, Albert Electrical Works, Bradford) for registering the total output of the Hull electric lighting station. They are to be coupled to the two outside conductors of the three wire system. An effort is being made to induce the North Eastern Railway Company, as owners of the docks, to take up the question of lighting the docks with the electric light. It is believed that Messrs. Wilson and Co. will be asked to co-operate with the Corporation in bringing about this much desired improvement. The suggestion is that the Corporation should lay down mains with the view of illuminating the quays, sheds, etc., an operation presenting no difficulty, seeing that the central station is situated close to the dockside. The result of the experiment made by the Corporation in introducing the electric light into the town has so far proved a gratifying success, so much so that a reduction in the price to consumers on an early date is confidently expected.

Glasgow.—The minutes of the Gas and Electric Lighting Committee presented at a meeting of the Town Council a few days ago, stated that at a meeting on October 11, Mr. Arnot, the electrical engineer, had submitted the statement of cost which he had been instructed to prepare. The joint sub committees having considered the statement, were unanimously of opinion that, in the whole circumstances, it will be more convenient and expedient to make arrangements for charging the accumulators required for lighting the cars at one or more of the car depôts now being erected by the Corporation instead of getting this done at the existing central electric lighting station in Waterloo street. The minute was approved. At a meeting of the sub committee on galleries on October 20, a verbal report was made by the curator of the galleries as to the cost of lighting the Corporation Galleries by gas, and the report by Mr Arnot as to the cost of lighting them by the electric light having been reconsidered, it was resolved to recommend that electricity should be adopted throughout the galleries, and that the Crompton lamp should be used. The minutes were approved.

Mill Lighting.—The Rock Mill, Waterloo, has been lighted throughout by electricity by Messrs. J. H. Holmes and Co., of Newcastle on Tyne. The installation consists of two dynamos, the larger of which is capable of supplying the whole of the light in the mill; the other is a pilot dynamo for 150 lights for use when the main engine is stopped. The output of the large dynamo is equivalent to lighting 770 lamps. It is driven by belt from a countershaft driven by the mill engine. The pilot dynamo is driven by ropes from the flywheel of a special engine erected by Messrs. Holmes, running at a speed of 175 revolutions per minute. The lamps, which are all of 16 c.p., are provided, in the spinning and carding rooms, etc., with wide, shallow reflectors, painted white, which distribute the light thoroughly without casting a shadow on the cotton. In the staircase and engine room specially strongly guarded fittings are used. The work has been carried out under the superintendence of Mr. Broadbent. An installation comprising 300 lamps has just been put up by Messrs. Bennett and Druce of Preston, in the cotton mill of Mr J. Humber, Preston. The same firm are also equipping Messrs. Hartley Bros.' mills at Preston.

Wolverhampton.—The annual reports of the various committees of the Town Council were presented at the meeting of the Council yesterday. The Finance Committee reported that it would be necessary at an early date to issue Corporation stock or debentures to meet an account for permanent works, together with the amounts required for works of drainage, electric lighting, paving of streets and footpaths, East end Park, refuse destructor, and other general works of a capital nature which are intended to be carried out during the next few years. The question of providing the electric light for the borough was dealt with by the Lighting Committee, and after referring to the appointment of Mr. F. H. Lewis as electrical engineer and architect for the building of the central station, the report states that plans and specifications are being prepared and the engineer is negotiating with the Electric Construction Company, with a view of obtaining a modified tender from them for the plant and machinery necessary to supply electricity for 5,000 incandescent lamps and 40 arc lamps for street-lighting, also with Mr John Thompson for boilers, and Messrs. Calender and Co. for the laying of cables, etc. The architect is also preparing plans for the buildings.

Taunton.—A report on improvements and additions to the station has been sent to the Electric Lighting Committee of the Council by Dr. Fleming. The report deals with (1) additions to boiler plant, (2) additions to dynamo plant, (3) small improvements in the station, and especially an alteration of the steam-piping, (4) laying of the mains underground. Dr Fleming says that the two Babcock boilers now in use are in fair condition. Practically the whole boiler power in the station is in use at the time of heaviest load, and there is no other reserve boiler power in case one of the boilers breaks down; nor is there any possibility of extending the lighting without overloading the boilers. He therefore recommends the committee to lay down an additional boiler of 100 h.p., and that this boiler should be devoted to the arc lighting station. He recommends the acceptance of the tenders of Messrs. Davey, Paxman, and Co. for a steel boiler at the cost of £385, together with £50 for setting it. It is necessary, he says, to put in at once a small alternator to take the load at times when it is very far below the full capacity of the two present alternators. He also recommends that to drive this machine an engine capable of undertaking about 40 h.p. will be required. Under these conditions he expects to produce a marked economy in the coal. The present Willans and Ruston and Proctor engines require overhauling. He points out that it will be necessary at once to commence putting some of the mains underground. He proposes to get rid of the small house transformers, or to keep them for the "pioneer" work and to supply the central portion of the town from one common set of transformers, to be placed in sub stations. From these sub station transformers, underground mains will proceed to the customers.

Swansea.—For some years there has been a good deal of talk about the necessity and the advisability of lighting the main public streets by electricity instead of gas, and of supplying such of the business and residential premises as fall within the central area with this illuminant. During the last two months applications have been made to the Swansea Corporation by several electric light companies who have given notice of their intention to apply to the Board of Trade for a provisional order to enable them to light Swansea with electricity. In 1889, in the Corporation Act of that year, the Swansea municipality obtained an order from the Board of Trade enabling the Corporation to supply electricity for the lighting of the public streets, and for the supply of ordinary consumers within a certain area called the compulsory area, within which limits experiments might be tried, after which, if found successful, it might be extended to a wider region of the borough. Up to the present the Corporation have taken no steps to use their powers for the electric lighting of the borough. But the time is come, says a local paper, when the Corporation must arrive at a decision one way or another. Last week a meeting of the Electric Lighting Committee of the Corporation was held, when it seemed to be the unanimous opinion that it would be a fatal mistake for the

Corporation to allow their electric lighting powers to pass from them into the hands of any private company. The Board of Trade is to be communicated to the effect that no such powers should be granted to any private company until the Corporation have taken steps, as they will at once do, to clear up the matter and arrive at a decision whether they should use or give up the powers they now possess.

Metropolitan Electric Supply Company, Limited. — The following circular was issued on Monday to the shareholders by Mr. F. Cunliffe Owen, the secretary to the Company: "In fulfilment of the desire expressed at the last annual general meeting that the shareholders should be informed as to the Company's progress during the present year the Board have pleasure in stating that the increase of business is being satisfactorily maintained. The number of lamps connected to the Company's system, which in November, 1892, amounted to 114,656, and at the date of the general meeting in April last to 131,453, now amounts to 157,356, and additional applications are in hand for the supply of current to 7,557 lamps. The gross revenue for the six months ending June 30, 1893, shows a very satisfactory advance upon that for the corresponding period of 1892, while the working expenses for the same period fully bear out the views which the Board have frequently expressed as to the small additional cost of production as compared with the increased revenue earned. The gross revenue for the quarter ending September 30 shows that the rate of increase over 1892 continues. The patents relating to the manufacture of incandescent lamps expire on the 10th of the present month, and consequently great reductions in the prices of these lamps are of course being made. While it is difficult to foresee all the results that may arise from a change of so much importance to consumers, there can be little doubt that this Company must benefit by anything which tends to cheapen and popularise the use of the electric light. The Board are so satisfied with the present progress of the Company, that they have no doubt they will be in a position to recommend the payment of half yearly dividends in future years."

One Result of the Coal Strike.—Mr. Dewdney, solicitor, appeared at the Southwark Police Court, on Wednesday, on behalf of the City of London Electric Light Company, Limited, to answer a summons taken out by Inspector Grist, representing the St. Saviour's District Board of Works, Southwark, for an infringement of the Smoke Nuisance Abatement Act by allowing black smoke to issue from their premises at Bankside on several days during the month of October. Evidence having been given by the inspector in support of the summons, Mr. Dewdney said the company did not dispute the facts, but wished the magistrate to take into consideration the circumstances under which the cause of complaint had arisen. The fact was that, in consequence of the coal strike, they were unable to obtain a supply of Welsh smokeless coal for which they had contracted, although they had offered 10s. per ton more than the contract price. In consequence of this they tried to keep their works going by burning coke at considerable inconvenience and increased cost, but after a short time the coke supply also failed, but they were left on the horns of this dilemma: either they must stop their works, which it was impossible for them to do without breaking their contract for the electric lighting of the City, or use other coal, which they could not burn without subjecting themselves to the penalties for which they were now sued. He was happy to say, however, that their difficulty was now at an end, and that for the last week or two Welsh coal could again be obtained, and the company hoped to be in a position to give no further cause of complaint. Mr. F. H. Jackson, the company's engineer, was called in support of the foregoing statement, and after hearing his evidence, Mr. Slade said he would adjourn the case for four weeks in order to see, before giving his decision, whether the nuisance had been abated. This case was adjourned accordingly.

Lighting the Beaconsfield Statue.—At the Westminster County Court, on Tuesday, Judge Lumley Smith had before him the case of the Electric Installation Company v. Juliet, which was a claim by the plaintiff firm for out-of-pocket expenses in connection with the hire of lamps, wires, etc., in connection with an order from Madame Juliet, of Albemarle street, for the illumination of the Beaconsfield statue in Parliament-square, on Primrose Day. Mr. Marriott, solicitor, appeared for the plaintiff company; and Madame Norton, defendant's manageress, represented defendant. John G. O'Brien, plaintiffs' manager, said his firm gave an estimate for illuminating the Beaconsfield statue with incandescent lights. Madame Juliet, a florist, of 1a, Albemarle-street, came and said she had an order to do it from the Primrose League. The estimate was £3. 3s. in the end, as defendant said she would see that plaintiffs were mentioned in "all the Press notices." They got the batteries, etc., from the Electrical Storage Company, and had paid £1 7s. 6d. for the hire of them. They went to Parliament-square, but were not allowed to operate on the statue, as they could show the police no authority but defendant's. This, with the men's expenses, was now claimed. Madame Norton said the work was never carried out. Madame Juliet was sent for by Mr. George Lane Fox to do these illuminations. The Grand Ladies' Council of the Primrose League thought it would be a novelty to have the statue illuminated. The contract was never carried out, then why should defendant pay? His Honour: The plaintiffs received an order from you, and would have carried it out. It was not their fault. Madame Norton: We had Mr. George Lane Fox's word they had permission to do whatever they liked with the statue on Primrose Day. Surely, his word was good enough? His Honour: Well, you must get it back from him. I suppose the ladies thought it would be a novelty. Madame Norton: Yes; they all wanted it done—the Countess of Durham and all the others. His Honour said plaintiffs' claim had been made out to the extent of £1 17s. 9d. They must have judgment for that amount, with costs.

Barrow.—At a meeting of the County Council held last week Councillor Smith moved the following resolution, of which he had given notice: "That, in face of the many recognised advantages of electricity over gas as an illuminant, and its rapidly increasing adoption by other towns, the resolution of the Council of April 6, 1891, authorising the provision, at an estimated cost of £3,000, of certain additional plant at the gasworks to meet the increasing consumption of gas, be rescinded, and that the resolution of the Council of the same date, approving the proceedings of the Gas and Water Committee of March 25, 1891, be varied or rescinded so far as such proceedings approve the proceedings of the 'Additions to Gasworks Plant Sub-Committee of March 24, 1891.'" He said that his motion rose out of the motion he made at the last Council meeting. While there was naturally difference of feeling on the question of the electric light for Barrow, most of the members of the Council would agree with him that they should not expend any more money in increasing the capacity of the gasworks. Councillor Bradshaw seconded the motion. Alderman Strongitharm thought Mr. Smith's motion absurd, and if the mover and seconder thought they were going to advance the electric light question by endeavouring to cripple the development of the gasworks, they would find the majority of the Council against them. Other speakers having spoken against the motion, Councillor Smith, in reply, said that one of the principal objections raised against the electric lighting scheme had been that they had sufficient capacity at the gasworks, but now the argument had gone to the other side, and was strongly in favour of the electric light. It was quite possible with an expenditure of £4,500 or £5,000 they might get a very great increase in the capacity, but this did not alter the other side of the question at all for if they were not anxious to do it now they would be forced to do it next year whether they liked it or not. The motion, on being put to the meeting, was rejected.

Aberdeen.—The Gas Committee of the Town Council have had applications as to an extension of the electric lighting mains for the supply of private consumers in King street, Market street, and Rubislaw terrace. With regard to Rubislaw-terrace, the committee directed that a reply should be returned to the effect that the committee did not see their way in the meantime to recommend the Council to undertake the cost which would be involved in carrying out the extension required. As regarded Market street, the committee authorised the laying of the main for the distance required, the estimated expense being £75; and, with respect to King-street, remitted the application to the superintendent, with powers. These recommendations have been adopted. The Watching, Lighting, and Fires Committee of the Town Council reported, at a meeting a few days ago, that they had under consideration the question of introducing electricity for street-lighting purposes within a certain area. In this connection they had before them a report from the superintendent of the gasworks and the lighting inspector to the effect that, after consultation with Mr. Murray, electrical engineer to the Corporation, in their opinion at least nine lamps of about 2,000 c.p. would be required to light Castle street and Union street (as far as Union Bridge), and one lamp to light St. Nicholas street, and to which reference was made in our last issue. The average distance between the lamps would be about 77 yards. The cost of the scheme, including pillars, lamps, and erection, would be about £252 10s., and the cost of maintenance and current per lamp about 2½d. per hour. The committee resolved to recommend that nine arc lamps should be erected in Castle street and Union street (as far as Union Bridge), and one lamp in St. Nicholas street at the junction of Correction Wynd, according to the plan submitted, and that the Council should remit to the superintendent of the gasworks and the lighting inspector to take the necessary steps for this purpose. Bailie Lyon, in moving the adoption of the report, said that when the Gas Committee made arrangements for getting the electric light into the central district of the city precautions were taken so that the streets could be lighted without taking up the pavement again, and at the present moment the whole thing was completed for all the streets in the area to be lighted, with only the cost of putting up the lamps. Mr. Sinclair seconded the adoption of the report, which was carried.

Trades and Industries Exhibition at Newcastle.—An exhibition of this character was opened at Newcastle on Monday. In the engineering department there is an electric light installation by Messrs. Ernest Scott and Mountain, Limited, of the Close Works, Newcastle. This consists of a 12-unit Tyne compound-wound dynamo, capable of feeding 20 2,000 c.p. arc lamps. The dynamo is driven by an Otto gas engine of 16 h.p. A second dynamo is installed, capable of feeding eight 2,000 c.p. arc lamps to be used at the entrance and in the refreshment-rooms, this being driven by a 4-h.p. gas-engine. The interior of the building is lighted by means of 12 Tyne arc lamps of 2,000 c.p., and three similar lamps are placed outside. Messrs. Ernest Scott and Mountain exhibit, also, a high-speed vertical engine of their own manufacture for electric lighting, a combined engine and dynamo for shiplighting, and a triple-feed pump for working in connection with auxiliary condensers and feed-heaters, and specimens of brass castings. A complete electric light installation is shown by Messrs. Rowland, Barnett, and Co., of Newcastle. It consists of a dynamo driven by a 12 h.p. nominal Stockport gas-engine. The dynamo is capable of giving an output of 100 amperes at an E.M.F. of 65 volts when running at from 400

to 450 revolutions per minute. It energises six arc lamps, varying in power from 500 to 3,000 candles, and numerous incandescent lamps, arranged on a board showing the various fittings are on view. Messrs. Rosling and Matthews, Bradford, exhibit dynamos and other electrical appliances. Messrs. Furnival and Co., of Reddish, exhibit a ½-h.p. and a 4 h.p. silent gas-engines, and on the adjoining stand is a series of exhibits by Messrs. Tangyes, Limited, of Birmingham. The Otto engine, with Pinkney's patents, is shown in motion. Messrs. J. E. H. Andrew and Co., Limited, of Reddish, exhibit through their agents, Messrs. Allen and Robson, a 12 h.p. nominal and 24 h.p. actual Stockport gas-engine, specially fitted for electric lighting, with two extra heavy flywheels and electric light governor, etc. The same agents show, for the Blackman Ventilating Company, Limited, an air fan driven by a gas engine, and a fan and an electric motor combined. The Campbell Gas Engine Company, Limited, Newcastle, have on view two horizontal gas-engines, of 3 h.p. and 8 h.p. nominal, and a 3 h.p. oil engine. Messrs. Peter Burt and Co., of Camlachie, Glasgow, exhibit an Acme patent horizontal gas-engine of 6 h.p. nominal. Gas-engines are also shown by Messrs. Crossley Bros., of Openshaw. A large stand is occupied by Messrs. Thwaites Bros., Limited, Bradford, and contains a "Capell" centrifugal pumping engine, capable of discharging 100,000 gallons, or about 450 tons per hour; a combined pump and electric motor; an improved Roots blower and duplex engine; a 5 cwt. steam hammer; a rapid cupola model, the "Andrew Howatson" patent industrial filter, water softener, patent diurnal water softener, etc. Messrs. Grenfell and Accles, of Birmingham, exhibit a band milling machine, sensitive drill press, tapping machine, and two capstan head lathes on screw machines. The exhibit is designed especially for electrical, cycle, gun, and other concerns where a number of pieces are to be made in duplicate, or where quantities of good screws are required. In connection with this stand are shown examples of self-winding electrical clocks by the Industrial and Mercantile Investment Company, London, through their agents, Messrs. John Mills and Sons, Newcastle and Walker.

Grimsby.—It was mentioned in our last issue that the Town Council had decided to have an interview with Mr. Hammond on the subject of electric lighting. That interview has now taken place, the following being an abstract. The Mayor, in introducing Mr. Hammond, reminded the meeting that having resolved to apply for a provisional order in respect of electric lighting, it was necessary to have some information on the subject. He met Mr. Hammond a little while ago, and that gentleman very kindly offered to come down to give any information which the Council desired. Mr. Hammond first referred to the great superiority of electricity over gas as an illuminant, and then to electrical science and engineering from the early days down to the present. Having described Faraday's methods, he described in detail a central electric station erected on modern lines, advocating steam power in preference to gas as an agent for working the machinery. He also advocated the cutting up of the power in order to keep it in proportion to the amount of electricity required at various periods, and so economise the motive power and at the same time be able to guarantee a constant supply of electricity. In other words, the central supply should not be dependent upon one large engine, which would have to be kept going when only a very small amount of light was wanted, but upon a number of smaller ones which could be brought into use or not as occasion required. Coming to the capital outlay, he said he had endeavoured, by going rather closely into the engineering portion of the subject, to show that it was a very simple thing, that when the plant was properly laid there was no reason why the light should not be supplied without fluctuation from one year to another, and that money invested in electricity works was not invested in a new or unsound thing. Electric lighting undertakers, as they were called, were compelled to file their accounts in a form drawn up by the Board of Trade, and they had to distinguish between their expenditure in coal, wages, works, repairs, maintenance, directors' expenses in case of companies and management expenses in connection with corporations, and not only so, but they must supply the Board of Trade with the number of units turned out at their works, so that it was possible to discover exactly what was done in every electric lighting works. A Board of Trade unit was about 1,000 watts for an hour, equalling 30 lamps of between 8 c.p. and 10 c.p. burning for one hour, or one lamp for 30 hours. In St. James's, London, the Board of Trade unit was produced at 2½d., though their parliamentary powers enabled them to charge 7d. At Bradford, where the works belonged to the Corporation, the cost of production was 2d. per unit, and they only charged 5d. per unit—though they could charge 8d.—and the margin between 2d. and 5d. represented the amount which could be annually set aside for a sinking fund to wipe off the cost of the work. A number of other places were referred to, where margins of 3d., 3½d., 4d., 5d., 6½d., 7d., and 8d. per cent. existed between the cost of production and the price of supply. Thus, where a corporation was in a position to borrow money at 3 per cent., the figures quoted enabled them to do so and to provide a good sinking fund. In the earlier days of electricity the work had been almost wholly done by companies, but it was now being done by corporations, which was owing to the more advantageous conditions brought about by the amended Act of 1888. At the present time there was invested in the electrical industry some four and a half millions—a very surprising figure considering the waste of money in the early days. Of the four and a half millions invested, four millions had been subscribed by companies and only half a million by corporations. There were, however, certain electrical works in course of construction representing £845,000, of which £79,000 was subscribed by companies and £766,000 by corporations. In addition to this there were works actually decided upon representing £820,000, of which £25,000 was in respect of companies and £795,000 in respect of local authorities. These figures showed a total of 6¼ millions invested in electrical works, of which four millions were invested by companies, whilst the amount invested by local authorities had crept from £500,000 to over two millions. He went on to show that specifications could now be got out without waste of money, mentioning that in a recent case, where he prepared the estimates for works costing £25,000, there were only £58 for extras, part of which was for things not really necessary to the scheme. He pointed out there was no defined limit to the uses of electricity; there was no knowing what that mighty force might yet be used for, and in placing down plant the Corporation could, under proper advice, place itself in a position to supply anything which might be wanted. Mr. Connell asked whether Mr. Hammond's experience proved electricity to be suitable for exterior lighting? Mr. Hammond expressed himself thoroughly in favour of the arc lamp. It brought business to a place, and in some instances reduced the expenses of the Watch Committee. Where arc lighting had been properly started from the central station it had never, to his knowledge, been given up. In answer to other queries, he remarked that as time went on there was every possibility of the cost of production being reduced, as it had been in the past. The best thanks of the Council were given to Mr. Hammond, who arranged to give a public lecture on the subject.

Kendal.—At a meeting last week of the Town Council and Urban Sanitary Authority, Councillor Hargreaves moved the following resolution: "That a committee be appointed to consider the expediency of applying, and the steps necessary for the Corporation to apply, for a provisional order to put in force the Acts relating to electric lighting within the borough, and to report." In doing so, he said that resolution required their serious consideration. It was not now necessary to go to the expense of a private Act, as in the case of gas. All that was required was to get a Local Government order at little or no expense, and then there was no difficulty in obtaining money to put in installations. As to the cost of the electric light, he had made enquiries of several high-class firms, and found that the Brush Company, for which Mr. Bevan Braithwaite, son of an old townsman, was agent, would be as reliable as any. In the first estimate he got from them he calculated for street-lighting 300 lamps of 16 c.p. and 32 c.p. That would give a much better light than their present system of gas. He also calculated for 1,500 lamps of 16 c.p. for private lighting. He thought on further consideration, that that installation was too small, as 1,500 lamps for private lighting would only allow for 150 houses and shops with 10 lights each, whereas he found from careful enquiry that many would take the electric light in hotels, clubs, shops, and houses requiring from 20 to 50 lights each. Therefore he asked for a revised estimate providing for 270 street lamps of 16 c.p. and 32 c.p., 30 arc lamps of 2,000 c.p., and 4,000 private lights, which would allow for, say, 200 shops, houses, hotels, etc., with an average of 20 lights each, and these revised figures he had got, and would read the report in full. The following was the report from the Brush Electrical Engineering Company: "(a) The cost of working an electricity supply station capable of dealing with fully 4,000 lamps of 16 c.p. burning at one time installed in private premises including all charges such as fuel, oil and sundry stores, attendance and supervision, repairs and depreciation of buildings, machinery and some mains, and additional municipal office expenses. (b) The extra cost of maintaining 270 incandescence street lamps, of which 170 are assumed to be of 32 c.p. each and the balance of 16 c.p. each; also 30 arc lamps of 2,000 nominal candle-power (say 1,000 actual). In our previous estimate we assumed a 'load factor' of 15deg., but in this case, and in order to be well on the safe side, we have assumed only 10deg.—that is to say, the probable earnings of such a plant is estimated as the equivalent of the running plant (neglecting spare in plant) fully loaded for only 876 hours out of the total 8,760 hours per annum. It will be obvious to you that any increased sale of current beyond this assumption will reduce the cost per unit, as many of the charges making up the total cost would be increased by trifling amounts, if at all, such as attendance, supervision, repairs, and depreciation on plant, etc. The total cost on the above basis is, however, only 3d. per unit. In this connection we may be allowed to point out that the efficiency of the various items of plant, such as boilers, engines, dynamos, and transformers, has a most important bearing on the total cost, and in view of the fact that by the very nature of the load on an electric light station the plant is working for a very large proportion of its time lightly loaded, the 'constant' or 'light load' losses must be reduced to a minimum to ensure the best all the year round result. Many local considerations affect the choice of system, but we are in an exceptionally favourable position to tender on any of the alternative methods—high or low tension, direct or alternating current—as we are manufacturers of all these types of plant. We enclose a list of towns which have established—or are about to establish—an electric light station. The large proportion which have, after investigation, adopted the alternate-current transformer system is significant when it is borne in mind that its introduction is of such recent date compared with its rival, the direct-current system. We may, therefore, assume for the moment that it would best meet the Kendal conditions. This being the case we have only to refer you to the list to establish our fitness to undertake a complete electrical equipment for your Corporation, inasmuch as we have had more experience in this direction than all our competitors in this country combined, and as regards efficiency of plant, the fact that the two companies making the lowest charge to consumers in Great Britain—viz., Newcastle-upon-Tyne Electric

Supply Company 4·05d. net, and Chatham and Rochester E.S. Company 4½d net—are both using our plant speaks for itself. Having standardised the various items of our system upon the results of our large experience, you may have every confidence in placing this important work in our hands, and by adopting such standards in their entirety you would both minimise the first out lay and leave with us an undivided responsibility for the success of the whole undertaking. From our past experience of installations of similar size we should expect the whole installation referred to in the maintenance estimate to cost you about £21,000, including buildings, spare steam and electric generating plant, the arc and incandescent street lamps, and a complete system of underground mains. The cost to the consumer for the first outlay in 'wiring' his premises depends, of course, upon the character of the premises, but the following prices per lamp may be taken as fairly representing the total cost, including lamps, simple fittings, conductors, switches, cut outs, and accessories: Private residences, per lamp, 26s. to 30s.; shops (in straight rows, etc.), 20s. to 24s.; warehouses and factories, 18s. to 25s." Mr Hargreaves next gave in detail the actual working results of 10 companies. He had not gone into the question of water power because he was under the impression that they had not in this neighbourhood sufficient water power for an electric installation. If anything was done it would be simply as an auxiliary. Alderman T. Wilson moved as an amendment that Mr Hargreaves be recommended to postpone the bringing forward of his resolution until they had concluded their negotiations with the gas and water company. This was seconded and on being put to the meeting 15 voted for deferring the question and seven for the appointment of a committee, the motion being therefore lost. It was then agreed that the thanks of the Corporation be given to Councillor Hargreaves for the information he had laid before the meeting. Councillor Hargreaves moved that they ask the Brush Company to send down an engineer, so that a report could be in their hands by the day appointed for the meeting to deal with the question of the purchase of the gas and water concern. Councillor McKay seconded, and remarked that they would not be doing their duty to the ratepayers of Kendal if they went in for the gas scheme with the figures now before them. It would be simple madness if they bought that concern without getting figures and an estimate of electric lighting after what Mr Hargreaves had put before them to-day. Further discussion ensued, but the motion was rejected.

PROVISIONAL PATENTS, 1893.

October 30.

20458. **An electric switch.** Edward Carstensen de Segundo, 28, Southampton buildings, Chancery-lane, London. (Complete specification.)

20459. **Improvements in suspension devices for electric crown lights and the like.** Eugen Rodantz, 323, High Holborn, London.

20471. **Improvements in incandescent electric lamps.** James Graham Tatters, 24, Southampton-buildings, Chancery-lane, London.

20493. **An improved electric flash light clock.** Herbert Young Dickenson, 56, Gray's inn road, London.

October 31.

20551. **A new or improved switch and cut-out for electroliers.** Henry Birkbeck, 34, Southampton buildings, Chancery-lane, London. (The Universal Pull Socket and Switch Company, United States.)

20557. **Improvements in electrical switches.** Eugen Rodantz, 8 Lord street, Liverpool.

20584. **Improvements in the manufacture of elements for electric or secondary batteries.** Augustus John Marquand and Emanuel Hancock, 24, Southampton-buildings, Chancery lane, London.

November 1.

20625. **Improvements in and connected with carbon electrode connections.** Harry Theodore Barnett, 14, Narcissus road, West Hampstead, London.

20686. **Improvements in electrical condensers.** William Ernest Gray and William Arthur Price, 6, Bream's buildings, Chancery lane, London.

20696. **Improvements in and in connection with electric cables.** George Gatton Melhuish Hardingham, 191, Fleet street, London. (The firm of Felten and Guilleaume, Germany.) (Complete specification.)

November 2.

20723. **Improvements in electric measuring instruments.** Walter Thomas Goolden and Sydney Evershed, 1, Woodfield road, Harrow road, London.

20732. **An electrical or mechanical apparatus in connection with a ship's sounding lead, or for cognate purposes.** William Aldred, 5, Brightside bank, Brightside, Sheffield.

20741. **Improvements in swing or movable joints especially adapted for electric light fittings.** James Aram Lea, James Francis Lea, and Arthur Henry Lea, Pengwoone Works, Chester street, Shrewsbury.

20788. **Improvements in electric stop motions for warping machines.** *Clayton Dean, John Cocker, and Charles Dean, 53, Chancery-lane, London.*

20735. **Improvements in lightning conductors.** Joseph Ball, 4, Corporation street, Manchester. (Complete specification.)

20793. **Improvements in recording instruments for electric telegraphs.** Alexander Muirhead, 124, Chancery-lane, London.

20799. **Improvements in electric incandescent lamps.** Marie Henri Hartogh, 37, Chancery-lane, London. (Complete specification.)

20816. **Improvements in connectors for electric conductors.** Herbert Rudolph Keithley, 45, Southampton-buildings, Chancery-lane, London.

November 3.

20837. **Improvements in electrostatic and other electrical measuring instruments.** William Edward Ayrton and Thomas Mather, The City and Guilds of London Central Institution, Exhibition road, London.

20840. **Electric firedamp indicator.** Albert Ebenezer Schurr, Lyncot, Leigh on Sea, Essex. (J. Cauderay, Switzerland.)

20847. **Improvements in carbon brushes blocks or collectors for electric generators and motors.** William Harding Scott, Gothic Works, King street, Norwich.

20859. **A process by which by combined chemical and electrical action he obtains motive power.** Frederick Gwilym Trehane, Llyndérw, Llanishen near Cardiff.

20883. **Improvements in brackets or supports for insulators for telegraphic telephonic, and other like purposes.** Bullers Limited, and Edward John Chambers, 7, Staple inn, London.

20887. **Improvement in incandescent lamps.** Arthur Stephen Ford and William Barnes, 12, Basinghall street, London. (Complete specification.)

20891. **Improvements in phonographs and telephones.** Philip Arthur Newton, 6, Bream's - buildings, Chancery lane, London. (Alfred Nobel, France.)

20896. **Apparatus for working semaphore signals by means of electric currents.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

November 4.

20915. **Improvements in alternate - current synchronisers.** William Edward Ayrton and Thomas Mather, Central Institution, Exhibition road, London.

20923. **Improvements in the means of charging and discharging primary electric batteries.** Harry Theodore Barnett, 14, Narcissus road, West Hampstead, London.

20966. **Improved incandescent electric lamp.** John Plummer, Colinton, Midlothian.

20975. **Improvements in voltaic batteries.** James Augustus Seymour Gregg, 28, Southampton buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1892.

18066. **Electric meters.** Golby. (Dejardin.)

18966. **Electrolytic decomposition of metals and sulphur.** Siemens Bros and Co., Limited. (Siemens and Halske.) (Second edition.)

21376. **Electrical resistances.** Edmunds.

21377. **Electrical conductors.** Edmunds.

22187. **Lightning arresters.** Belfield. (Westinghouse Electric and Manufacturing Company.)

22473. **Dynamo electric machines.** Brown.

23007. **Galvanic batteries.** Walker and Wilkins.

23054. **Electric induction coils.** Davis.

23902. **Alternate-current motors.** Brown.

1893.

12662. **Electrolysis.** Andreoli.

15681. **Electric accumulators.** Roe and Sutro.

NOTES.

Traction in Italy.—It is proposed to construct an electric tramway between Milan and Corteolona.

Blackpool.—The use of the electric light is enabling the work on the tower to be more rapidly accomplished.

Kingston.—The Surrey County Council buildings at Kingston-on-Thames are lighted by electricity from the municipal station.

Bristol.—The Bristol Carriage and Tramways Company propose to apply for powers to introduce electric traction on their lines.

Recent Solar Discoveries.—A lecture on this subject was delivered by Sir Robert Ball on Monday at the London Institution.

Glasgow.—An explosion, which tore up some part of the pavement, occurred a few days ago in connection with the electric light conduits.

Newcastle.—The North-Eastern Railway Company propose to lay down an electric light installation on the property adjoining the goods station.

Carlisle.—An institute of literature, science, and art, as mentioned in another column, has been opened by the Mayor. The building is lighted by electricity.

Personal.—Mr. W. F. Taylor, consulting electrical engineer, of Boswell Court, Croydon, has been elected to the County Council of the borough of Croydon.

Battersea Town Hall.—The new Town Hall at Battersea, opened on Wednesday, is lighted by gas, the reason being that there is no public supply of electricity available.

Watts the Matter?—An esteemed contemporary, in referring to the lighting of a mill in its last issue, states that "the dynamo was tested for five hours continuously with a load of 55,000 volts"!

Telephony.—The erection of the trunk wire between Dover, Canterbury, Chatham, and Maidstone has been completed. It is expected that communication will be opened up with London by Christmas.

Electrotechnical Progress.—We have received a copy of *Fortschritte der Elektrotechnik*, being the fourth issue of this year. It is issued, under the auspices of Dr. Karl Strecker, by Mr. Julius Springer, of Berlin.

Cost of Electric Lighting.—We have received a copy of a table showing the total cost of electric lighting when using "Robertson" incandescent lamps of 16 c.p., at various efficiences, in watts per candle-power.

The Institution.—At the ordinary meeting on Thursday, the 23rd inst., a discussion will be commenced on the paper read last week by Prof. Forbes on "The Electrical Transmission of Power from Niagara Falls."

Traction at Ipswich.—The service of tramcars was discontinued on Saturday owing to the inability of the company to meet a certain payment to the Town Council. Electric traction does not appear to have been considered.

Electric Launches.—Launches of this type are to be used at Venice. On the 28th ult. a trial trip was made with one of these boats, constructed to carry 28 persons, and capable of being propelled at the rate of about 10 miles an hour.

"A Death Dealer."—Mr. Davis, the New York State executioner, is reported as about to apply for a patent for an electric death-dealing apparatus which he thinks will allow of the carrying out of the electrocution law without any trouble whatever in the future.

"Cassier's Magazine."—The London offices of this magazine have been removed to 5, Chandos-street, Strand. In the October number an account is given of the life and inventions of Edison, and a paper on improvements in cable-making. Besides these, the issue contains other interesting articles.

Submarine Boats.—The new submarine torpedo-boat, "Radatz," has undergone a successful trial on Lake Winnebago. The boat, which is 40ft. in length, is propelled and lighted by electricity. She carried three men, and on the occasion of the trial remained under water an hour under perfect control.

Zanzibar.—The Eastern Telegraph Company announce the laying and opening for traffic of the cable between Zanzibar and the Islands of the Seychelles, being the first section of the cable Zanzibar-Seychelles-Mauritius. The extension of the cable to the Island of Mauritius is expected to be completed by the end of this month.

Dr. Tibbits and Mr. Harness.—We are informed (says the *British Medical Journal*) that Dr. Tibbits, who was the plaintiff in the action of Tibbits *v.* Alabaster and Gatehouse, has been struck off the list of Fellows of the Royal College of Physicians, Edinburgh, for aiding Mr. Harness in selling "electropathic belts" which were declared to be worthless medically.

Omnibus-Lighting.—The prospectus is being issued of the Omnibus and Tramcar Electric Lighting Company, Limited, who will deal with lighting according to Mr. Pitkin's patents. The company will undertake the lighting of private vehicles from similar accumulators, etc., as supplied to the Lord Mayor's carriage—referred to in our last issue—or with the illumination of public carriages as now provided on the London street tramways, the London General Omnibus Company, and private omnibuses.

Birmingham Electric Cars. — The Birmingham Central Tramways Company have, after trying plates of another type for more than 12 months, decided to renew the whole of the battery with plates manufactured by the Electrical Power Storage Company, Limited. We understand that two batteries of the original plates manufactured by the Electric Construction Corporation (the then owners of the E.P.S. patents), and which were supplied more than two years ago, have been regularly working and giving excellent results.

Arbitration.—The Chamber of Arbitration established by the London Chamber of Commerce was considered on Tuesday at a meeting of the latter. Sir Albert Rollit, M.P., in a comprehensive address, remarked that he was in favour of arbitration all along the line whenever it was possible. At the close a resolution was passed approving of the formation of the Chamber of Arbitration, submitting that its machinery provides for rapid, cheap, and effective settlements of business, and recommending traders in the City of London to make use of the Chamber whenever differences arise in regard to the settlement of all points.

The Government and Telephony.—The delay on the part of the Postmaster-General in placing before Parliament his new agreement with the National Telephone Company is said to be exciting general remark in political quarters. The explanation is stated to be that the directors of the company have made some difficulty about assenting to certain provisions in the agreement. A correspondent believes, however, that the friction between the Post Office and the company has now been removed, and it

is thought that when the matter is mentioned in the House to-day, Mr. Arnold Morley will be in a position to make a definite and authoritative statement.

The Lyons Exhibition.—The Exposition Universelle Internationale et Coloniale in 1894 at Lyons, which has the support of the French Government and of the leading chambers of commerce throughout the country, bids fair, we are informed, to become the most important enterprise of its kind ever attempted on the Continent out of Paris, judging from the numerous applications for space which are pouring in from all parts. The Executive Committee has appointed Mr. Brandrethas, of the Anglo-Continental Contract Association, Limited, 52, Queen Victoria-street, E.C., their agent for Great Britain and Ireland, and they will supply those who may desire to exhibit with full information concerning terms and conditions on which spaces will be allotted in the British section.

The "Medical Battery" Company, Limited.—On Wednesday at the Marlborough Police Court, the hearing was resumed of the charges of conspiracy to defraud brought against Mr. C. B. Harness, Mr. J. M. M'Cully, and Mr. C. B. Hollier. After receiving evidence for the prosecution, the hearing of the case was adjourned for a week, the bail in the case of Mr. M'Cully being reduced to two sureties of £100. The application of Mr. Browne for the compulsory winding up of the "Medical Battery" Company, Limited, and which was deferred from last week, was again considered on Wednesday. Mr. Justice Williams ordered the voluntary liquidation to be continued for another week, the key of the minute-book of the company to be produced in the meantime.

Westminster Electric Supply.—In our article on the Westminster central stations, on November 3, dealing with Davies-street station, the curve given was inadvertently entitled "Load Diagram at Eccleston-place"; it should have been "at Davies-street station." With reference to last week's article on cost of generation, Prof. Kennedy wishes us to point out that the "chief engineer" to a company has so much to do with distribution, and also especially with the arrangement of new plant, that it would be incorrect to charge his salary entirely against generating expenses. Strictly speaking, part of his salary is for generating, part for distribution, and a part for capital account. The Westminster Corporation, however, put all to revenue, and charge it to central expenses so as to be fair. The important point is that the expense for chief engineer should be put to "revenue" and not to "capital," as is sometimes done.

"Sunbeam" Lamps.—A price-list of the "Sunbeam" incandescent lamps, which were first introduced in 1887, has now been issued by the Sunbeam Lamp Company, Limited, of Gateshead-upon-Tyne, and of 50, Fenchurch-street, E.C. We are informed that since the manufacture of these lamps was suspended owing to the existence of the master incandescent lamp patent, the company has been reorganised on a new basis, and that a large factory equipped with the latest improvements has been completed. The company is now turning out incandescent lamps of from 8 c.p. up to 2,000 c.p. The high candle-power lamps, which are specially suitable for lighting large areas, are made in two classes—namely, those of high efficiency and those of longer duration. Lamps to run in series are now provided for 5, 6, 8, and 10 ampere circuits, and of various candle powers. The company are making the "Sunbeam" lampholders in two sizes.

The Milan Tramway.—We have already mentioned *in a previous issue that* an electric tramway on the *Thomson-Houston system has* been constructed in Milan, and we now give the following particulars of the line, which has been constructed by the Società Generale Italiana di Elettricità Sistema Edison. The line, which is double, starts from the Piazza del Duomo and ends at the Corso Sempione. The generating plant, which is contained in the central station which supplies the current for the public lighting of the town, comprises two steam engines of 200 h.p., and two Thomson-Houston dynamos giving 200 amperes at 500 volts. There are 10 cars in service, each capable of accommodating 34 passengers. The cars are fitted with electric bells, and lighted at night by five 16-c.p. lamps. Each car is equipped with a 15-h.p. motor, which is capable of working at a higher power if necessary. The line was opened to traffic on the 2nd inst.

Telephonic Communication for Hospitals.—Writing to the *Times*, Mr. Alfred S. Gubb, M.D. (Paris), states that a wave of public opinion has at last overcome the inertia of the authorities and will shortly have been the means of placing the keepers of lighthouses and lightships in telephonic communication with their inland fellows—a simple and by no means costly convenience, which it has taken years to bring about. The success obtained in this direction suggests the possibility of inducing the governing bodies of our large general hospitals of London to avail themselves of the facilities afforded by the telephone for rapid and easy communication with other hospitals. A hospital is not a self-contained, independent, administrative entity, but a segment of the hospital administration of the metropolis, and he states that it is eminently desirable—nay, absolutely necessary—that each segment should be enabled to communicate freely and easily with the remainder.

Manchester and Telephony.—A matter of great importance brought up at a meeting of the Town Council on Wednesday was the reception of the report of the Parliamentary Sub-Committee, and the approval of the same by the committee. This showed what the committee had done in regard to the proposal of the telephone companies to obtain statutory powers for taking wayleaves and underground modes of conveying their wires. From this report it appeared that the Special Committee of the Municipal Corporations' Association came to the conclusion in August that it would be undesirable to grant these powers unless statutory limitations were imposed upon the undertakers, and subsequently had interviews with the Board of Trade and the Post Office authorities. The upshot of these exertions was that the Postmaster-General consented on September 11 to lay before Parliament the proposed agreement with the telephone companies before it was executed.

Electric Light Cables and Wires.—A new price-list of electric light cables and wires (vulcanised and unvulcanised indiarubber) has just been issued by Messrs. W. T. Henley's Telegraph Works Company, Limited, of 27, Martin's-lane, E.C., and North Woolwich. The list, which gives instructions for making joints, contains particulars of electric light wires composed of tinned copper (100 per cent. conductivity), insulated with pure and vulcanised indiarubber, and taped, the whole being vulcanised together and compounded; of similar wires taped or felted, vulcanised, then braided with yarn and compounded; vulcanised electric light cables similarly treated, concentric cables, lead-covered wires and electric light cables; electric light wires insulated with pure indiarubber, braided and compounded, cables insulated with indiarubber and not vulcanised; twin flexible electric light cords, wood casings, jointing materials, etc. It may be mentioned that [illegible] wires and cables referred to are te[illegible] immersion in water at 60deg.

electrification and the minimum insulation resistance is noted on each coil.

Brighton and Rottingdean Electric Railway.—The prospectus is being privately circulated of the Brighton and Rottingdean Seashore Electric Tramroad Company, which has been formed with a capital of £20,000, divided into 2,000 shares of £10 each. The company has been established to construct an electric tramway, together with landing stages, to provide a ready means of communication between Brighton and Rottingdean both for passenger and parcels traffic. The length of the line will be about three miles. It is not expected that more than £12,000 will be needed for building and equipping the line, and in the acquisition of the necessary land. Of the 2,000 shares 232 have been issued fully paid to the promoters in satisfaction of all costs, charges, and expenses of and incident to the preparing for obtaining and passing of the Act, and £4,000 has been subscribed by the directors. The present issue is 1,200 shares, payable £1 on application, £1. 10s. on allotment, two calls of £2. 10s. each, and the remainder as required. The offices of the company (of which Messrs. E. O. Blackley, J. J. Clark, A. J. Rawlinson, and M. Volk are directors) are at 58, Ship-street, Brighton. The directors have every confidence in the success of the undertaking.

Intensities of Lighthouse Lights.—The second meeting of a conference of the General Lighthouse Authorities of the United Kingdom and their engineers, together with representatives of the Admiralty and Board of Trade, has been held at Trinity House. It was decided to publish in the official list of lights the candle-power of each light as determined by the engineers. By this means mariners will be informed of the relative illuminating powers of all the principal lights on the coast. The members of the conference were Sir Sydney Webb, deputy master of the Trinity House, in the chair; Vice-Admiral Sir George Nares, F.R.S., of the Board of Trade; Captain Wharton, R.N., F.R.S., hydrographer to the Admiralty; Sir Robert Ball, F.R.S., scientific adviser to the Irish Lighthouse Board; Captain Burne, elder brother; and Mr. Charles A. Kent, secretary of the Trinity House; Sheriffs D. B. Hope and R. N. Campbell, Northern Lighthouse Commissioners; Messrs. W. Watson and G. B. Thompson, Commissioners of Irish Lights, with Mr. T. Matthews, Mr. D. A. Stevenson, and Mr. W. Douglass, the engineers of the English, Scotch, and Irish Lighthouse Boards respectively. Mr. E. Price Edwards acted as secretary to the conference.

Fire Risks in Electrical Insulation.—In concluding an article on this subject in the *Engineering Magazine*, Mr. F. A. C. Perrine says: "We believe that we may truly say that an installation for the electric lighting of any building may be made perfectly safe as regards fire risks; using the word 'perfectly' in the human sense, for we know nothing connected with either science or our daily lives in which every form of possible accident may be absolutely guarded against. Such a perfect installation we now understand to be one in which the wires have been properly proportioned to carry their normal current without undue heating; where also fuses are placed on all the branches to blow out whenever the current rises dangerously above that normal; and where not only the insulation of the wire is thoroughly waterproof, but where also its supports are of an incombustible waterproof character, and so arranged as to keep the wire [illegible] tact with all combustible materials; and, above [illegible] inspection, cleaning, and testing, the [illegible] in its original character through[illegible] safe, then, good and honest workmanship must be maintained by constant watchfulness, and not by fancied security."

Coating the Hulls of Vessels with Copper.—A method of coating the hulls of vessels with copper electrically has been devised by Mr. Thomas S. Crane, and is being introduced by the Ship Copper Coating Company, of Newark, N.J. The method consists primarily in the use of flexible, shallow, box-shaped baths, open at one side. Each bath contains a copper electrode and the plating solution, the bath being made watertight by suitable flexible packing at the edges. Several of these baths are used in the plating of the vessel when in dry dock or upon the stocks, the cleaning of the hull at any one time being only necessary in the places where the baths are to be applied. The baths, which are made flexible in order to follow the curvature of the vessel, are readily supported against its side, on its bottom, and along its keel and in other difficult situations, by comparatively simple means. The vessel is made the negative pole by connection with an electric generator; the plating-bath furnishes the positive electrode, and the plating of the entire hull is readily accomplished by shifting the baths from the plated to the unplated sections, and slightly overlapping upon the sections already plated so as to form a continuous coating. It has been found that a current rate of 7½ amperes per square foot and a difference of potential of 1½ volts are sufficient to deposit a perfectly uniform, smooth, and adherent coating to the metallic surface of the vessel.

The Allgemeine Elektricitats Gesellschaft.—We have received a copy of the eleventh report of this Company for the year ending June 30 last, and which will be presented at a meeting of the shareholders on the 28th inst. It may be interesting to learn that this Company, the capital of which is £1,000,000, has as general director Mr. E. Rathenau; and on the administrative council, Dr. G. Siemens, of the Deutsche Bank; Mr. Carl Furstenberg, of the Berlin Handels Gesellschaft; and Mr. Arnold von Siemens, of Messrs. Siemens and Halske. The report shows that the net profits for the year 1892-93 amounted to £80,037, as compared with £75,039 in the previous year. The sum of £80,037, added to the profit brought forward from last year, reaches a total of £97,665, out of which a dividend at the rate of 8¼ per cent. is recommended. This absorbs £82,500; the fees of the administrative council, £4,125; fees of the Board, £5,775; allowances to officers and the pension fund, £4,125; and to the benevolent fund, £250, leaving £890 to be carried forward. The Company now have in hand orders to the value of £562,500, as against £512,500 last year, and favourable results are expected for the current year. The report deals fully with the work accomplished by the Company and with the condition of that now being carried out. The Company have constructed since 1891 six electric tramways in Germany, and they have eight additional lines in course of being erected in Germany, Russia, and in Christiania.

Accumulator Traction in New York.—A service of accumulator cars has been in operation on the Second-avenue surface road since last April, the cars being equipped with Waddell-Entz motors and copper-steel alkaline accumulators. The total mileage run to October 15 was 40,000 car miles. The cost for electric power per car mile works out at 9·32 cents, or, say, 4⅔d. The *Electrical Engineer* of New York, in an editorial on the storage battery outlook, remarks that the figure of 9·32 cents, "of course, exceeds that which may be attained with the trolley system, but the cost for the same items of expense when figured on the basis of 18 cars would compare far more favourably with that of the trolley. If in addition we take into

consideration the cost of overhead construction and its maintenance, the high efficiency at which the engines can be operated, and the other advantages accruing from having the entire operating force constantly under the eye of the superintendent, this disparity is still further lessened. The frankness of the Waddell-Entz Company in thus making public figures which could be obtained in no other way is to be most heartily commended, and we sincerely hope that their present successful attempt on the Second-avenue road may be the forerunner of a considerable application of the storage battery to traction work in the United States. It may take some time yet to heal fully the wounds of the past, but with a better understanding of the nature and capabilities of the storage battery, America may yet turn its early storage battery experience to good advantage."

The Electro-Harmonic Society.—The ladies' night will be held next Friday, the 24th inst., in the Banquet-room of the St. James's Hall Restaurant, Regent-street, W., commencing at eight o'clock. The following is the programme: Part I.: Trio, "Ti Prego" (Curschmann), Miss Annie Swinfen, Miss Mary Hay, and Mr. Maldwyn Humphreys; song, "O, Star of Eve" ("Tannhauser"), (Wagner), Mr. Robert Grice; vocal valse, "Il Bacio" (Arditti), Miss Annie Swinfen; pianoforte solo, "Scherzo," B flat minor (Chopin), Mr. Alfred E. Izard; song, "Annabelle Lee" (H. Leslie), Mr. Maldwyn Humphreys; recitation, "Bergliot," with Greig's music (B. Björnsen), Mrs. Turnbull; songs (a) "All Souls' Day" (Edouard Lassen), (b) "The Double Loss" (Meyer-Helmund), Miss Mary Hay; violin duet (unaccompanied) "Serenata" (No. 1) (Viotti), Tempo Giusto—Andante—Andante con Variazioni—Allegretto—Menuetto—Tempo Giusto, MM. T. E. Gatehouse and J. Greebe; humorous sketch, Mr. George Schneider. Part II: Duet, "Flow Gently, Deva" (J. Parry), Messrs. M. Humphreys and R. Grice; song, "I Dream't that I Dwelt" (Balfe), Miss Annie Swinfen; violin solo, "Benedictus" (Dr. A. C. Mackenzie), Mr. T. E. Gatehouse; new song, "Blue-eyed Nancy" (S. Adams), Mr. Robert Grice; original sketch, "Our Waltz" (E. Turnbull), Mrs. Turnbull; new song, "Voices in the Heart" (W. Slaughter), Miss Mary Hay; violin duet, "Double Rondeau" (L. Jansa), MM. T. E. Gatehouse and J. Greebe; song, "The Dream of My Heart" (Bevan), Mr. Maldwyn Humphreys; humorous sketch, Mr. George Schneider.

Thunder and Hail Storms.—At a meeting on Wednesday of the Royal Meteorological Society, Dr. C. Theodore Williams, president, in the chair, Mr. W. Marriott, F.R.Met.Soc., gave an account of the "thunder and hail storms" which occurred over England and the south of Scotland on July 8, 1893. Thunderstorms were very numerous on that day, and in many instances were accompanied by terrific hailstorms and squalls of wind. It was during one of these squalls that a pleasure-boat was capsized off Skegness, 29 persons being drowned. About noon a thunderstorm accompanied by heavy hail and a violent squall of wind passed over Dumfries and along the valley of the Nith. Many of the hailstones measured from 1in. to 1½in. in length. At the same hour a similar storm occurred at Peterborough. From about 2 until 10 p.m. there was a succession of thunderstorms over the north-east of England and south-east of Scotland, and at many places it was reported that the thunderstorms were continuous for nine hours. Two storms were remarkable for the immense hailstones which fell during their prevalence over Harrogate and Richmond in Yorkshire. The hailstones were 4in. and 5in. in circumference, and some as much as 3in. in diameter. Great damage was done by these storms, all windows and glass facing the direction from which the storm came being broken. It is computed that within a radius of five miles of Harrogate not less than 100,000 panes of glass were broken, the extent of the damage being estimated at about £3,000. The thunderstorms in the northern part of the country travelled generally in a north-north-westerly direction, at the rate of about 20 miles an hour. They appear to have taken the path of least resistance, and consequently passed over low ground and along river valleys and the sea coast. Several storms seem to have followed each other along the same track.

Treatment of Cancer by Electricity. In the course of an article in the *Lancet* on "Rodent Cancer and its Treatment by Electricity," Dr. J. Inglis-Parsons, M.R.C.P., states that this disease, better known as rodent ulcer, is one of the forms of malignant disease resembling epithelioma in its minute structure. With regard to treatment, he remarks that two methods have found favour with surgeons—namely, excision by the knife, and destruction by caustics. Electricity, he says, is not only free from the drawbacks incidental to these two methods, but it has other advantages. The electrolytic action prevents any hæmorrhage, so that the operator is able to see exactly how far he has gone, and to avoid any unnecessary destruction of tissue. There is no pain after the electrical application—in fact, for some days after-sensation is quite abolished The amount of destruction can be regulated with the greatest nicety by increasing or diminishing the strength of the current. The cicatrix which follows appears to leave less deformity than when other means have been employed. For an ordinary case one application under an anæsthetic is sufficient, but with a large ulcer two or three may be necessary. Two needles are employed, with a current strength of 200 to 400 milliamperes. The caustic action of both poles is freely used, and the current is constantly alternated with a band commutator. There is no danger in a current of this strength if care is used. There is no shock afterwards, and the patient can even get up the next day in many instances. No rise of temperature takes place if the wound is kept aseptic. The sloughs separate in the course of a week or 10 days, and the ulcer soon heals, leaving a firm cicatrix. Skin grafting is sometimes required. If at any future time a suspicious-looking spot should appear, a short application lasting five or ten minutes will dispose of it. In any case a year or two of immunity can be promised even with a difficult subject.

Electricity in Mining.—Before the Manchester Geological Society, on Tuesday, Mr. W. Saint (president) referred to recent improvements in mining machinery and appliances. He remarked that since the first introduction of electricity as a motive power in mines, improvements had been introduced with a view to prevent the possibility of ignition of explosive mixtures of fire-damp and air, either by sparks from the commutator or an accidental severance of the cables; but even with these precautions it was for engineers to consider whether the cables and motors could be safely placed in position where a naked light could not be used. Its introduction had passed the experimental stage, and there was every possibility that its application would be largely extended. Coal-cutting machines had not been adopted on a large scale in this country, probably owing to the fact that, as a rule, they were only applicable to long-wall working, in which the coal was not usually difficult to get by manual labour. This, however, did not apply to the Stanley heading machine, which had been designed for driving narrow roads. It consisted of a vertical disc, carrying longitudinal cutter bars, which were revolved against the face of the heading by a pair of small vertical engines and powerful gearing worked by compressed air. The bars made an annular

cutting, leaving a central core of coal, which was broken up by wedging and removed by hand. The length of the cut was about 24in., and under favourable conditions the speed of driving was 3ft. to 4ft. per hour. The machine had been thoroughly tested during the past few years, and was a practical success, its chief merit being the increased proportion of large coal obtained from narrow roads and the saving of time in executing a given quantity of work. As to lighting, the president said that nearly all the principal collieries were now provided with installations of the electric light for illuminating the surface works and the main roads, etc., near the bottom of the winding shafts. It compared favourably with coal gas as regards illumination, cost, and immunity from risks by fire.

Fusion and Volatilisation of Metals and Oxides in the Electric Arc.—In the *Compte Rendus* M. Moissan deals with this subject. He states that in order to condense and collect the substances that sublime, a copper U-tube, through which a rapid current of cold water is continually passing, is introduced into the electric furnace immediately above the crucible containing the substance under investigation. Asbestos cardboard placed above the opening through which the U-tube is introduced serves also to condense some of the vapour. When magnesium pyrophosphate is submitted for five minutes to the action of the arc formed by a current of 300 amperes and 65 volts, a sublimate of magnesium oxide and ordinary phosphorous is obtained. Asbestos, with 300 amperes and 75 volts, almost completely volatilises in a few minutes, and leaves only a small residue of the fused silicate, together with a small globule of magnesium silicide. Copper, with 350 amperes and 70 volts, volatilises rapidly, and condenses in globules. The vapour forms cupric oxide in contact with air. Silver readily enters into ebullition, and distils more easily than zirconia or silica. It condenses in fused globules, a grey, amorphous powder, and arborescent fragments. Platinum melts almost immediately, and very soon begins to volatilise, condensing in brilliant globules and also in the form of a powder. Aluminium, with 250 amperes and 70 volts, likewise volatilises, and condenses in small spherules. Tin, with 380 amperes and 80 volts, volatilises readily, and condenses in small globules and in fibrous masses. Gold, with 360 amperes and 70 volts, volatilises to a considerable extent, even in six minutes, and condenses in small spheres. Manganese, with a current of 380 amperes and 80 volts, volatilises very readily; 400 grammes of the metal left only a small residue of the carbide after heating for 10 minutes. Iron, with 350 amperes and 70 volts, volatilises, and condenses as a grey powder mixed with some very brilliant malleable scales. Uranium, with 350 amperes and 75 volts, volatilises readily, and condenses in small non-magnetic spheres, free from carbon. Silicon volatilises with 380 amperes and 80 volts, and condenses in small spheres, mixed with a grey powder and a small quantity of silica. Carbon, with 370 amperes and 80 volts, rapidly changes into graphite and then volatilises, condensing in very light, thin, translucid, maroon-coloured plates, similar to or identical with the maroon-coloured variety of carbon observed by Berthelot. It burns easily in oxygen. Calcium oxide, with 350 amperes and 70 volts, volatilises after eight or ten minutes, and with 400 amperes and 80 volts it volatilises in five minutes. The oxide condenses entirely as an amorphous powder. With 1,000 amperes and 80 volts, 100 grammes of the volatilised oxide can be obtained in five minutes. Magnesium oxide is more difficult to volatilise than calcium oxide, and its boiling point is near its melting point. With 360 amperes and 80 volts, it gives off a quantity of vapour; and with 1,000 amperes and 10 volts, distillation becomes very rapid.

The Chloride Storage Battery.—This battery, of which a description was recently given before the Electrical Section of the Franklin Institute, is so called because the plates constituting the element are made up of tablets cast from fused chlorides of lead and zinc, held together by a frame or rim of antimonious lead. After they are cast, they are reduced so that the lead alone remains in a pure metallic, spongy form. This chemical change is brought about by putting the plate in a bath of chloride of zinc in connection with a slab of metallic zinc which forms a primary battery—the zinc acting as a positive element, while the moulded plate constitutes the negative element. The resulting electro-chemical action causes the withdrawal of the chloride of zinc from the tablets by simple solution in the bath, and the combination of the chlorine of the chloride of lead with the zinc, forming chloride of zinc. Thus the chloride of lead in the tablets constitutes the material which becomes active by electrical disintegration through being connected with the zinc plates in the bath of chloride of zinc. When this reduction is complete, a number of plates is set up as positives in a bath of dilute sulphuric acid, plain lead plates being used as negatives, and a heavy current passed through them for several hours. When the plates are removed from this bath they are next charged continuously in connection with the plain lead permanent negatives for several weeks or until the crystalline lead has been completely converted into peroxide of lead. Positive plates are then set up with the requisite number of negative plates to form cells, which, after being charged a few times, are then ready for shipment. The function of the chloride of zinc in this process is twofold. In the first place, it is impossible to cast plates of chloride of lead without it, as the casting on cooling falls to pieces, so that the admixture of chloride of zinc is absolutely necessary on this account. In the next place, by the use of chloride of zinc it is possible to so control the density of the plate as to produce any desired porosity, and as within certain limits the capacity of a plate is proportional to the porosity, this use of chloride of zinc is of vast importance. In the manufacture of the ordinary red lead or pasted plate, the density of the material depends upon the pressure used in entering the red lead into the grid, and consequently the plates are seldom, if ever, uniform. In the chloride cell, on the other hand, the tablets are absolutely uniform. The mixed chlorides on cooling crystallise into a hard stony substance, and after reduction the metallic lead is left in the form of the needle-shaped crystals running through the plate perpendicularly to the surface; the elimination of the chlorine and zinc provides minute cell-spaces around these crystals, so that an immense surface is offered for the absorption of oxygen in the forming process. The capacity of cells of this type is from five to six ampere-hours per pound of plate, and the discharge rate corresponding to this is one-half an ampere for each pound of plate, a higher rate than recommended for any other lead element. At this rate the watt hour efficiency is from 75 to 85 per cent. Special care is given to the insulation of the plates, it being well known that short-circuiting is one of the main causes of trouble in storage batteries. To overcome this, the positive plate is enveloped in woven asbestos cloth, and between the positive and negative plates is a perforated grooved board of insulating material with perforations which are opposite the pieces of active material in both plates, leaving a free circulation of the electrolyte between the plates and at the same time keeping the asbestos cloth pressed against the face of the positive one, thus holding the peroxide always in position. One of the great advantages claimed for this type of battery is its applicability to cases where there is a large variation in load and consequently in discharge.

ROBERT PERCY SELLON.

Among the electrical engineers who will take front rank during the end of the nineteenth century the subject of our sketch will be prominent. Mr. Sellon was born at Poonah, in the Bombay Presidency, India, in 1863, being the son of the late Colonel Robert Sellon, of the Royal Engineers. He was educated at Blackheath and at Bradfield College, Berks.; and in 1879 was a student at the City and Guilds Technical Institution, passing through the course of electrical technology under Profs. Ayrton and Perry. He served his time in the works of the Anglo-American Brush Electric Light Corporation on their establishment in this country, and joined the technical staff of the company afterwards. In this capacity he had charge of the company's prominent exhibits at the Crystal Palace electrical exhibition of 1882, and was for many years engaged in putting down some of the earliest installations of Brush plant in this country, and was responsible for the lighting of H.M.S. "Colossus," the first man-of-war in the British navy equipped with incandescent lamps throughout, with search-lights actuated from the same dynamos—the course now always adopted. Mr. Percy Sellon has visited all the continents and most of the countries of the world in connection with the Brush Electrical Engineering Company's interests, and their extensive foreign and colonial businesses are largely the result of this work. In 1890 he was appointed assistant manager of the Brush Company; and on the retirement of Mr. Garcke from the managership, Mr. Percy Sellon was appointed joint manager with Mr. J. S. Raworth. Mr. Sellon is a member of the Institution of Electrical Engineers and of the Physical Society.

MOTOR GEARING FOR ELECTRIC TRAMCARS.

(Concluded from page 442.)

The remaining types of toothed gear that have been employed for electric tramway motor work are practically only two in number—viz., worm gear and bevel spur wheels.

The former—used with some amount of success on the Blackpool and Brighton lines, where small powers only enter into account—has had a warm advocate in Mr. Anthony Reckenzaun (whose lamented death is noticed elsewhere in this issue); but even with carefully-designed worms and worm wheel the efficiency of this gear—at a speed, say of 750 revolutions, suitable to tramway work—does not in practice exceed 85 per cent., a result in no way better than that which ought to be obtained with ordinary well cut spur gear. Moreover, it has the disadvantage of requiring the use of a thrust bearing to take the longitudinal strain, from which fact probably arises the low efficiency owing to increased mechanical friction. Then again, if the worm is designed for efficient motion as a driver, it is not suitable for being driven, and, therefore, the gear ought to be cut out of action when the car is going down hill under the action of gravity.

The three advantages of this type of gear are not, however, unimportant: in the first place, it runs with remarkable quietness and ease when kept well lubricated; secondly, it may be covered over and protected from dust or mud with greater ease than any other form of gear; whilst in the third place, the ratio of speed reduction is much higher than with ordinary spur gear, and, therefore, *the motor may be run at a higher* velocity, with perhaps less weight for a given output and efficiency. The ratio of speed reduction in a well-designed worm gear need never be less than, say, 8 to 1, so that a speed of 750 to 800 revolutions per minute is quite easily reached by the motor.

The dimensions of a worm and worm wheel suitable for electric traction work are given as follows by Mr. Reckenzaun:

Worm.	Worm Wheel.
Diameter, 6in.	Diameter, $15\frac{1}{4}$in.
Treble thread, 6in. pitch.	Number of teeth, 24.
Turned out of solid steel.	Cast in phosphor bronze, with cut teeth.

These particulars may be compared with some dimensions of straight-toothed spur gear wheels, as, for instance, the pinions upon armature axles. Such range in size

	Diam.	Width of face.	No. of teeth.	Bore.	Key-way.
From ...	$4\frac{3}{4}$in. ..	$3\frac{1}{4}$in. ...	17 ...	$1\frac{5}{8}$in.	... $\frac{3}{8}$in.
To	$6\frac{3}{4}$in. ...	5in. ..	18 ...	$2\frac{3}{8}$in. and 2in.	... $\frac{5}{8}$in.

An intermediate size of armature pinion, such as would be employed on what is called the W.P. 30 type of Thomson-Houston tramcar motor, measuring $5\frac{1}{2}$in. diameter, $4\frac{1}{2}$in. on face, with 14 teeth, and $2\frac{1}{4}$in. bore, is now being made out of fluid compressed steel. The billet from which it is formed measures in the rough about $7\frac{1}{2}$in. × $3\frac{5}{8}$in., and a hydraulic pressure of 40 tons to the square inch is said to be employed to mould it into the proper shape.

With regard to bevel spur gear, there is not nearly so much to say in its favour. The efficiency seldom, if ever, rises above 80 per cent., whilst the space taken up exceeds that of the worm gear. A recent form of bevel gear employed for traction work had the following dimensions:

Pinion.	Axle Gear Wheel.
Width on face, 5in.	Width on face, $5\frac{1}{2}$in.
Smooth cast steel, teeth uncut.	Double shrouded teeth, uncut. Smooth cast steel.

The only, or chief, advantage afforded by bevel gear is that greater freedom or scope is allowed for suitably placing the motor; and against this must be placed its low efficiency and the mechanical disadvantages of small pinions and weak teeth.

One of the most important questions which have required solution in regard to the mechanical gears for use in electric tramway work has been the problem of double *versus* single reduction of speed. It may be regarded, however, as being by now settled very definitely in favour of a single reduction, and the reasons for this become evident when we consider the greater simplicity and efficiency of the latter. Putting aside all question of the employment of belts, or other friction devices, the real struggle has been fought out between single and double reduction toothed gears. With regard to worms and worm wheels, a single reduction is enough, and the total efficiency of motor and gear combined is in practice, or ought to be, about 77 per cent., allowing 94 per cent. for the motor at 750 revolutions per minute and an average of 82 per cent. for the gear.

With spur wheels, however, the high speed of the early motors rendered necessary at first a double-reduction arrangement, and the combined efficiency of such a motor with two sets of gear seldom or never surpassed 70 per cent., inclusive, that is, of gear and journal losses, as well as those in the motor itself. A single-reduction system, on the other hand, is in poor condition when it cannot show results at least equivalent to those given by worm gear, or, say, 76 per cent. Taking two extreme cases of double and single reduction methods, such as, for instance, that at Bessbrook and the Thomson-Houston modern standard, we have for equal output, say, 20 h.p., the following details:

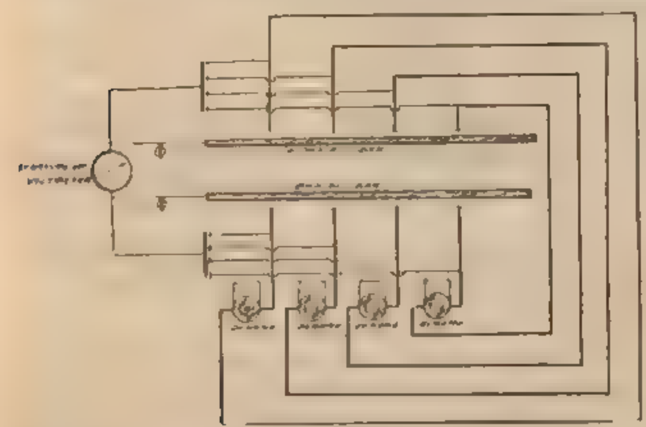
	Speed revs. per minute.	Efficiency.	Weight, cwts., of motor.
Bessbrook......	850	90 per cent.	24
T.-H.............	450	91 per cent.	17

The efficiency of one set of gear wheels probably does not exceed 85 per cent. in practice, so that the combined efficiency of the double-reduction motor and gear averages about 90 × 85 × 85, or, say, 65 per cent. only. The single-reduction motor will, on the other hand, give at least

76 per cent.—that is, 91 × 85. It may be said that the Bessbrook line does not offer a fair sample of double reduction methods since it was a pioneer enterprise, and employed motors not only of a heavier but also of a less efficient type than would now be installed for the same output. So long, however, as the increased efficiency in the high speed motor is only 3 or 4 per cent. at the outside in excess of what can be obtained in machines running at half the speed, the double-reduction system must inevitably give way, if for no other reason than because the efficiency of spur gear does not in practice average more than 85 per cent.; the other types of mechanical connection between motor spindle and car axle are still less efficient, and, therefore, would emphasise the difference. Of course, throughout these remarks the term "efficiency" has been used in connection with motors presumed to run at full load or with maximum efficiency.

POLARITY TEST FOR CENTRAL-STATION USE.

Where shunt dynamos are used in parallel it is very desirable to have some simple and obvious means of testing the polarity of any machine that is to be added to those already on the circuit The diagram given below will explain itself. Most installations have a starting-up voltmeter that may be connected to any individual machine.



All that is required is to connect the positive terminal of starting-up voltmeter to positive omnibus bar through an incandescent lamp, and the negative terminal in a similar way to the negative omnibus bar. Then while the new machine is not excited, and with the starting voltmeter on, each lamp will glow with half the voltage of the circuit, and so present a red light. If the dynamo excites up with right polarity the lamps will gradually be extinguished; on the other hand, if the dynamo be reversed, each lamp will receive its full voltage of 100 volts, and burn normally. With slight and evident alterations, this method may be adapted to places where the three or five wire systems are in use. It should be pointed out that it is advisable that the voltmeter circuit should not be broken unless the brushes of dynamo are down, and that the lamp connections do not affect the voltmeter readings when the voltmeter switches are in. L. LE GROS HORNE.

POLYPHASE ALTERNATE CURRENTS.

M de Chasseloup-Laubat, in the *Compte Rendu* of the Société des Ingénieurs Civils, enters into a long comparison between the distributions by continuous and alternating currents. After alluding to the prominent differences between the two systems as to use of motors in the former and efficiency and simplicity of the latter, he deals with the most frequent and complex case—distribution in towns. Dividing the systems at present employed, we have: (1) alternate currents; (2) continuous currents without accumulators, and (3) continuous currents with accumulators. He deals with each separately, giving diagrams.

1. DISTRIBUTION BY ALTERNATE CURRENTS.

The facility of transformation of these currents permits the use of enormous pressures concentrated on circuits perfectly isolated. A considerable saving in copper is thus assured, while having small line losses. For instance, the dynamo giving 100 volts may have an efficiency of 90 per cent.; this pressure can be raised to 10, 25, or even 30,000 volts in a transformer of 96 to 97 per cent. efficiency—giving a total generator efficiency of 87 per cent. The line loss, with a relatively small section of copper, will be not over 5 per cent. One or several sub-stations will receive this current and reduce the tension to 1,000 or 2,000 volts, with a loss of 3 or 4 per cent. In such a system the transformer load can be kept high, and we have 80 per cent. of the energy delivered at the sub station switchboard The loss in the network will also be small at 1,000 or 2,000 volts without having large sections of copper.

The high efficiency achieved to this point is unfortunately diminished by the house transformers which reduce the pressure to 100 volts. As these hardly ever work at full load, their average efficiency is not much over 50 per cent. Arrangements devised to obviate this loss have not as yet achieved practical success, or at least cause complications which have prevented their adoption.

The daily consumption in towns generally follows a law analogous to that indicated in Fig. 1. As is seen, the total plant is occupied over a very few hours, and the mean specific efficiency (*i.e.*, its utilisation) is very low.

In this class of distribution there is a direct connection between engine and lamp—there is, as one may say, a want of elasticity. As security of working is required, this necessitates spare plant, which again reduces the already low utilisation of the machines.

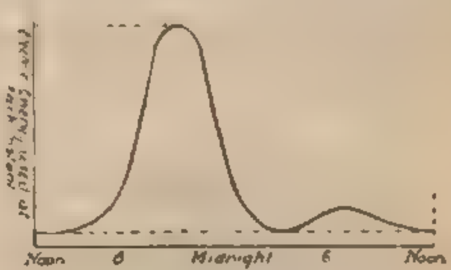


FIG. 1.—Typical Load Diagram.

2. DISTRIBUTION BY CONTINUOUS CURRENTS WITHOUT ACCUMULATORS.

Except for the possibility of using current for electrolytic purposes (a rare occurrence) and especially for driving motors of easy manipulation and high efficiency, this method is not superior to the first. Such high tensions cannot be employed, while the continuous-current transformers having moving parts require constant attention. They must, therefore, be placed in the sub-stations and not in the houses, and from this it results that the distribution must be at 110 volts, or 220 in a three wire system, and that the cost of network will be high—in copper and in loss of energy. What has been said as to low utilisation of plant in the alternate-current distribution applies equally to this system.

3. DISTRIBUTION BY CONTINUOUS CURRENTS WITH ACCUMULATORS.

Although this has been attempted, it does not seem to be practical to use accumulators as transformers. As the total energy must pass through the accumulators there results a total loss of 25 per cent., and at high tensions the insulation of the batteries is difficult to maintain. The batteries must be placed in sub-stations, as they cannot go in the houses. These sub-stations may be either in shunt or in series at high potential. The following are the different arrangements possible to adopt.

(*a*) *Sub-Stations in Series.*—The high-tension current here must be constant in strength; and as the consumption of the different sub-stations is not the same, as soon as one battery is charged it is cut out of the charging circuit to diminish the resistance of this circuit. But the loss in the line, L, is still the same whatever the number of batteries,

and the cutting-out operation is delicate. The distribution, $D^1 D^2 D^3$, may be on two, three, or five wires.

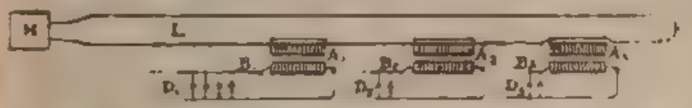

FIG. 2.—M, machine producing high-pressure current. L, line feeding sub-stations. A^1 A^2, batteries being charged. A^3, battery charged. B^1 B^2 B^3, batteries feeding low-tension network (D^1 D^2 D^3.)

(*b*) *Sub-Stations in Parallel.*—This system requires constant pressure in the high-tension wires. The E.M.F. of each battery must be equal to this pressure; during discharge each battery is divided in groups run in parallel. This system led to the use of cells with a large number of small plates, which is inconvenient, and in other respects it seems less practical than the preceding arrangement.

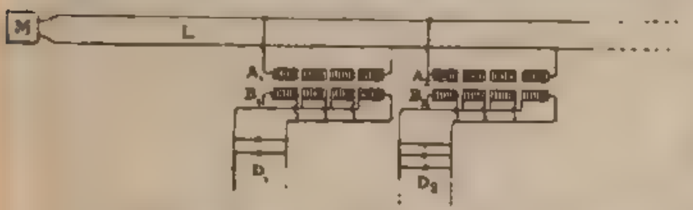

FIG. 3.—M, high-tension machine. L, line supplying sub-stations. A^1 A^2, batteries in charge. B^1 B^2, batteries feeding low-tension networks (D^1 D^2); these batteries are divided in groups coupled in parallel. D^1 D^2 are with two, three, or five wires.

The line loss here diminishes with the diminution of energy supplied. This system has never been employed, at least to the author's knowledge.

(*c*) To avoid the transformation of the totality of that electrical energy and to diminish by half the number of accumulators, the following arrangement has been made:

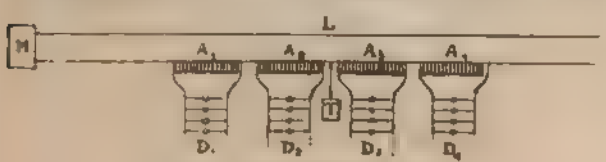

FIG. 4.

The high-tension current passes through the whole of the batteries of the different sub-stations placed in series: the secondary circuits are branched from the terminals of each battery.

The difficulty of insulation—which only exists in systems (*a*) and (*b*) during charge and when there is no communication between battery and secondary circuit—here becomes permanent. Moreover, although the difference of pressure between the two wires is only 100 volts, that between one of the wires and earth may be considerable,

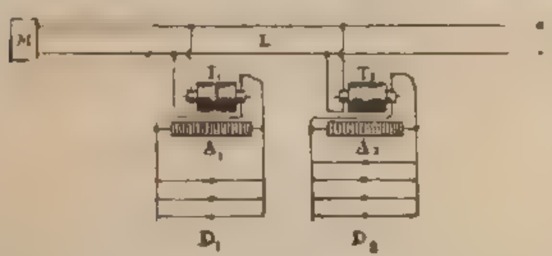

FIG. 5.

and safety to customers is not assured. The maximum difference must not exceed the limit of danger; and this limits the high tension to 400 and 500 volts. In this case recourse is had to the five-wire system. The middle of the circuit, T, can be put to earth, but the insulation is then more difficult, and there is danger of burning up the apparatus.

(*d*) When, for reasons of economy, high-tension circuits must be used, it seems more reasonable to use *continuous-current transformers* in sub-stations with a battery in *parallel to each dynamotor.*

The dynamotors, T_1 T_2, may be placed either in parallel or in series on the high-tension circuit, L. The distribution, as before, can be with two, three, or five wires.

Here, not only are the secondary circuits working at low pressure, but they are at a small difference of potential with the earth. Personal safety and security of plant are both easier to attain.

We can thus employ the highest pressures possible to produce. As, moreover, the efficiency of these machines is over 90 per cent., and only a part of the energy passes into the accumulators, a satisfactory economy is assured.

In any case, whichever of the systems, (*a*), (*b*), (*c*), or (*d*), are used, the utilisation of the plant will be excellent.

As is seen from Fig. 6, the plant can work at full load continuously, or, for instance, 20 hours out of 24. They thus work at their highest efficiency, and are utilised to the maximum.

Sometimes the machines supply direct (or by intermediary of transformers) the electric energy required for distribution at the same time as they charge the cells. Sometimes, on the other hand, the cells come to the aid of the machines by giving back this energy. In case of stoppage the cells will assure service during a certain time, and therefore there need be little spare plant.

The accumulator here plays the part of intermediary, and the system has the required elasticity of which mention has been made.

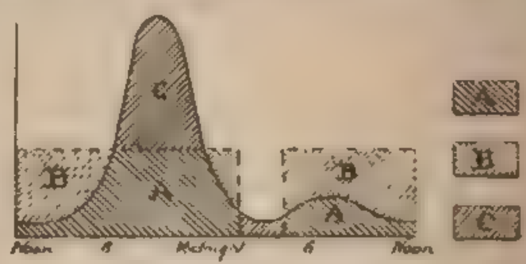

FIG. 6.—A. Electric energy supplied by the machines to the distribution. B. Energy supplied to accumulators. C. Energy given back by the accumulators to the distribution.

CONCLUSIONS.

To sum up, this comparison between alternate and continuous currents shows that:

1. Alternate currents are preferable for long distances, as much on account of the high tensions that can be used as for ease of transformation.

2. In the secondary networks at low tension, continuous currents are superior because they allow the use of accumulators, whence results a better utilisation of plant and greater security of working.

This leads to the expression of three desiderata:

I. To store electric energy supplied in the form of alternate currents.

II. To transform alternate into continuous currents.

III. To transform the energy supplied by alternate currents into mechanical work.

It may be remarked that the solution of problem III. involves the solution of II., as an alternate-current motor could drive a continuous current. So, also, the solution of II. affords a solution to I. by the transformation into continuous current and the storage of the energy of this latter.

Nevertheless, we preserve the original form to these three desiderata, not to prejudice their direct solution.

I. Speaking commercially, the first desideratum does not seem to include the direct solution for the moment.

II. MM. Hutin and Leblanc have been long occupied with the possibility of accomplishing this direct transformation, and have published very interesting articles thereon. Quite lately they have set forth a general method for transforming alternate into direct currents. This method seems now quite practical and particularly convenient in the case of employment of polyphase currents.

We shall study later the different methods of transformation of these currents.

This problem, being solved practically, enables us to adopt the mode of distribution shown in Fig. 7.

An alternator first produces polyphase currents at low pressure (triphase, for instance).

A transformer raises this to 10,000 or 15,000 volts, at which it is transmitted to the distant point. The current is then let down to 2,000 volts by a transformer and distributed to sub-stations, which can be placed in series or in parallel. In the sub-stations are placed the special apparatus mentioned to transform these polyphase into continuous currents; and further, a battery of accumulators is placed in parallel with these latter machines.

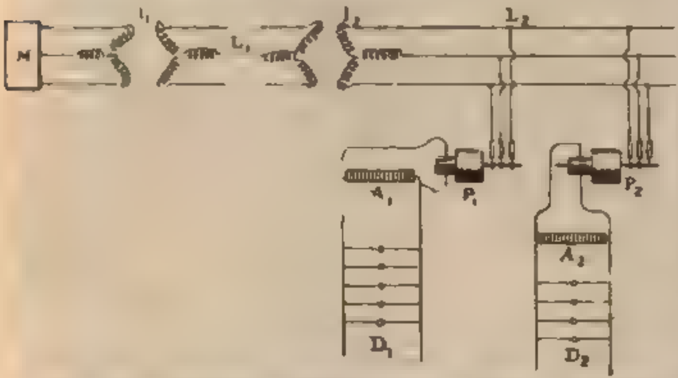

FIG. 7.—M, polyphase generator of low tension. T_1, step-up transformer. L_1 long-distance transmission. T_2, step-down transformer. L_2, circuit feeding sub stations. P_1 P_2, transformers in sub stations transforming polyphase currents of high tension into low tension continuous currents. A_1 A_2, accumulators in parallel. D_1 D_2, distribution at low pressure, continuous current (two, three, or five wires).

It seems preferable to place the sub-stations in parallel rather than in series, because of the independence of each other thus realised. If the polyphase transformers, P_1 P_2, included an exciting circuit requiring continuous current, this could be obtained from accumulators.

The advantages of all the methods of distribution hitherto described are united in the above system.

The alternator and the different transformers work at full load, and consequently at maximum efficiency and utilisation. The security of working is great, owing to the use of accumulators. The transmission to long distance is not too onerous, owing to the high tension employed. Lastly, the security to person is safeguarded, as the conductors accessible to the consumer are all at low tension.

(To be continued.)

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE IV.

(Concluded from page 450.)

The High Pressure Reservoir at Bessinges.—When the high-pressure system was first put in operation a constant pressure was maintained in the mains by constantly pumping in excess of the demand, and allowing the surplus to flow away through a relief valve. This involves a constant waste. To further moderate fluctuations of pressure, four large air vessels (additional to those at the pumps) were erected. These were 5ft. in diameter and 39ft. high, and were kept charged with air by a Colladon compressor. When it became a question of driving the electric station by turbines driven by water from the high pressure system, the need of a storage reservoir became pressing. At four kilometres from Geneva a site was found, at an elevation of 390ft. above the lake, and it was decided to construct a reservoir capable of storing the discharge of three groups of pumps working through the night. The discharge of the pumps is 34,000 cubic feet per hour, or 442,000 cubic feet per 13 hours, during which, if there were no means of storage, they would be put out of action.

The reservoir is a covered reservoir, capable of containing 453,000 cubic feet. It stores, therefore, 5,573 gross horse-power hours of energy. Allowing for the loss at the motors driven by the pressure water, the reservoir will furnish about 800 effective horse-power for five hours. It serves as a perfect regulator of pressure. A float with electric signal and recording apparatus shows constantly in the pump-house the condition of the reservoir.

Hydraulic Pressure Relay or Compensating Pressure Regulator.—The 18in. pipe main from the pumping station to the reservoir at Bessinges being four kilometres in length, there would be a difference of pressure in the mains in Geneva equivalent to the friction of eight kilometres of main, according as water was being pumped up to or flowing back from the reservoir. This would not have been very serious if all the motors driven by the water had been supplied by meter. But the larger motors are supplied by gauging, the quantity of water used being computed from the area of the orifices of discharge. Variations of head would have involved a variation of the quantity of power developed at the motors amounting to 20 per cent. This would have hindered the development of that method of estimating the charge for water.

To prevent this variation of head, Colonel Turrettini devised a centrifugal pump relay, shown diagrammatically in Fig. 22, which comes into action automatically, and increases the pressure whenever the water is returning from the reservoir to the town. The centrifugal pump, which forms part of the main, is driven by a turbine so regulated for speed that a constant pressure is obtained on the town side of the pump. The pump receives at the maximum 635 cubic feet of water per minute, and can give to the stream passing through it an increase of pressure of 30ft. The turbine works with 380ft. of head, and can exert 120 h.p.

The sluices of the turbine are governed by an automatic pressure regulator. The pressure in the main acts on a piston controlled by a spring. According to the position of the piston, the turbine sluices are open more or less. The movement of the piston actuates the valve of an hydraulic relay which operates the turbine sluices. During the filling of the reservoir the centrifugal pump is at rest, the water merely flowing through it. When water flows back from the reservoir the turbine begins to drive the pump so as to increase the pressure in the main. The arrangement has worked with perfect success.

The Motors Used in Geneva.—The original motors used in Geneva were Schmid pressure engines, and these are still used for small powers. They use a quantity of water which depends on the speed only and not on the work done. Hence they are uneconomical with light loads. They are convenient and cheap, they can be run at any speed, and they act as meters of the quantity of water used. A counter on the pressure engine recording the number of revolutions, gives the means of ascertaining accurately the quantity of water used. At full load their efficiency is 80 per cent.

For all larger motors impulse turbines are used. The maximum efficiency of these is 75 per cent., and it is not much less with light loads. They occupy little space, and can be perfectly governed to constant speed by the ingenious relay governors of Messrs. Faesch and Piccard. In Geneva the question of speed regulation was found to be an important one. The industries connected with watchmaking required motors running at constant speed.

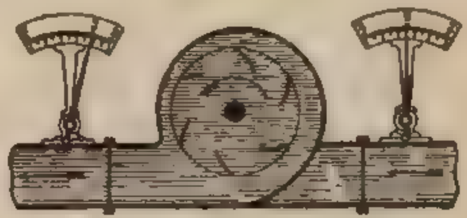

FIG. 22.

The Electric Lighting Station.—In 1887 the City Council came to an arrangement with a company for supplying electricity. It was part of the arrangement that the company should use pressure-water, supplied by the town, as motive power in all its installations. The pressure-water is supplied to the company by meter, at a price of two centimes per metre cube, with a minimum of 40,000 cubic metres annually. This is equivalent to a little more than £3 per effective horse-power per annum. The advantage to the town is that their pumping machinery can be run constantly, night and day, the energy, which would otherwise be wasted, being stored. The electric company, on the other hand, got power at a cheap rate, and their turbines being driven by high pressure are convenient and cheap, and run at an extremely constant speed.

Under the arrangement an electric station has been installed in the old pumping station, no longer required for its original purpose (see Fig. 21). There are three impulse turbines of 200 h.p. each, and each turbine drives two dynamos directly coupled to it by Raffard couplings. There is also a 25 h.p. turbine and dynamo for day work. It is the system of reservoir storage which makes this hydraulic driving of the dynamos possible and economical. They could not be driven so conveniently by the large low-pressure turbines in the river, with the very varying head which they have to utilise, nor could power be spared to drive them, except by utilising the motive power of the flow of the river through the night.

LECTURE V.

TRANSMISSION BY COMPRESSED AIR.

Compressed air has been employed in engineering operations for a long period. The earliest important application was the diving bell. This is believed to have been used in the sixteenth century. Smeaton, in 1788, and Rennie, in 1812, used diving bells and air compressors in important operations. Subsequently, compressed air was applied in sinking bridge piers. Cubitt employed compressed air in sinking the piers of Rochester Bridge, in 1851; and Brunel a similar process at Saltash in 1854. Compressed air was applied in driving the Thames Tunnel by Brunel and in driving the Thames Subway, by Barlow. It has been used

* Howard Lectures delivered before the Society of Arts.

since in several similar works of a difficult character. The shaft of the Marie Colliery, at Seraing, was sunk by means of compressed air, by the firm of John Cockerill, in 1856.

The application of compressed air as a motive power in transporting goods seems to have been first suggested by Medhurst, in 1810, and by Vallance, in 1818. Some early pneumatic railways were built; later, similar methods have been revived in the systems for transmitting messages and parcels through pneumatic tubes in London and Berlin.

Papin appears to have considered the transmission of motive power to a distance by a vacuum method in 1688. Triger actually transmitted motive power by compressed air a distance of 750ft. at the mines of Chalonnes in 1845. Soon after, compressed air was used in several collieries. The greatest impetus to the application of compressed air as a means of distributing power resulted from its employment in working boring machinery in tunnels. Brunton, in 1844, suggested this application, and, in 1852 Prof. Colladon, of Geneva, proposed the use of compressed air in the construction of the Mont Cenis Tunnel. It was, perhaps, at Mont Cenis that compressed air was first used for motive power purposes on a large scale. M. Sommeiller, in association with M. Kraft, made extensive experiments at the works of John Cockerill at Seraing, and with the data so obtained the whole of the machinery for compressing, transmitting, and utilising compressed air at Mont Cenis was designed and constructed at Seraing. At first, for compression, a kind of hydraulic pneumatic ram was used. In 1861 this was superseded by water piston compressors, driven by turbines. The air was transmitted a maximum distance of 20,000ft. to work the drills. The air pressure used was seven atmospheres (105lb. per square inch). There were at Mont Cenis air motors worked expansively, the cylinders of which were heated externally to prevent freezing. In the construction of the St. Gothard Tunnel, in 1872, still more powerful air-compressing machinery was employed. The compressors were at first designed to be of small size, to run at a high speed, and to be cooled externally; but with a short stroke and quick speed there is not time for the heat developed by compression to be abstracted through the cylinder wall, and a spray injection, suggested by Prof. Colladon, was added.

In 1887, Mekarski used air compressed to 25 or 30 atmospheres, in conjunction with a small amount of high pressure steam, to drive tramway cars, and he was one of the first to use compound compressors.

In 1877, at Vienna, and in 1881, at Paris, M. Popp installed a system for working and regulating a great number of clocks by impulses of compressed air conveyed in pipes from a central station. A demand arose for a supply of the compressed air for working small motors, and this proved so successful that there has been developed in Paris the most important system of power distribution hitherto carried out. In Paris, motive power is transmitted to industries of every kind over a large area by air compressed at a central station, and even sub-stations for electric lighting are driven by air motors. It is interesting that in Paris a system of distributing motive power by vacuum carried out by M. Boudenoot, has been successfully in operation since 1885. The motors are worked by atmospheric pressure and exhaust into pipes, in which a vacuum is maintained by air pumps at a central station. A system of pumping sewage at a number of scattered sub-stations by compressed air supplied from a single compressing station has been developed by Mr. Isaac Shone, and is in operation at several towns in this country and the United States, and at Rangoon.

Compressed air transmission is a perfectly general method of distributing power for all purposes. Whether, in any given case, it is the most advantageous, the least wasteful of power, or the cheapest in working cost, depends on various circumstances. M. Hanarte believes that it is—and will continue to be—the most economical method of transmission to considerable distances.* The loss in the air mains is very small. The motors worked expansively are efficient. The mains can be carried by any path, and differences of elevation between the compressing and working points do not sensibly affect the result. In hydraulic transmission the water must be collected, stored, and in some cases filtered; and having actuated a motor, means must be found for removing it. But air is everywhere available, and can be discharged anywhere without causing trouble. Compressed air has peculiar advantages in the case of underground transmissions. It has been used to replace manual labour in situations where hardly any other motive power could have been employed. In driving a tunnel at a mine at Sacramento, for instance, the cost was reduced to one-half, and the rate of boring was three times as fast when compressed air machinery replaced hand labour. In such cases the advantage is so great, even with uneconomical machinery, that the inducement to adopt very perfect machinery is absent. Hence, much of the air compressing plant at mines has been unnecessarily inefficient and wasteful of power. In many cases, air compressing plant has been driven by water power, and this also has tended to a neglect of the conditions necessary for economical working. Mr. Savage argues, with reference to the Terni Steelworks,† that the common objection to the use of compressed air on the ground of waste of power, loses much of its force when the compressors are worked by an almost costly supply of natural energy such as water power. It is unfortunate for the reputation of the system of transmission by compressed air that the rough purposes to which it has been applied, the indifference to waste of power in mining and tunnelling operations, and the preference for simple and cheap machines, has delayed and hindered the improvement of compressed air plant.

A good deal was done to improve air-compressors by Sommeiller, by Dubois, and François, and by others in the large plants constructed for Mont Cenis, for the St. Gothard works, and for some collieries. In the distribution of power in towns still further consideration has been given to the question of economy of working. But here again it has been very unfortunate that in both the great installations in Paris and in Birmingham, there were conditions of development very unfavourable to the complete and fair trial of compressed air as a means of transmission. It is reasonably certain that with greater attention to scientific principles better results are attainable than have hitherto been reached in the use of compressed air.

For the special purposes to which power distribution is applied in London, the high pressure hydraulic system has great advantages. Where local conditions permit the construction of high level reservoirs, a system like that in Zurich and Geneva of hydraulic distribution is perfectly successful; but in more numerous cases, compressed air is likely to prove preferable to hydraulic transmission. It is also the most important rival of electrical distribution. There are at present extremely few cases where electrical distribution of power has been carried out; and though enough is known of the capabilities of electrical transmission to show that it could be adopted on a large scale with complete mechanical success, the cost of the distribution of power by electrical methods is at present very imperfectly determined. For long distance transmission, and where cheap overhead conductors can be adopted, no doubt electrical methods have an important field of application; but up to the present time, and excluding transmissions for lighting, an enormously greater amount of power has been actually distributed by compressed air than by electricity. So far as can be judged at present, in the case of distribution of power in towns, and especially where work has previously been done by steam-engines which can be converted into air motors, in such cases compressed air is likely to prove a more convenient and cheaper means of power distribution than electricity.

General Considerations on Compressed Air as a Means of Distributing Power in Towns. The desiderata in a system of power distribution in towns may be shortly enumerated as follows: (1) The possibility of indefinitely subdividing the power distributed and measuring the supply to each consumer. (2) Minimum first cost of distributing mains, and minimum loss of energy in distribution. (3) Simplicity, cheapness, and efficiency of the motors required by consumers of power; and, especially, it is important that the motors should require little attendance and involve little risk. (4) Freedom from danger to life or property when accidents occur to motors or distributing mains. (5) Facility of adaptation to various requirements additional to the supply of motive power. This is important, both from the additional revenue obtained, and because the more various the applications satisfied the better are the conditions of working at the central station. The fluctuations of demand are diminished and the load line improved.

A compressed-air system meets these conditions on the whole more completely than any other system hitherto carried out. Experience in Paris shows how great the facility is for subdividing the power in a compressed air system. There are motors ranging from 150 h.p. to less than $\frac{1}{12}$ h.p. (45 foot pounds per second). The majority of the air motors are, in fact, of less than 1 h.p. These can be started and stopped by merely opening or closing the supply valve, and the measurement of the air used presents no practical difficulty. In Paris and in Birmingham the air is measured by meters, which are not costly, and which are accurate enough to give satisfaction. As to the distributing mains, it may be pointed out that in an air system no return main is required, the air being discharged at the working point without creating any nuisance. In a steam distribution a return main is desirable to avoid heat loss, and in an electric distribution a return main is necessary. Air mains are less costly than hydraulic mains or steam mains. Under what conditions they are less costly than electric mains is a question yet to be determined. Probably they are much less costly than electric mains, except in cases where high electric pressure can be used and overhead conductors. M. Solignac has considered the case of the transmission of the 70,000 h.p. from Billancourt to the Place de la Concorde, at Paris, a distance of 4½ miles.* He comes to the conclusion that air mains would cost £112,000, while electric mains, worked at 2,000 volts, would cost £700,000. Even if the energy were required at the terminus in the form of electricity, he concludes that it would cost 20 per cent. less to transmit by compressed air, and generate electricity at the terminus by dynamos driven by air motors than to generate and transmit the electricity from Billancourt. As to loss of energy in the mains, electricity has little advantage over compressed air. The pressure loss in the mains of a town distribution is insignificant. In the Paris system the principal mains have an extension of 35,000 metres (34 miles). The loss of pressure between St. Fargeau and the most distant point of the main rarely reaches 5lb. per square inch. The safety of an air main is obvious, and even a leakage or burst of the main is much less serious, and attended with less damage than that of a water or a steam main. Air leakage is less dangerous than electric leakage. When an air distribution is introduced in a town, power users do not require new plant and need incur no outlay for motors. The boilers—with all their attendant disadvantages of stoking, removal of ashes, cleaning, and risk of explosion—are dispensed with, and the steam-engine, with little alteration, serves as an air motor. If an

* Solignac. "Transport de l'energie par l'air comprimé." Congress International de Mecanique Appliquée, Paris, 1893.

electric system is introduced the old motors must be removed and new motors purchased. Further, if electric motors are themselves of high efficiency, they run at a high speed, and in most cases there is a considerable loss in the gearing required to adapt them to ordinary purposes. For small power users there are rotary motors of simple and cheap construction. Lastly, air motors are so simple that they require when working extremely little attention.

In regard to adaptability to various requirements, compressed air is in a very advantageous position. Electricity supplies power and light, but it cannot be used for supplying heat except at a cost prohibitive in most applications. Gas supplies heat, and power, and light; but for lighting it is open to obvious objections, and for heating and power it is expensive. Pressure-water supplies power and, indirectly, light, if a motor is used to drive a dynamo; but, except where cheap water power is the original source of energy, it is too expensive for most purposes where motive power is required. Steam supplies heat, motive power, and, indirectly, light, if a steam motor is used to drive a dynamo; but it is more expensive than compressed air, and involves more risk and attention.

Compressed air can be supplied so cheaply, that not only can it be used directly as a source of motive power, where that is the commodity required, but it can be advantageously used to drive sub-stations and private installations for generating electricity, for lighting purposes, or for working pumps and ventilating fans. With a water cushion between the air and the lift ram, compressed air is as convenient for working lifts as pressure water. It has been used in working cranes at the Cockerill Works for 20 years. Compressed air is not directly a source of heat, but used for blowing purposes it is an extremely useful adjunct to furnaces. In Birmingham, smiths' fires and cupolas have been worked direct from the air mains without any blowing machinery. A small jet of high-pressure air induces a large stream at lower pressure. In Paris, compressed air has important applications for refrigerating purposes. Besides large refrigerating stores in some restaurants, an air motor is used for driving a dynamo for lighting purposes, and the cooled exhaust from the air motor is used to cool chambers in which food is stored. Lastly, compressed air is already used in working tramways, and it appears likely that much larger applications of this kind are possible.

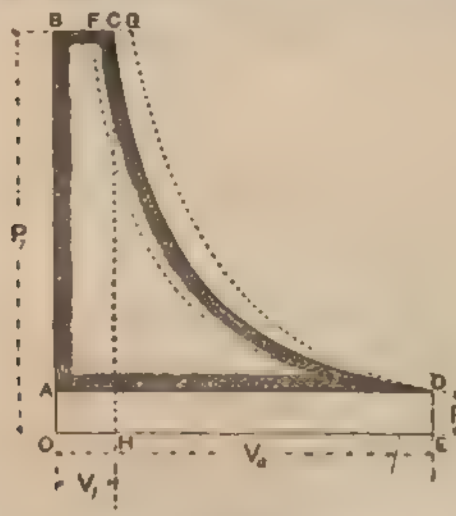

FIG. 23.

General Arrangements of a System of Compressed-Air Transmission.—The arrangements include: (1) A compressing plant driven by steam or water power with air reservoirs of more or less capacity to diminish momentary fluctuations of pressure. The compressors usually require the addition of cooling arrangements for absorbing the heat developed in compression. (2) A system of air mains for distributing the compressed air to the working points. (3) Air motors driven by the compressed air and sometimes provided with reheaters to increase the work done by the air and diminish the cooling during expansion. It is necessary therefore to consider the construction of compressors and their efficiency; the construction of mains and the losses in transmission; and the construction of air motors and their efficiency.

Action in a Compressor.—Consider, for simplicity, a compressor which receives and discharges 1lb. of air per stroke, and let Fig. 23 be its indicator diagram. Let P_a, V_a, T_a be the pressure in pounds per square foot, volume in cubic feet per pound, and absolute temperature of the atmospheric air to be compressed; P_1, V_1, T_1, the corresponding quantities for the air after compression. The quantity $R = V_a/V_1$ is called the ratio of compression.

The compressor in the suction stroke draws in a volume, V_a, of air at the pressure P_a, compresses it according to some law expressed by the compression curve, DC, to the volume V_1 and pressure P_1, and finally expels it into the mains. In general, the compression curve, DC, will be between two curves, DF, DG, corresponding to two limiting cases. If heat is abstracted from the air during compression, so that the temperature remains constant, the compression curve will be the isothermal, DF, defined by the relation—

$$P\,V = \text{constant}.$$

If no heat is added or subtracted during compression, the temperature of the air will rise, and the compression curve will be the adiabatic, DG, defined by the relation—

$$P\,V^{\gamma} = \text{constant}.$$

In ordinary compressors the compression curve lies between DF and DG, and the temperature of the air after compression T_1 will be greater than the initial temperature T_a.

If the compressed air were used in a motor directly adjacent to the compressor in its heated state, there would be no necessary loss due to heating during compression. But commonly the air is used at a distance, and has cooled from the volume BC to the volume BF, and from the temperature T_1 to the temperature T_a before it reaches the working point. The most economical compression therefore for a system of compressed-air transmission would be isothermal compression. The area FDC represents work expended in the compression in heating the air which is wasted before the air is used.

It can be shown that the work wasted in heating the air in the compressor above its initial temperature when the expansion curve is given by the relation—

$$P\,V^{n} \text{ constant},$$

is given by the expression:

$$27{,}710\left\{\frac{n}{n-1}\left[\left(\frac{P_1}{P_a}\right)^{\frac{n-1}{n}}-1\right]-\log_e\frac{P_1}{P_a}\right\}$$

which gives the work wasted in foot-pounds per pound of air.

WORK LOST DUE TO HEATING IN COMPRESSOR.

$\frac{P_1}{P_a}$	P_1 = pressure of compression in lbs. per square in. (absolute).	Work lost in adiabatic compression $n = 1{\cdot}41$.	Work lost in partially cooled compression $n = 1{\cdot}25$.
2	29·4	0·077 $P_a V_a$	0·052 $P_a V_a$
4	58·8	0·322 ,,	0·209 ,,
6	88·2	0·562 ,,	0·363 ,,

It will be seen that the loss increases rapidly, almost as the square of P_1/P_a. This rapid increase of the heating loss has led

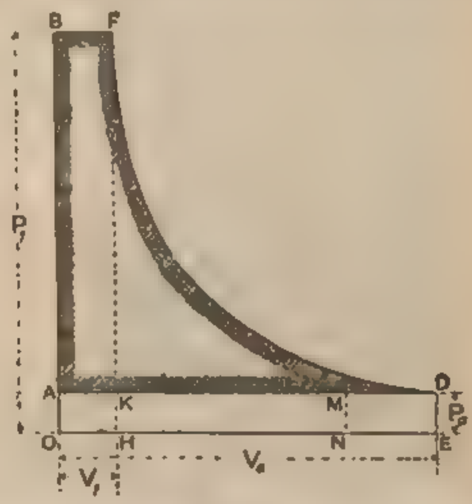

FIG. 24.

many constructors to advise the use of very low working pressures in compressed air transmissions. But that involves an oversight. The increased loss at the compressor, due to a higher working pressure is partly balanced by an increased efficiency of the air motor, so that low working pressures are not necessarily most economical for the whole system.

Case of Isothermal Compression.—The most economical compressor, mechanically, would be one in which the air was compressed isothermally, heat being abstracted during the compression, so that the temperature did not rise. In that case, the heat abstracted is exactly equal to the work done during compression.

The whole work, in a complete double stroke, consists of three parts: (1) The work, OADE, of the atmosphere on the piston during the suction stroke; (2) the absolute work of compression, EDFH; (3) the work of expulsion of the air into the mains, OBFH. In isothermal compression, PV = constant. The effective work expended in driving the compressor, given by the shaded area, ABFD, is the algebraic sum of the three quantities of work just stated. That is

$$-P_a V_a + P_a V_a \log_e\frac{P_1}{P_a} + P_1 V_1 = P_a V_a \log_e\frac{P_1}{P_a},$$

or exactly equal to the absolute work of compression, HFDE. But the heat abstracted during compression is also exactly equal to the area HFDE. Hence the curious result is arrived at that, in the most economical compression, the effective work of compression is entirely abstracted as heat, and wasted. All that the compression has done has been to put the air in a condition to do work in a motor at the expense of its intrinsic energy. The work in the motor is in no sense a return of the work expended in the compressor. Hence the conditions of transmission of power by compressed air are entirely different from those of transmission by pressure-water.

AT THE INSTITUTION.

The winter session of the Institution of Electrical Engineers was inaugurated last week with a lengthy paper by Prof. Forbes, F.R.S., on the subject of electric transmission at Niagara. Before alluding to the general value of the paper there is one question, which on this side of the Atlantic is felt to be a sore one, that may be mentioned. It will be remembered that the company requested certain designs and plans from electrical engineers. The latter readily complied with the request, and undoubtedly a large amount of time, of trouble, and of money was spent in preparing these plans. On consideration, however, of the plans it was found that tariffs interfered with the acceptance of any European design, and so they were thrown aside. The authors received nothing, and have felt that they were badly treated. Some have gone so far as to say the request was issued with an ulterior motive, which, in plain words, was to pick the brains of the world at no cost to the promoters. Prof. Forbes emphatically disclaims any use of the designs sent in so far as the construction of the machines is concerned, and explains in what particulars his design differs from all others. No one for a moment ascribes blame to Prof. Forbes, but the request of the American promoters, on the face of subsequent actions, is not one that can be commended. Prof. Forbes is wise in taking the profession into his confidence, as even during the progress of the work valuable suggestions may be made and tried. The work at Niagara is what Prof. Forbes claims, as important as any engineering work ever undertaken. The utilisation of the waste power at Niagara has been the dream of engineers, and ever since the rise of electrical engineering it has been more prominent, because such authorities as Lord Kelvin, Profs. Ayrton and Perry, etc., early saw the possibilities of power transmission. Prof. Forbes has thrown himself into this work *con amore*, and if success is achieved it cannot for a moment be said it is undeserved. The work is on a grand scale, yet every detail seems to have been carefully examined, not only to see that the purpose required would be effected, but also that the maintenance should be a minimum. Unfortunately, the full proofs of this paper were only distributed while the technical papers were going to press, so that anything like a well-considered opinion is at the moment impossible. The general scope only of the paper can be considered. The author points out he early came to the conclusion that the alternate-current system of transmission was the correct one in this instance, and that the objection to lack of motors has been met by a host of inventions. The critical point, according to Prof. Forbes, lies in the frequency. His investigation led him to the conclusion that the gain is far in excess of the extra cost, and that parallel working is assisted by lowering the frequency, as is the performance of synchronising and other motors. The apparatus at Niagara Falls considered by Prof. Forbes to be the most favourable—hence its adoption by him—is sixteen and two-third periods per second. A large part of the paper is devoted to the consideration of this question,

and will undoubtedly form admirable reading. It does not say much for American constructors to find they decline to construct machines to give above two thousand five hundred volts, and that, therefore, dynamos are to be used generating at two thousand volts, with step-up transformers for the extra high pressure. Prof. Forbes disclaims the obtaining of suggestions from the dynamo designs sent in, and, as previously stated, we do not dispute his disclaimer. We have given concreteness to the remarks flying about, and admitting the absolute accuracy of Prof. Forbes's statement, that does not exonerate the company in its getting plans from Europe. The question of tariff might have been considered in the first place, and the results of the tariffs on cost ought to have been known, so as to save the time, trouble, and expense of those who sent in plans.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE BIRMINGHAM ELECTRIC CARS.

SIR,—From a letter of the Electrical Power Storage Company, it would appear that out of the number of E.P.S. batteries supplied to the Birmingham Central Tramways Company about two years ago two have been regularly working till now, and giving excellent results. This is not according to facts.

On the other hand, the results which have from time to time been published by the Epstein Electric Accumulator Company, Limited, are based on indisputable facts, and their correctness can be easily ascertained. The statements as to the lifetime, reliability, and absence of repairs and renewals were made publicly and confirmed by those best able to judge, being in possession of official figures.

The experience and responsibility of the gentlemen who are entrusted with the management of the affairs of the Birmingham Central Tramways Company should offer a sufficient guarantee that the order given to the Electrical Power Storage Company is coupled with a maintenance clause, and it would be doubting their business capacity if one presumed that the terms of the contract are not more to the interest of the shareholders than the offer made by the undersigned company to work the line and defray all expenses with the exception of permanent way and general charges for 70 per cent. of the gross receipts.

But electrical and tramway engineers would no doubt feel greatly obliged if the information regarding the lifetime, repairs, and renewals of the accumulators, and the financial results to the supplying and maintaining company, were officially vouchsafed from time to time.—Yours, etc.,

L. EPSTEIN, Managing Director.

The Epstein Electric Accumulator Company, Limited.
21A, Blythe-road, West Kensington, Nov 15.

OBITUARY.

THE LATE ANTHONY RECKENZAUN.

It is with the deepest regret that we have to record the death of Mr. Anthony Reckenzaun, which took place early on Saturday, November 11. The death of Mr. Reckenzaun leaves a gap in the professional ranks of the industry which it will be difficult to fill. He had made himself the English authority on all matters relating to electric traction. A brief account of his career appeared in our issue of January 15 last year, which, with the accompanying portrait, we now reproduce. He was born at Gratz in 1852, and received his early education in that town. Like most successful electrical engineers, Mr. Reckenzaun was originally trained as a mechanical engineer. Coming to England in 1872, he entered the employ of Messrs. Ravenhill and Miller, afterwards Messrs. Easton and Anderson. While with Messrs. Easton and Anderson he qualified as a teacher under the Science and Art Department, and established evening classes for the employés. Subsequently he attended lectures at the School of Mines, and at Finsbury. Feeling a great interest in electrical matters, Mr. Reckenzaun made a thorough study of the apparatus at the Paris Exhibition in 1881, then joined the Faure Company, but soon after accepted the position of electrical engineer to the Electrical Power Storage Company. Here he turned his attention to traction, a branch of the industry with which his name has since been intimately connected. Storage batteries were also carefully studied, and their capabilities investigated. In fact, Mr. Reckenzaun perhaps did more than anyone to show, by his practical work, and by various papers, the value of storage batteries in all kinds of electrical work. He spent a year or so in America successfully fighting the fight of such batteries. More recently he has been closely allied with the General Electric Company and with Messrs. Greenwood and Batley. Mr. Reckenzaun reached his acknowledged position as one of our foremost experts in batteries and traction because of the painstaking industry and skill with which he investigates every problem connected therewith. Some months since, the lung troubles to which he finally succumbed were felt to be serious; but although then seriously ill, he during the late summer visited America, hoping the change would prove beneficial, as well as desirous of continuing those business relations which he had on that side

ANTHONY RECKENZAUN.

as well as on this side of the Atlantic. Unfortunately, the hoped-for improvement did not come, and on his return he gradually declined, though hopeful to almost the last. To most of us the loss of this prominent member of the industry means the loss of a personal friend whom we all esteemed, and who was as firm in his friendship as he was able and energetic in his occupation. As will be seen, Mr. Reckenzaun had been engaged in the industry from its rise in 1881, and throughout this period had made a reputation in his particular sphere second to none. His lectures on electric traction to the City Guilds formed the basis of a book on the subject, in which his great knowledge of the subject is fully shown. Yesterday his mortal remains were consigned to their last resting-place in the presence of numerous friends.

REVIEWS.

A Manual of Telephony. By W. H. PREECE, F.R.S., and A. J. STUBBS. Whittaker and Co., London.

This is practically a second edition of "The Telephone" by Preece and Maier, published in 1888, although in consequence of the change in the co-authorship it has been deemed desirable to issue the work as a new one. Mr. Stubbs is a well-known member of the Post Office technical staff, and in securing his collaboration Mr. Preece has been distinctly fortunate. Not only has the subject matter been more judiciously selected, but the book bears the impress

of careful editing, and lacks the numerous errors and bêtises which disfigured the old one and discounted its claim to acceptance as an authority on the telephone and its practical applications. The general plan, however, has not been changed nor has the scope been extended, nor the limits amplified. The alterations consist chiefly in the suppression of the long descriptions of German and French apparatus which constituted a feature of the older book, and which never possessed any value for the telephonist in this country, and the substitution therefor of minute explanations of the most recent improvements in switching apparatus. Thus, not only are the latest American plans, as represented by the Western Electric Company, minutely explained and liberally illustrated, but the switching apparatus designed by Mr. A. R. Bennett for the New Telephone Company, and which recently formed a subject of controversy in the electrotechnical Press, is for the first time described in print. An interesting feature of Mr. Bennett's system is the special form of induction coil used in subscribers' instruments for the purpose of ensuring a perfect balance in the metallic loop under all circumstances. Ordinarily it frequently happens that when two subscribers lift off their phones to speak, the two receivers are in one side of the loop and the secondaries of the induction coils in the other, the phones thus being placed between branches of unequal resistance. The perfect silence aimed at by the use of metallic circuits is lost under such conditions. In Mr. Bennett's coil the secondary is divided into two halves of equal resistance with the receiver connected between them, so securing a permanently perfect balance so far as the instrument is concerned. Mr. Preece, it is to be noted, sticks to his guns manfully on the subject of his K R law, and allows neither the papers of Oliver Heaviside nor the scepticism of many practical telephonists to prevail against him. The work is well and profusely illustrated, the cuts being for the most part prepared from special drawings. Altogether, the new book may be welcomed as the most complete epitome of present-day telephonic practice yet published.

Electric Lighting and Power Distribution. Part III. With 70 illustrations and index. By W. P. Maycock, M.I.E.E. Whittaker and Co.

This third part completes the book. The first portion of this part, though Chapter XII. of the book, discusses principally secondary batteries. A brief history of what may be termed electro chemistry is given, reference being made to Faraday, Grotthuss, Clausius, among the scientific investigators, and to Planté and his successors among those who applied the principles evolved by their predecessors. This information is not very important, but it is followed by an excellent description of a simple battery installation, the illustration to which is worth all the history put together. This is the kind of matter students want—it teaches something new to them, whereas history is everywhere. The next chapter deals with transformers, and describes the open and closed circuit and the continuous-current transformer. It is a pity that the illustration of the latter is so bad, for as a rule the illustrations are excellent. The various systems of distribution next claim attention, and here again the descriptions are simple and the illustrations excellent. Unfortunately, the author never seems to think of any other end than answering examination questions, and thus he deals too much with descriptions rather than with principles. Little real knowledge of the subject and no originality is required for such mere descriptive matter, and our author can do better if he likes; but these questions at the end of each chapter have hampered him. Still, the questions as given are of great use, only if the information enabled constructive questions rather than descriptive, they would be better. After a chapter on fuses, regulators, earthing devices, and similar things, we come to a chapter which will prove one of the most valuable to the student. This is a chapter of worked examples, and admits of what we term constructive questions. The value of such a chapter we will attempt to explain. When a student gets mere description, and has to take his place in actual work, he is unable to design under circumstances which differ considerably from those named in his books. Hence, a book intended for students should tackle principles as well as description in order that the reader may be able to apply those principles in practice. You cannot too often explain principles, nor should repetition be avoided if it will assist to drive home the principle under discussion. Hence, we are inclined to think that this one chapter will do more to aid the student than the remainder of this part. Of course, our remarks are somewhat out of place, in that the whole work has a special object, that of preparing for a certain examination, and thus the author is bound to consider the requirements of a syllabus. No matter how such a syllabus be drawn, it must hamper an author, and while he may produce an admirable book for the purpose intended, it might without such restriction be useful for a wider *clientèle*. Students of the City Guilds' examinations will no doubt make this their text-book, and will find it giving what they require; but we wish examinations of the cut-and-dried kind now fashionable were abolished, and leave teacher and author with greater freedom.

INSTITUTION OF ELECTRICAL ENGINEERS.

The first meeting of the autumn session of this Institution took place on the 9th inst., Mr. W. H. Preece, F.R.S., president, in the chair.

The **Secretary** (Mr. Webb) read the minutes of the previous meeting, which were confirmed, and the names of candidates for election and transfer. The following names were then mentioned of donors to the library:

Foreign Member.—Mr. Nikola Tesla.

Members.—Messrs. C. H. W. Biggs, A. Fahie, and Druitt Halpin, Profs. A. Jamieson and A. B. W. Kennedy, Mr. W. Perren Maycock, Prof. H. Robinson, Sir David Salomons, Messrs. J. N. Shoolbred, A. Siemens, and A. Campbell Swinton, and Sir Charles Todd.

Associates.—Messrs. C. E. Hawkins, L. Newitt, J. T. Niblett, J. Munro, and R. W. Weekes.

Non Members.—The Astronomer Royal, Mr. F. B. Behr, the Director General of Telegraphs (India), Messrs. C. Griffin and Co., M. E. Jacquay, Minister of Posts and Telegraphs (Rome), the Radcliffe Library (Oxford), and Mr. T. C. Webb.

Prof. George Forbes, F.R.S., then read the following paper on

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.

Table of Contents.—1. Introductory. 2. Relative Advantages of Direct and Alternating Currents. 3. Number of Phases. 4. Frequency of Alternations. 5. Electromotive Force. 6. Parallel Working. 7. Motors. 8. Line Construction. 9. Description of Machinery to be Used. 10. General Description of a 5,000-h.p. Alternator.

Introductory.

I had originally intended the title of this paper to be "The Transmission of Power by Electricity," but I found on writing it that it was inevitable that the work on which I am engaged as electrical consulting engineer at Niagara Falls should take a very prominent part in its substance, but the paper does still deal with the general question. On the 14th of December, 1892, I read before the Society of Arts a paper on "The Utilisation of Niagara Falls," in which the general plan of operations was described. But at that time the electrical developments were not sufficiently advanced to enable me to treat of that part of the subject. A reference to that paper will prevent the necessity of my wasting time in describing in detail the civil engineering and hydraulic arrangements. The object of the present paper is to put before this Institution the circumstances under which this great problem has been attacked, and the views which have been arrived at, and also to describe, so far as any work has been done, the electrical machinery to be installed.

The utilisation of the Falls of Niagara has long been a favourite theme of engineers, but it was not until the transfer of power by electricity became feasible, that this could enter very satisfactorily into the region of practical engineering. The matter is now in the hands of one of the most powerful combinations of New York capitalists which has ever been formed. Under their auspices the matter was, for the first time, thoroughly investigated from an engineering, financial, and commercial point of view. Rights were then acquired, and companies formed. The Cataract Construction Company does the engineering work, and will then hand it over to the Niagara Falls Power Company. The Land Development Company builds a whole village on the extensive lands acquired. The Niagara Junction Railway Company constructs six miles of terminal railway to connect all the factories, as they are built, with the railways in the neighbourhood. Rights of way are obtained in many directions, and also over the Erie Canal, which connects the Niagara and Hudson rivers. Allied companies are formed to develop power to all the cities within reach. Roads are made, leases of land granted, factories built, and the engineering works taken in hand by the Cataract Construction Company. It is with this latter that we have chiefly to deal. Mr. E. D. Adams is the president, Mr. F. L. Stetson the first vice-president, and Mr. E. A. Wickes second

vice-president, Mr. W. B. Rankine is secretary and treasurer, Mr. G. B. Burbank is the chief engineer, and Dr. Coleman Sellers acts both as consulting engineer to the Cataract Construction Company and president of the Niagara Falls Power Company, while undertaking at the same time many of the duties of resident engineer. The waters from the river are taken in at a point about a mile and a half above the Falls by a canal, from which it is led, by channels, into a long slot in the ground, going to a depth of 200ft. In this slot are iron pipes, or flumes, down which the water is carried to the turbines, and the waste water is carried through a tunnel for a distance of 7,000ft. to a point a few hundred yards below the American Falls, where it discharges into the lower river. Each turbine is of 5,000 h.p., revolves at a speed of 250 revolutions per minute, and is mounted on a vertical shaft. Above it there is a shaft extending in a vertical direction to the surface of the ground, on which a power house is built and the revolving part of the dynamo is placed directly upon the top of this shaft. The present paper may be divided into two distinct parts - first, the plans of working, of which, as their consulting electrical engineer, I have recommended the adoption; and, second, the design of the machinery which is to be used. In neither of these two parts can I claim to have done anything of great novelty or originality. I have simply collected together the results of experience which are available to all engineers, and in any advice that I have given I have simply followed the logical conclusions that were to be derived from the past experience; and in this I have been benefited by the courtesy and kind assistance of professional men, inventors, and manufacturers in both continents, who, almost without exception, have put their experiences at my disposal. If I have been the instrument to put before the company any designs of value, it has been to a great extent as the assembler of ideas which have originated as often in the minds of the engineers and draughtsmen who have given me their assistance, as in my own. I wish especially to express how much the company is indebted to Prof. Coleman Sellers, one of the most distinguished mechanical engineers in the United States, and who has assisted me throughout with his advice and suggestions, and who may be said to have originated the form of bearings and their supports which are to be used in the Niagara dynamos. I have also received valuable suggestions from my colleagues, Prof. Unwin and Colonel Turrettini, and also from the draughtsmen who have assisted me, and from numerous friends in our profession.* I have been desired by the president of the company to take this opportunity of stating some of the events which have culminated in the present satisfactory position of the company with regard to its contracts for machinery.

Relative Advantages of Direct and Alternating Currents.

A few years ago it would have been considered necessary to devote a considerable amount of space to the discussion of the relative merits of direct and alternating currents. During the last two years, however, opinions have advanced so steadily in the direction of preferring the alternating current for the transfer of power to any considerable distance, that it is not necessary to give much time to this question. One of the chief difficulties in connection with using the direct current is that it is necessary, for getting the best results, to connect a number of dynamos in series, and also to put the motors at the receiving end in series with each other. This involves the insulation of each dynamo and motor from the earth – a requirement which can in some cases be attained, but which in a general system of distribution is apt to be attended with difficulty, and perhaps with danger. The best case of the kind which has been put in practice is that of Genoa, and we gave it the most serious attention, but came to the conclusion that, for our purpose, it was undesirable. The facility which the stationary transformers used with the alternating current give for varying the pressure according to the requirements of economy or safety, is one great feature in favour of the alternating current. The question was considered in all its bearings with the utmost care, and it was not until the month of May, 1893, that the board of directors passed the resolution to adopt the alternating current, both for their distant transmission and also for the works nearer to the power house. It was proposed, indeed, by some manufacturers to distribute the current within a radius of a mile or two at 700 or 800 volts, and one firm proposed to do this by means of a direct current. Had this plan been accepted, we should have arrived at the surprising result that by using the continuous current at 700 volts within a mile or two, and high-pressure alternating current for more distant places, it would have cost more to produce a horse power per annum at Niagara Falls than at Buffalo.

The argument that seemed to me the most important in favour of using the direct current was, that motors for this purpose have been made in much larger quantities than alternators, and that it would be seldom necessary to build special types of machines to act as motor. This advantage seemed to be of great importance, until I realised the value of a low frequency used with the alternating current. So soon as we reduce the frequency low enough, we are able to alter a direct-current motor into a synchronising alternating motor, by the simple addition of a couple of rings placed on the commutator and electrically connected with opposite bars of the commutator, and a brush rubbing on each of these collecting rings. I also took into consideration the question of the possibility of storing up energy in storage batteries during the night time, when, of course, the demands on our plant would be least, and giving it off during the daytime; but at the present time the cost of the batteries would not repay work in this direction, and it would be cheaper to make another tunnel, with wheel pits, turbines, and all the paraphernalia required to generate current, than to go to the expense of putting down the large amount of lead which is required for these batteries. With the alternating current we have the choice of a considerable number of motors of different types. We have the synchronising motor, the series wound motor with laminated field and commutator, the multiphase motors, which attracted so much attention at the Frankfort Exhibition of 1891, and a host of single phase motors which have been developed by various inventors, but which have never been placed on the market because of the high frequency which has been prevalent, and with which they were not altogether satisfied. These motors become immediately available if we use a lower frequency. The generation of an alternating current also permits of the use of a commutator, or rectifier, with direct current motors.

Number of Phases.

Assuming now that it is generally agreed that the alternating current must be adopted not only for the distant transmission, but also for the nearer work, the next point to consider is the number of phases - whether the current should be generated in a single phase, in two phases, or in three phases. The possibility, too, of using even a greater number of phases was also considered, but it did not seem to possess advantages.

As already stated, there are many motors which are suitable for use with a single phase at low frequency, and which start without assistance. In the workshops of nearly all the most able electricians which I have visited in the course of the last year or two, I have found such motors built upon different plans, and nearly all of them seemed to work fairly well, and promise to be very efficient at low frequency.

For all heavy work which is going on constantly without stopping the machinery, no motor could be more suitable than the synchronising alternator on a single phase, and its speed is as regular as that of the turbine which is developing the power. It seems, however, that even if single-phase motors are going to be adopted, it would be best for the generator to have two phases, because in this way we get a larger output for the same size and price of machine, the circuits may be perfectly independent, and supply separate motors. Also the two-phase system makes the rectification or commutation of the current more easy to use it for street railways, electro-metallurgy, etc. Again, multiphase motors have a great advantage that they have been considerably utilised already, and even in small sizes have a fairly good efficiency.

With regard to the relative merits of two and three phases, several claims that cannot be supported have been put forward in favour of the latter. First, it is claimed that the saving in the copper on the line is 25 per cent. over a one-phase system, and 25 or 13 per cent. over a two-phase system, according as four or three wires are used for the purpose. I investigated this matter carefully, and arrived at the conclusion that this was not the case, and that the three-phase system had no advantage in this respect over a two-phase system with three wires. Second, it is claimed that there is a greater simplicity of wiring with three phases than with two phases; but this advantage disappears when we remember that the two-phase system can be used with only three wires, although this is not a plan which I would recommend. Third, it is claimed that any pair of the three wires may be used for a distribution of lighting. This is not the case. A two-phase system, where the circuits are completely independent, is much more suitable for the purpose, and maintains the lights at a more constant electric pressure. Fourth, it is claimed that there is a smoother starting and rotating effort with the three-phase than with the two-phase system. This was originally claimed on theoretical reasons only by Dobrowolski, but everyone who has used the type of two or three-phase motors made by the Oerlikon Company, by C. E. L. Brown, and by the Allgemeine Elektricitats Gesellschaft, of Berlin, and others, is convinced that this advantage, which seems probable enough, is purely theoretical; it is not confirmed by actual practice, and, moreover, when the fact is known, the theoretical reason is pretty evident.

No other claims in favour of the three-phase system over the two-phase have ever to my knowledge, been advanced; and, as shown above, a very full consideration of these claims does not tell in favour of the three-phase.

I will now point out what seemed to me great objections against the three phases, due to the fact that the three conductors are all inter-connected. First, it introduces trouble in maintaining the efficient working of the line, and in testing it, so that a higher type of electrician would be required to make these tests, and even he would have greater difficulty in finding the faults and correcting them. Secondly, when the three circuits are unequally loaded the electric pressure varies considerably. These difficulties have been thoroughly appreciated by workers in this line. When an inter-connected set of circuits such as the three-phase system employs is used, it is found that when the circuits are unequally loaded there are great variations in the electric pressure, and the following tests were made at my request to illustrate this. The three circuits are called A, B, and C. The average electric pressure of the three branches at the terminals of the secondaries was maintained constant. A resistance tending to reduce the electric pressure at the lamps 5·3 per cent. was introduced into each branch. Both the primaries and the secondaries were connected as represented by the form of the letter Y. By varying

* I must mention the names of the following draughtsmen who have worked on the dynamo designs for me. In England, Mr. F. M. Weymouth was chief draughtsman, assisted by Messrs. A. Wilson, R. H. Simpson, G. E. Groom, F. Wilby, W. L. Hamilton, W. M. Williams, and W. H. Hudson. In America, Mr. Baumann was chief draughtsman, assisted by Messrs. Steen and Jacobsen; Mr. Vogel also worked for me there.

the connections in different ways, some slight variations were possible; but this general fact remained, that when A is loaded and B and C are not loaded, the pressure of A is less than that of C, and that of C is less than that of B, and the difference may be 12 or 13 per cent.; and when A and B are loaded and C is not loaded, the pressure of A is less than that of B, and that of B is less than that of C. The variations here shown in the pressure of two equally loaded circuits is probably due to the armature reactions, and would be found in a two phase system also; but the rest of the variation is due to the inter connection of the three circuits, and is an obvious defect of the three phase system. In order to get over this difficulty, the Oerlikon Company proposed to devote only one circuit to lighting purposes, which shall be maintained at constant pressure, using the other two circuits for power purposes, where constancy of pressure is not so important. In some cases this would be a suitable method of working, but it was not considered satisfactory for the work at Niagara Falls. Having considered these points, the board of directors of the Cataract Construction Company at their meeting in May, 1893, determined to reject the three phase system, leaving the single-phase and the two-phase available.

Conditions.	Volts at terminals of lamp mains.				Difference between maximum and minimum volts.
	A.	B.	C.	Average.

Frequency of Alternations

I wish now to say some words on a question which has absorbed my most serious attention, especially since I have been acting for the Cataract Construction Company, and this relates to the frequency of the alternating current. In America a frequency has generally been adopted of 133 complete periods per second for lighting purposes. This was done with the object of reducing the cost of transformers, which were supplied to each separate house, and consequently were always of small size, and therefore expensive. The selection was also approved because American engineers working with alternating currents have generally put forward the view that parallel work is not desirable, and the fact that parallel working is more difficult at high frequency, which is one of the principal objections to high frequency, has not been seriously considered in America. In Europe the usual frequencies are from 70 to 100 periods per second, but a notable exception exists in the case of Messrs. Ganz and Co., of Budapest, who have adopted 42 periods per second. Some years ago I unwittingly did Messrs. Ganz the injustice to say that I thought it probable that they had adopted this frequency because it suited their particular type of machinery and speed of running. I have it in writing from them, and I am thoroughly convinced of the truth of it, that their reason in adopting the frequency of 42 periods per second was that it is the lowest frequency that is available with arc lights so as not to produce any serious flickering, and their desire was to lower the frequency as far as practicable in order to ensure parallel working. Of course, it is a matter of common knowledge that parallel working is assisted by lowering the frequency.

With the large units which will be employed in connection with the Niagara Falls scheme, the cost of the transformers is very much diminished; and this does not become so important a matter as it does when all the transformers are of small size — under 10 h.p., as is usual in electric lighting in America. Moreover, although with lower frequency the transformers must be increased in size, the increased cost is not in proportion to the lowering in frequency, because we can use a higher induction. Mr. Steinmetz has shown that the loss due to hysteresis varies as the induction raised to the power 1·6, and it is this loss which must be kept constant when we vary the frequency. I deduce from this law the fact that in any transformer, if the hysteresis loss is kept constant, its power of doing work varies in proportion to the frequency raised to the power 0·4 (but it is probably unwise to increase the induction so much as to saturate the iron). It follows that when we double the frequency we get out of the same transformer 132 units of work instead of 100. If the frequency were quadrupled, we should get 174 units instead of 100. I have been informed by Mr. William Stanley, jun., of Pittsfield, Mass., that without the use of theory, but simply working from his experience in manufacturing and testing transformers, he obtains almost identically the same law; and I have got independent practical testimony in the same direction from other manufacturers. It appears, then, that there can be no doubt that in lowering the *frequency we are not proportionately increasing the cost; but at the same time it must be realised* that the cost of transformers is to a certain extent increased by lowering the frequency. If the frequency be reduced to one half, the cost is increased about 50 per cent. The lowest price which has been quoted for large transformers is 3·52dol. per horse power, at a frequency of 42 periods per second. In halving the frequency the extra cost would therefore only be 1·76dol. per horse-power. It becomes, then, a matter of enquiry whether the benefits to be derived by lowering the frequency in such a proportion would compensate for the extra expenditure as indicated. I am thoroughly convinced that the gain is far in excess of this amount. I shall have occasion to discuss the superior efficiency of motors at low frequency; and in most types of motors I think it safe to say that in passing from 42 periods to 21 periods, or varying the frequency in that proportion, we have a gain of at least 3 per cent. in the efficiency of the motors. Neglecting altogether the increased value of the motors from this cause, there is 3 per cent. more power at our disposal, which, at only 10dol. per horse power per annum, would amount to 30 cents per annum, or, capitalised at 5 per cent., represents an increased value of 6dol. per horse-power of the plant, against which we have the increased cost of transformers — only 1·76dol. It appears, then, pretty certain that, from a purely economical consideration of the question, a lower frequency than any which has hitherto been adopted is advantageous.

With regard to the lowest limits at which we can work, since our turbines have been designed to revolve at 250 revolutions per minute, a two poled dynamo — if such could be satisfactorily constructed — would give a frequency of 4⅙ periods per second, and none of the synchronising or polyphase motors employed at different factories could run at a higher speed than 250 revolutions. I am not sure that it is desirable that any motors should run at a higher speed than this, but in the few cases where this might be desirable the use of belts would be quite natural in order to give the higher speed. With a four-poled machine we would have a choice of speeds at 500 revolutions, 250 revolutions, and any sub-multiple of these speeds; for by increasing the number of poles in the motor the speed of the motor can be reduced as much as we please. With eight poles in the generator, the maximum speed is 1,000 revolutions per minute, which is as high a speed as would generally be desired in connection with the factories supplied from Niagara Falls. This frequency is 16⅔ periods per second, and after considering the three points — namely cost of transformers, speed of synchronising motors, and convenience in the design of the generators — I came to the conclusion that, so far as motive power was concerned, this is the frequency which would be most favourable for use at Niagara Falls.

Another indirect advantage of using a low frequency is of a very practical nature, and lies in the fact that the ordinary continuous current dynamos of any size that are made may be used as synchronising motors by means of rings attached to the commutator bars in the manner which has been above described. This method of altering and working a direct-current motor so as to make it suitable for an alternating current of low frequency has long been known to electricians, but the attention of those who are not experts was forcibly directed to it by the machines shown by Mr. Schuckert and others at the Frankfort Exhibition in 1891. Owing to this fact, it would be possible for any manufacturer connected with our supply station to procure a motor of low frequency of any moderate power he might require at a day's notice, and this is not true of any other alternating motor, nor is it true of a higher frequency.

But the most obvious advantage of low frequency is the improved efficiency of motors. I have arrived at this conclusion from my own observations, but I find it confirmed collaterally. With synchronising motors, of course, the fact has long been thoroughly established that the performance is very much improved by using low frequencies. Again, those who have used the motors with rotating field of the two phase or three phase type have all been obliged to reduce the frequency of the current to get the best results. In this connection I am pleased to be able to show a diagram giving some tests which were made for me of a three-phase motor at 41 complete periods per second, and at 56 periods per second.

It will be noticed that at 56 periods the maximum efficiency is given when the output is 17 h.p. It is then 85 per cent., and the efficiency at 41 periods per second at the same output is 87 per cent. But it will be noticed that the efficiency at the latter frequency goes on increasing until the output of the machine is 19½ h.p., when the efficiency rises to nearly 88 per cent. Thus, by lowering the frequency from 56 to 41 periods per second, not only had the output of the motor been increased 15 per cent., but the efficiency had also been increased 3 per cent. It is also found — which is a matter of the utmost importance — that in every self starting alternating motor, whether multiphase or otherwise, the effort at starting is increased by lowering the frequency.

Again, I find that the ordinary direct-current motor with a laminated field works extremely well with low frequency; even without lamination of the field it works, though not well. I have consulted nearly every electrician of experience in this direction whom I have met during the last year or two, either in Europe or America, on this point, and they generally agree with me that the facilities of working motors of whatever kind are very much greater with a low frequency. Last year, being aware that Prof. Anthony had experimented considerably in the direction of series wound motors with laminated field, I asked him his opinion, and he expressed himself as follows:

"In reply to yours of August 30, I have built two or three continuous current machines with laminated fields to run with alter-

nating currents, and have succeeded in running motors of about ½ h.p. directly from the Westinghouse converter, where the frequency is some 130 per second. Such small machines run very nicely where the alternations do not exceed 25 per second. In fact, so far as I have tested, they seem to give an output fully equal to what they will with continuous currents. Of course, with high frequencies the self-induction of the field is against their working, but at eight per second I should say that large motors could be run with perfect success."

I wish to repeat that, from what I have seen in the workshops of all advanced electricians in the last year or two, I am confident that in the near future single-phase alternating current motors, self-starting on full load, will be largely used; and there is not the slightest doubt that all of these work far better with low frequencies. In fact, as Mr. Brush once said to me when I was discussing this matter with him, "Really, your best plan would be to lower the frequency so much that you get a direct current."

Whilst speaking of low frequency in relation to motors, I must say that I have much greater hopes of obtaining a good commutating device with a low frequency than with a high one; and I will also state that I have great hopes of important advantages coming to us from the invention of such a commutating appliance which will enable us to furnish street-railway companies, electro-metallurgical works, and other consumers with the direct current without the use of any heavy revolving machinery at the transforming station.

I am not sure that it ought not to be said that the greatest advantage of low frequency is in connection with the conductors used for transmission, and in the parts of the apparatus that require high insulation. When a high frequency is used there are certain difficulties which are well known. The first of these has been strongly urged by Lord Kelvin—namely, that when using large conductors an alternating current of high frequency tends to confine itself to the outside of the conductor, thus increasing the total resistance. Attention was first generally directed to this subject by the presidential address of Prof. Hughes to this Institution. A second difficulty is that with high frequency the impedance of the line due to the magnetic field formed between the go and return wires may amount to a very sensible quantity. Attention has been drawn to these matters by Mr. A. E. Kennelly, and his paper* on the subject should be carefully studied. Then, again, with high frequency there is a greater tendency to discharge from an electrified conductor into the air. This means that the insulating of a bare conductor is more difficult with a high than with a low frequency. Lodge and others have made this very manifest with exceptionally high frequencies, but the truth of the statement is well known by those who have experimented even with low frequencies. Another trouble is that, whenever it is necessary to use solid insulation, a current of high frequency has a greater tendency to injure the insulation. Mr. Tesla has shown and explained so clearly the rapid deterioration of solid insulation by currents of enormously high frequency, that we cannot fail to see that advantage is gained by using currents of low frequency. Another very important fact is that with low frequency we are less troubled by the capacity of cables, and we have less loss of static charge accompanied by heating of the insulation. Again, the serious troubles which have been encountered at Deptford and elsewhere owing to abnormal rises of electric pressure in the mains above the pressure generated by the dynamos, due to the resonant effect produced by the capacity of the cable and the self-induction of the circuit, may be reduced as much as we please by sufficiently lowering the frequency. All these facts are the explanation of what has been thoroughly established in actual practice—namely, that there are difficulties on the line when using high frequencies which tend to loss of power and to destruction of the insulation, and that these difficulties are largely mitigated, if not entirely obviated, by reduction of the frequency. It must also be remembered that if we reach a frequency as low as 16 periods per second, any induction in neighbouring telephone circuits is utterly inappreciable by the ear. Finally, all eddy currents diminish as the square of the frequency. Having now stated as clearly as I can what seemed to me the principal advantages of low frequency, I will place on the other side the disadvantages.

Besides the increased cost of transformers, there is one fact which is apt at first sight to impress one as almost fatal to the employment of very low frequency, but which further consideration shows to be of little moment in the case of Niagara Falls—this is, that a low frequency is not suitable for electric lighting directly. But it must be remembered that it is decidedly preferable to use a direct current for arc lamps, and, in fact, in the present position of the art in America it would be almost a necessity. Hence the natural method of arc lighting would be to use the alternating current by means of a motor to drive the well-known arc lighting machines. In the course of the work at Niagara, the first work in connection with arc lighting which will be set up is the lighting of Buffalo. At present this is done by means of steam engines, developing about 3,000 h.p., and driving arc lighting machines of the Brush, Thomson-Houston, and Wood types. There cannot be a doubt that, financially and practically, the best way of converting this station to enable them to use the power from Niagara Falls is to put in alternating motors in the place of the steam engines, and this will be the case in most of the towns which will be supplied with power from Niagara Falls.

(To be continued.)

* "Impedance," by A. E. Kennelly, American Institute of Electrical Engineers, April 18th, 1893.

PHYSICAL SOCIETY, Nov. 10, 1893.

Prof. A. W. Rucker, M.A., F.R.S., president, in the chair.

Mr. R. S. Cole was elected a member of the society.

A paper "**On the Separation of Three Liquids by Fractional Distillation**," by **Prof. F. R. Barrell, M.A., B.Sc.; G. L. Thomas, B.Sc.; and Prof. Sydney Young, D.Sc., F.R.S.** was read by Prof. Young. Accepting the results obtained by F. D. Brown in his experiments on the variation in the composition of the distillate from a mixture of two liquids—viz., that the relative quantities of the two substances in the vapour at any instant are proportional to the weights of the substances in the still multiplied by the ratio of their vapour pressures—the authors write Brown's equation in the form $\frac{d\xi}{d\eta} = c\frac{\xi}{\eta}$, where ξ and η are the weights of the two liquids in the still, and c the ratio of their vapour pressures. Taking c as constant, the above equation is integrated, and from the resulting expressions curves are plotted showing the changes in composition that take place during the distillation. Assuming that a similar law holds for three liquids, A, B, and C—viz., $\frac{1}{a}\frac{d\xi}{\xi} = \frac{1}{b}\frac{d\eta}{\eta} = \frac{1}{c}\frac{d\zeta}{\zeta}$, the composition of the distillate at any instant is calculated. Taking $a = 4$, $b = 2$, and $c = 1$ (numbers nearly proportional to the vapour pressures of methyl, ethyl, and propyl acetates), numerous curves are plotted, showing the progress of the separation at various stages of fractionation. These curves show distinctly that although fractions containing large proportions of the liquids A and C, of lowest and highest boiling points respectively, can be easily separated, the middle substance, B, is much more difficult to obtain in a state of purity. Consideration of these curves led the authors to see that by carrying out the fractionations in a particular way, it was possible to separate the mixture into two portions—one containing only A and B, and the other B and C. These mixtures of two liquids could then be fractionated in the usual manner. This process was carried out on a mixture of methyl, ethyl, and propyl acetates the results of which are given in considerable detail in the paper. The remarkable agreement between the densities of the ethyl acetates obtained respectively from the mixtures (A and B) and (B and C), as well as the fact that the densities of the separated liquids were the same as before the mixing, show conclusively that the method employed was highly successful. **Prof. Ramsay** said the paper was a most valuable one, and would be a great aid to chemists. Distillations were usually carried out by mere "rule of thumb," with the result that absolutely pure liquids could rarely be obtained. The **President** enquired whether curves representing the progress of distillation could be constructed from the very complete experiments made, and so test the assumed law. **Prof. Young** thought this not possible from the numbers obtained. To test the law in this way would be very laborious.

A "**Note on the Generalisations of Van der Waals's Regarding 'Corresponding' Temperatures, Pressures, and Volumes,**" was read by **Prof. S. Young.** In November, 1891, the author read a paper on the same subject (*Philosophical Magazine*, February, 1892), and gave the critical molecular volumes of some 12 substances as calculated by M. Mathias. Since then, a few small errors have been found in the calculation, and the author's corrected values are now given. The vapour pressures, molecular volumes, and critical constants of 10 esters (methyl formate, acetate, propionate, butyrate, and isobutyrate; ethyl formate, acetate, and propionate; and propyl formate and acetate) have recently been determined (*Transactions* Chemical Society, vol. lxiii., page 1,191). In the present paper the absolute temperature and volumes of the 12 substances are given in terms of their critical constants, and tables given showing respectively the ratio of boiling points (abs. temps.) at corresponding pressures to absolute critical temperatures, the ratios of volumes of liquid at corresponding pressures to the critical volumes, and ratios of volumes of saturated vapour at corresponding pressures to critical volumes, for the halogen derivatives of benzene, benzene, carbon tetrachloride, stannic chloride, ether; methyl, ethyl and propyl alcohols, and acetic acid; and the extreme values for the 10 esters previously mentioned. Whilst showing fair agreement with each other, the differences between them exceed errors of experiment. The ratios also indicate that the substances can be arranged in four groups, thus tending to show that molecular weight and chemical constitution have some influence on the results. The differences found would probably result from the presence of complex molecules such as are known to exist in acetic acid. If Van der Waals's generalisations were strictly true, the ratios $\frac{PV}{T}$ at the critical point should be constant for all substances, as also the ratio, $\frac{D}{D'}$, of the actual to the theoretical density (for a perfect gas) at the critical point. On comparing these quantities, only a rough approximation is found, but the grouping of the compounds is again well marked. **Prof. Ramsay** was not sure that the existence of complexes would alter the molecular volume in the liquid state, for liquids seem very compact. Experiments on the surface energy of liquids had proved that complex molecules do exist in the alcohols and acetic acid. Dr. Young's conclusions were therefore confirmed by experiments of an entirely different nature. **Prof. Herschel** was gratified to see Van der Waals's theory so well borne out in liquids, and hoped to see it extended to solids. The recent researches of Prof. Roberts-Austen on alloys seemed to point in this direction. **Mr. Rogers** said molecular complexes, &c.

exert an influence on the properties of substance as had been shown by Prof. Thorpe's viscosity experiments Van der Waals's generalisations should, therefore, be looked at from a chemical as well as a physical point of view. The **President** thought the numbers brought forward showed fair agreement, especially when it was remembered that Van der Waals took no account of complex molecules Contrary to Prof Ramsay, he would rather expect aggregation to affect the molecular volumes in the liquid state, for only about one-fifth the space was supposed to be occupied by matter On the other hand, the relatively small contraction of liquids on cooling did not support this view

"**An Instrument for Drawing Conic Sections**" was exhibited and described by **Mr J. Gillott, B.A.** This consists of a spindle inclined to a plane board, and a tube fixed to the spindle at an angle A pencil, which passes through the tube, traces out a cone in space as the spindle is turned, and on sliding the pencil through the tube so as to keep its point against the plane, the point traces out a conic, the section of the cone made by the plane of the board. A circle, ellipse parabola, or hyperbola can be drawn according to the inclination of the spindle to the board **Prof Henrici** said a similar instrument had been described in an Arabian manuscript 1,000 years old, and had been independently reinvented by both a German and an Italian mathematician. He thought the fact of the angle between the spindle and the tube in Mr Gillott's instrument not being adjustable, was a disadvantage **Mr Inwards** and **Prof Herschel** also took part in the discussion, to which **Mr Gillott** replied

ELECTRIC LIGHTING AT KENSINGTON.

We have before referred to the report of Major General Webber and Mr Philip Monson to the Electric Light Committee of the Kensington Vestry, but we think that a portion, at any rate, of this report is of considerable interest to many local authorities who have to deal with the getting rid of house refuse as well as lighting questions. At the present time Kensington has to pay a large sum to get rid of certain refuse, hence in a report of this kind the question was certain to arise whether the destruction of refuse and the production of light could not be carried on at the same time The report states that in the district there are probably by this time nearly one hundred thousand 8 c.p. lamps connected with the four generating stations The companies in the district have capital invested to over three hundred thousand pounds. The report considers, first, the advisability and practicability from an economic point of view of consuming the refuse of the parish to produce electrical energy. To obtain information upon this point the destructor furnaces at Kidacre-street, Leeds, were visited, which furnaces deal with about 25,000 tons of refuse per annum, working three shifts a day, each of eight hours The authors have adopted "the reports of the use of refuse at Birmingham for producing steam namely, that in practice 1lb of refuse will evaporate 1·79lb of water the 25,000 tons of refuse at Leeds should be able to evaporate 44,750 tons of water, working six days a week, which at 25lb per indicated horse power, gives in 7,488 hours 530 h.p at one time thus quite confirming the superintendent's statements as to the practical calorific value of the Leeds refuse This result is obtained under unfavourable conditions, as the flues, owing to the previous existence of the chimney stack, are not designed as favourably for the utilisation of the draught, etc, as they might otherwise have been, and as the refuse consumed contains quite one-sixteenth more market refuse than the average from houses such as those in Kensington"

The second point considered was as to the advisability and practicability from an economical point of view of utilising any, and if so, which of the Vestry's wharves or depots for the erection of generating stations or other works.

The following estimate is given on this point: Our estimate of the outlay required for the destructors, with the land and buildings, but exclusive of the electrical generating equipment and boilers, is as follows:

Destructor house, with 12 destructors complete, with forced draught, flues, by-pass, etc., including cost of cofferdam to exclude canal water, etc.	£6,000	
Shop	230	
Chimney shaft	750	
Freehold value of site	1,700	
		£8 610
Boiler roof and flues	700	
Electric light station buildings	2,100	
		2,800
		£11,480

If electric light is excluded entirely and the site is occupied by what is required for destruction of refuse only, this figure will be reduced to £8,680

If it is used for an ordinary electric light station without any means of destruction of refuse, this figure would be reduced to £5 380

If either of the two alternatives was adopted the site would afford space for an extension of plant; but if the two processes are combined, the whole site is fully taken up at once, as described in paragraph 16.

Thirdly, "As to the advantages which it is suggested or can be shown would accrue to the consumers and ratepayers generally by Vestry undertaking the supply of electricity for public and private *purposes throughout* the whole or any part of the parish"

As already stated, we believe we are right in regarding the question of the Vestry becoming undertakers for the supply of electricity in competition with the existing supply companies within the areas allotted to them as one which is not at present ripe for consideration, as it opens up questions of demand, supply, and profitable expenditure of capital of a very complicated nature.

It seems desirable at this stage of our report to remind the Vestry that in the last five years the distribution of electrical energy both for light and power, in towns all over the world, has reached a position of practical application as an industry, not only as a public necessity, but also as a remunerative investment not far behind that which has been attained by its elder sisters namely, the supplying of gas and water In other words, that it is well advanced into its period of adolescence, and that all the conditions which are required to make it pay are thoroughly understood.

The anticipations during the early history of electric lighting in this country as to its general adoption have been disappointed because of their exaggeration: but estimates made 10 years ago of the probable demand in residential districts of London, based on one private house in three using the light within five years of starting to supply current, have been more than fulfilled There are reasons why such an estimate based on one house in four as regards the district with which it is proposed to deal should not be again excessive, in spite of the fact that in the latter the average ratable value of the property is much below that of other parts of Kensington

They are as follows: (a) It is found that the wiring of existing houses for the electric light is not often done except when the occupation changes. The owner has less inducement to wire his houses when once they are let, and the tenant, for a term, will rarely incur the outlay on a house not his own. Shorter tenure of occupation entailing more frequent changes of occupiers, which is the case in the less wealthy districts, should therefore give more frequently need and opportunity to carry out wiring (b) Wiring and fittings are costing 50 per cent. less than they did five years ago. This applies especially to fittings. For instance, a good 20-light distribution board can be now procured for about 18s. instead of former prices varying between £2 and £5. (c) Excellent energy meters satisfactory to the Board of Trade will soon be sold for less than 30s (d) Incandescent lamps will shortly be sold for 1s 3d. now, and be repairable for 6d. each, and there can be no doubt that a greater efficiency of the filament will ere long be provided, so that the same light will be yielded with a less consumption of current than now. If, in addition, the Vestry can, without incurring a loss sell current for 5½d. a Board of Trade unit, which is equivalent to 16 candle gas at 3s. 1d. per 1 000 cubic feet in the ordinary burners, the conditions for bringing this illuminant within the reach of all who now use gas are obtained, and the consumers will reap besides all the advantages to health and comfort, economy and safety recognised as accompanying the use of electricity.

As against the above inducements to an extension of the use of electric light into such districts based on the usual condition, which naturally influences an electric light supply company—namely, that it is an illuminant only accessible to the wealthy—we have compiled the following tables, which divide the custom between private houses and shops, and which also subdivide the same in groups according to rating, so that the proportion of each kind in each electric light district may be seen at a glance These figures show clearly the preponderance of the number of houses and shops at the lower ratings in Districts 1 and 2 as compared with the others.

TABLE showing the Decimal Proportion to the Whole Number in Groups according to Rating in each District.

Private Houses.

Districts.	£50.	£100.	£150.	£240.	Over £250.
1 and 2	·565	·331	·129	·032	·010
3	·101	·201	·283	·206	·165
4 and 5	·039	·110	·170	·337	·466
6	·295	·358	·418	·425	·359
	1·000	1·000	1·000	1·000	1·000

Shops.

Districts.	£50.	£100.	£150.	£240.	Over £250.
1 and 2	·621	·381	·178	·078	·087
3	·176	·258	·219	·174	·110
4 and 5	·056	·149	·294	·428	·593
6	·147	·219	·309	·320	·210
	1·000	1·000	1·000	1·000	1·000

The areas under consideration are shown by the map which is attached to this report, and include about three-elevenths of the parish, and lie to the north of Uxbridge-road, Ladbroke-grove, and Archer-street. Their length together is approximately 1½ miles from north to south, and 8½ furlongs from east and west. The following streets and portions of streets that we have selected and propose should be dealt with first are coloured on the map, and are selected as those in which a demand under the conditions we have mentioned may be fairly expected: Bassett-road, Blenheim-crescent, Cambridge-gardens, Colville-square, Colville-terrace, Clarendon-road, Elgin-crescent, Ladbroke-gardens, Ladbroke-grove-road, Ladbroke-grove, Lancaster-road (part of),

Lansdowne-road, Lansdowne-crescent, Norland-square, Oxford-gardens, Portobello road (part of), Powis square, Royal crescent, St. Charles-square, St. Mark's-road, Uxbridge-road. The total length of street in which mains should be laid along both sides is about 4·6 miles, and along one side only is about 1·4 miles. Total, about six miles of street.

In the following list of totals the shops and private houses in those streets are again distinguished and grouped, and under an estimate of the number of lights each might be expected to require a possible total of 40,390 8 c.p. incandescent lamps that may be eventually installed, is obtained:

Houses.

204 under	£50 rating, each	10 lights	....	2,040	
773 ,,	£100 ,, ,,	20 ,,	....	15,460	
289 ,,	£150 ,, ,,	35 ,,	....	10,115	
38 ,,	£250 ,, ,,	60 ,,	....	2,280	
6 over	£250 ,, ,,	100 ,,	....	600	
					30,495

Shops.

25 under	£50 rating, each	15 lights	....	375	
117 ,,	£100 ,, ,,	30 ,,	....	3,510	
59 ,,	£150 ,, ,,	50 ,,	....	2,950	
14 ,,	£250 ,, ,,	90 ,,	....	1,260	
12 over	£250 ,, ,,	150 ,,	....	1,800	
					9,895
	Total		....		40,390

The analysis of the above from metropolitan and other experience and results, and in view of the increased opportunities and inducements we have mentioned, permit an estimate of the probable number of lights that will be joined up during the first three years at:

One-fourth of 30,496 = 7,623
One third of 9,895 = 3,298

10,921

Of these we calculate that in houses $\frac{5}{7}$ths = 5,445, and in shops $\frac{6}{7}$ths = 2,826, will be in use at one time, giving a total for which plant should be provided of = 8,271.

These figures indicate that the minimum capacity of the installation to be put in hand for the supply of private lighting should be for 8,500 8-c.p. lamps in use at one time, which at 33 watts per lamp at the terminals, and 35 at the station, requires a plant that without spares should have a capacity of output of 300 kilowatts.

For public lighting of main thoroughfares two routes are plainly indicated as capable in the first instance of being supplied from a station at Kensal Wharf—namely, first, Ladbroke grove and Ladbroke grove road, lying north and south, and second, the Uxbridge-road from Norland road on the west to Kensington Gardens on the east—the united length of thoroughfare being about 2¼ miles. As regards this service of public lighting, if the Vestry desires to undertake it, and on economical grounds there are good reasons why they should do so, there are no difficulties and it can be done in conjunction with the private supply in Districts 1 and 2, and independent of the private lighting in part of District No. 3 now served by the Notting Hill Electric Light Company. This 2¼ miles, assuming that arc lamps giving the same light as those used in the City of London, are employed, and that these are placed at an average of about 70 yards apart, or 25 to the mile, will require about 63 kilowatts, raising the total capacity of the station to be first equipped to 363 kilowatts without spares.

Including spares, therefore, we are of opinion that the equipment of the station available for distribution should not be less than 500 e.h.p.

In estimating the cost of an installation system of the above-named size, it is usual to name a figure per electrical horse power which will cover everything, and in this case we estimate that figure at £75, which, for 500 e.h.p. gives £37,500. Following the same system, and taking into consideration the extended area over which supply has to be given, this total divides itself as follows:

22 per cent. for land and buildings	£8,250
30 per cent. for the equipment of the station	11,250
40 per cent. for the work in the streets	15,000
8 per cent. for contingencies (including provision to cover losses while first running the supply, say, for one year).	3,000
	£37,500

But in this case the item for land and buildings may be reduced, and it would be safe, owing to the fact that the fuel and stoking will not be a charge on the electric generation, also to reduce the estimate of contingencies by £1,000.

Our estimates under the circumstances may then be taken as follows:

Destructor, land, chimney, etc.	£8,680
Electric light buildings, etc	2,800
Equipment of the electric light station, including boilers.	11,250
Distribution, etc.	15,000
Contingencies	2,000
	£39,730

of which £31,050 is required for electric light.

This expenditure on electric light may be allotted in the following proportions to public and private lighting—viz.:

One-sixth to public = £5,175
Five-sixths to private = 25,875

Total £31,050

The annual charges on the debtor and creditor sides for the electric lighting alone, without combining it with the destruction of refuse, are as follows:

Debtor.

Interest and redemption at 4½ per cent. on £31,000	£1,395
Works cost at 2·95d. on 253,024 units, made for public and private lighting	3,110
Office and management and collection	500
Depreciation	832
Attendance and trimming 63 arc lamps	300
	£6,137

Creditor.

Value of 133,224 units, 12 units to each private lamp and 24 units to each shop lamp per annum nearly 8¼d. a unit	£4,577
Value of 63 arc lamps (nominal 2,000 c.p.) at £20	1,260
Public gas lamps discontinued	300
	£6,137

showing that if sold at cost price to the Vestry, 8¼d. a unit would have to be charged for the electricity.

The following is a similar statement for the destruction of refuse alone:

Debtor.

3½ per cent. on £8,680 cost of destructor	£390
Depreciation and repairs 3½ per cent.	304
Superintendence working, £20 a week	1,040
Clinker, ashes, etc., remaining on 25,000 tons of refuse, 8,250 tons, including lifting, 3s.	1,237
	£2,971
Saving	570
	£3,541

Creditor.

Barging at present rates 25,000 tons at 2s. 10d. from Kensal Wharf.	3,541
	£3,541

Lastly, follows a statement showing that the price at which the Vestry could sell electricity if the two are combined might even be as low as 4½d. per Board of Trade unit.

Debtor.

Interest and redemption on (£31,000—£8,680) £39,680 at 4½ per cent.	£1,785
Depreciation £832 + £304	1,136
Superintendence and working of destructors, boilers, and plant	1,040
Electrical works cost, less coal and stoking, at 1·48d. per unit made	1,556
Office management and collection	500
Removal and lifting remains of refuse	1,237
Trimming and attendance arc lamps	300
	£7,554

Creditor.

Saving on barging	£3,541
Public lighting	1,260
Private light, at about 4½d. per unit.	2,453
Public gas lamps discontinued	300
	£7,554

The above shows that if the Vestry sells electricity at 5½d. a unit to private consumers, as soon as the station is nearly fully occupied, there could be made a profit in favour of the ratepayers of about £550 a year. We have been careful in the above estimates not to minimise the charges on the debtor side, and it is clear that when the demand for current justifies an increase of the generating plant, the results will be very much better.

As regards the questions which the committee require us to answer, we believe that the above results fully justify us in giving an affirmative to each, and also in recommending the Vestry to proceed without delay for powers under a provisional order to deal with the whole parish: after which it will be time enough to give instructions for the detailed plans, estimates, and specifications to be put in hand. For reasons already mentioned, we should suggest that except for public lighting, and where the existing companies fail to give a supply, the Vestry may let the Board of Trade understand that for the present they propose to confine their operations to Districts 1 and 2.

In conclusion, we wish again to point out that the figures we have given show that any report which dealt with the question of the supply of the whole parish in a manner adequate to the future maximum demand, means that an expenditure of over half a million would have to be considered, and that then the annual economy on the working due to the use of house refuse as a fuel for generating steam, would affect but a small fraction of the total running costs. Such a report might have besides to deal with questions connected with the acquisition by purchase of the undertakings of the existing electric light companies, whether that acquisition took place at an early date, or was deferred to the end of the statutory period of 42 years. Throughout the provinces the local authorities are everywhere becoming the undertakers under the Electric Lighting Acts, and there are already examples of it in the Metropolis. The commercial considerations must be weighed equally whether the supply is by a private or public body, and it requires the lapse of some little time longer to show whether the latter can deal successfully with the question, apart from the exceptional advantages afforded, as in the case presented by this report, through the utilisation of the house refuse.

COMPANIES' MEETINGS.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

The statutory meeting of this Company was held yesterday at the Cannon street Hotel under the presidency of Sir Daniel Cooper, Bart., chairman of the Company.

The **Chairman** stated that the meeting had been called in compliance with the provisions of the Limited Liability Acts, and that they had no formal business to submit. He was happy to inform them that the reconstruction of the old company into the new had been carried out with complete success. They had applied to the Stock Exchange for a quotation for the new shares, and as they had supplied the committee with full and, he believed, satisfactory information on all points, they hoped that the quotation might soon be granted. They had succeeded in re-establishing the credit of the Company, and were in consequence able to do business on more advantageous terms than was possible in recent years. They had, therefore, every reason to expect that they would be able next autumn to submit a satisfactory report of the year's transactions. Since their last meeting the Board had been strengthened by the addition of Mr Philip E. Beachcroft, who represented the trustees of the first mortgage debentures, and also large holders of shares. He then called upon the Managing Director to address them.

Mr E. Garcke said that it was unnecessary for him to take up much time, as it was only four months ago that he made a full statement of the affairs of the Company. When he addressed them as shareholders of the old company on the 5th July, he explained in some detail the financial position of the Company and gave a description of the various assets. He mentioned on that occasion that there was much to be done before they could be in a thoroughly sound commercial and financial position, and that many of their investments were of such a character that if properly developed, promised not only to become more valuable, but also have the effect of largely increasing the business of the Company. He had also remarked prior to the reconstruction that the Company was suffering both in name and in credit, that they had difficulties in competing fairly with others, and that they did not get the full benefit of what they were doing. He likewise explained that if the reconstruction was carried, the prospects in these respects might be expected to improve. He then proceeded to indicate how far those anticipations had been realised in the four months that had elapsed. The financial position, he observed, had greatly improved. They had taken steps to realise some of the securities in which so much money was locked up, and the credit of the Company now stood on a firmer basis. Those changes could only be accomplished slowly, and four months were not long to do much in such matters, but as long as their progress was sure and on a right line, the shareholders ought not to complain. The business was taken over from the old company from the 1st July last. Since then they had not done badly in the matter of orders notwithstanding the general depression in trade. Their orders, he believed, were fully up to the average of previous years, and they ought to have a satisfactory profit upon them, but until their books were closed, he could not, of course, speak with certainty as to the result of work which was still in course of execution. In discussing this question of profit, it must not be forgotten that they had very extensive works equipped for carrying out more extensive orders than they had yet obtained, and they all knew that when factories were only partially employed, the work was not so economically done as when the plant and staff were working at their full capacity, for the standing charges and administration were the same whether much or little work was done. With regard to various subsidiary companies, in which so much capital was locked up, their policy had been to assist them into a sound position, and to do that without prejudicing the parent company, and without adding to their responsibilities, as their policy was to liquidate outstanding liabilities and to reduce their responsibilities. The Company looked forward with much hope to the development of electric traction, and their investments in this direction would help them to do further business. The work which they had done in the field of traction in South Staffordshire, Liverpool, and in other places, was the best recommendation they could have. Numerous engineers and representatives of local authorities had inspected their work, with the result that they had secured some contracts and were negotiating for several others. They had acted as pioneers in electric traction in this country and they were in a position to undertake and carry out successfully large contracts of this kind. A company had been formed in America to manufacture electrical apparatus of their design. They had not put any cash into the company but the latter had agreed to make their machinery, and in consideration for this they would assign to the Electric Construction Company an interest in the American Company. With regard to electro-chemistry, their views of which he expressed at the last meeting, they were now negotiating for working some of the patents in which they were interested, and in which they fully fully believed. In other branches they were getting their fair share of orders. He believed the Company's technical work was sound and without reproach. The working of the overhead railway at Liverpool was a revelation to electrical engineers, and the economy with which they were running the cars in South Staffordshire would suggest a new future for many tramways which were now working with horses and steam but without dividends. The Company would do all they could to develop the business, and they would not accept contracts unless they saw that they would yield a fair profit. He concluded by expressing his belief that with careful management and strict economy they might reasonably expect to have a prosperous future before them.

This terminated the business of the meeting.

An extraordinary general meeting was then held, when the following resolutions, in order to comply with the requirements of the Stock Exchange, were passed:

"1. That Article 60 of the articles of association of the Company be amended by substituting the words 'one tenth' for the words 'one fifth' in the fourth line thereof." The article will then read: "The Directors shall call an extraordinary meeting whenever a requisition in writing, signed by not less than one twentieth in number of the members of the Company, holders in the aggregate of not less than one tenth in amount of the capital then issued and paid up, and stating fully the general nature of the business for which the meeting is proposed to be called, shall be delivered to the Secretary, or left at or sent by post to the office."

"2. That Article 135 of the articles of association of the Company be amended by adding at the end of the article the words 'and a copy of such balance sheet and report shall be sent out, seven days previous to the general meeting, to those shareholders entitled to receive the same.'" The article will then read: "Once at the least in every year the Directors shall lay before the Company in general meeting a proper balance sheet and profit and loss account for the past year, made up to a date not more than four months before such meeting, and a copy of such balance sheet and report shall be sent out, seven days previous to the general meeting, to those shareholders entitled to receive the same."

WEST INDIA AND PANAMA TELEGRAPH COMPANY.

The thirty third ordinary general meeting of this Company was held on Wednesday at Winchester House.

The **Chairman** (Mr. C. W. Earle), in moving the adoption of the report, referred to the death of his colleague, Mr Henry Weaver, who was elected to a seat on the Board by a committee of shareholders nearly 20 years ago, and stated that the vacancy had been filled by the appointment of Mr. G. W. Balfour, M.P. He thought they might congratulate themselves on having had, for a West Indian company, rather a satisfactory half year. The normal traffic increased somewhat from the great reduction that occurred owing to the reduced rates forced upon the Company in 1891. In consequence of the breakdown of the cable of their competitor, the French Cable Company—the whole traffic of that line came upon this company's line at Martinique, and during the seven weeks they were interrupted they had an increase in traffic of about £2,800. The expenses of repairs to cable amounted to £10,720, being £12,358 less than those for the corresponding period. This decrease was due to fewer repairs and to the smaller quantity of cable used. The Directors, desiring to recognise the long and faithful services of some of the employés and to strengthen the good relations which existed between the Company and its staff, proposed to offer to bear one half the expenses of life or endowment insurances for some of those who had been in the Company's service a certain number of years. He could not say what the expense would be, but the saving effected by not filling up two vacancies on the Board would leave a good margin. The Board proposed to pay dividends of 6s. per share on the first and second preference shares respectively, and 1s. per share on the ordinary.

Mr. W. Andrews seconded the resolution, which was adopted.

LEGAL INTELLIGENCE.

THOMPSON v. COWLES SYNDICATE, LIMITED.

In the Queen's Bench Division on Tuesday, Baron Pollock gave judgment in this case, to which reference was made in our last issue. The case, his Lordship said, was somewhat intricate, and was commercially important. The action was to recover the price of 10,104 carbon smelting rods, the greater part of which had been rejected by the defendants on the ground that they had not been supplied according to warranty, and as to a small portion of the rods which they admitted to be of good quality, they paid a sum of money into Court. Now, he held that on the point of warranty the defendants must fail. It was quite clear to his Lordship that there was no warranty. The process of the manufacture of aluminium by electric smelting was a somewhat new one, and was not generally known—in fact, it appeared to be known to a few persons only, though the manufacture was carried on to some considerable extent by one firm in Switzerland. The process, therefore, could not be said to be known to the plaintiff except in the most general form, but upon reading the correspondence for more than a year between the plaintiff and the Paris manufacturer, M. Berne, and the defendants, and also from the evidence, he came to the conclusion that carbon rods, both for electric lighting and smelting purposes, were generally known in commerce, and that being so, the intention of the parties to the contract was immaterial. There was no warranty, and the only question was whether the defendants were entitled to reject the larger part of the carbons supplied on the ground that they were not of the commercial quality which they ought to have been as such goods were known in the trade—not because they were unsuited to any particular and general unknown process—but because they were not good marketable commercial carbons applicable to commonly known purposes. Having minutely examined the correspondence and the evidence his Lordship

came to the conclusion that the carbons supplied were of two different qualities, and that those rejected by the defendants were not of good marketable commercial quality. The evidence, which had been given very fairly on both sides, showed that the condition of the furnaces or crucibles containing the molten metal was the same when the defective carbons were used as when the good carbons were used, leaving the only inference that the beating and wasting of the carbon rods was due either to a defect in the manufacture or in the materials of the carbons. His verdict and judgment would therefore be for the defendants on the claim, with costs. With regard to the counter claim by the defendants for special damages for breach of warranty, it must fail, as he had held that there was no warranty. Judgment would therefore be for the plaintiff on the counter-claim.

Mr. Tindal Atkinson, in view of the important principle involved in the case, asked on behalf of the plaintiff for leave to appeal, which his Lordship granted on condition that £100 shall be paid into court within a week.

ELIESON ACCUMULATOR (BRITISH PATENT) SYNDICATE, LIMITED, v. THE EARL OF GALLOWAY.

In the Queen's Bench Division, before Mr. Justice Kennedy, sitting without a jury, an action was brought by the Elieson Accumulator (British Patent) Syndicate, Limited, against the Earl of Galloway to recover the sum of £400, alleged to be the amount due on the allotment of shares held by the defendant in the plaintiff company. The defendant put in numerous defences, the effect being that the application for shares was made without his consent or authority. The case for the plaintiffs was that on August 10, 1892, the defendant applied in writing, addressed to the secretary of the Electric Storage and Traction Syndicate, for 100 shares of £10 each, and enclosing a cheque for £50, being a deposit of 10s. per share. He handed the letter and application to a Mr. Watson Smith for the purpose of enabling Smith to procure an allotment. At the same time he told Smith that he would pay the balance of £950 within three months from the date of application. He further agreed with Smith that he would take 1,000 shares of £1 each in the plaintiff company, and he authorised Smith to procure such an allotment. On August 24, in pursuance of such agreement, the defendant wrote to Smith, enclosing a cheque for £50 as a deposit of 1s. per share. He subsequently asked Smith to transfer and treat his application for 100 shares in the Electric Storage and Traction Syndicate as an application for an additional 1,000 shares in the Elieson Syndicate.

After hearing evidence his Lordship reserved judgment, which is to be delivered on Monday next.

BUSINESS NOTES.

Coventry.—A supply of the electric light will be in operation by June next.

Conisborough.—It is stated that the works of Messrs. Kilner Bros. are to be lighted by electricity.

Western and Brazilian Telegraph Company.—The receipts for the week ended November 10 were £3,316.

Londonderry.—Messrs. Alex. Brown and Son, of Derry, have received the contract for supplying lamp pillars at £9 each to the Corporation.

Portobello.—The Town Council have remitted to a committee to enquire into the question of public lighting and all available sources of supply.

Ilfracombe.—The Ilfracombe Local Board has decided that seven electric bells shall be provided for summoning the fire brigade in case of fire.

Bury.—Aldermen Brierley and Parks, Councillors Butcher, Collinge, Byrom, Hopkinson and Thornley have been elected as the Electric Lighting Committee.

Ipswich Electricity Supply.—The petition for the winding-up of the Ipswich Electricity Supply Company, Limited, referred to in previous issues, has been struck out of the list.

Chichester.—A report on the cost of lighting the town by electricity has been submitted to the sub-committee of the Lighting Committee of the Town Council by Councillor Prior.

Canterbury.—The Town Council have made an order to affix the corporate seal to the deed of transfer of the Canterbury Electric Lighting Order, 1891, to the Canterbury Electricity Supply Company, Limited.

Normanton.—A discussion has taken place at a meeting of the Local Board as to what can be done in the way of lighting the public streets cheaper and better, but not a word was mentioned of the electric light scheme about which enquiries were made two months ago.

City and South London Railway Company.—The receipts for the week ending November 12 were £909, against £945 for the same period last year, or a decrease of £36. The total receipts for the second half year of 1893 show an increase of £201 over those for the corresponding period of 1892.

The Way to Do Business.—We cull the following from the *Blackpool Gazette*: "Several large deputations have visited Blackpool lately to inspect the new electricity works, and arrangements are being made for others in the early future. On these occasions hospitality is very freely dispensed by Mr. Robert Hammond.".

Swansea.—A scheme is on foot for the establishment in the neighbourhood of Landore of new large works for the electrical deposition of copper and other metals. The matter has not yet assumed a definite form, but it is being discussed by some of the wealthiest and most important people engaged in the metal trades.

Amalgamation.—The firms of Messrs. Theiler and Sons, of Canonbury, and Messrs. Elliott Bros., of St. Martin's lane, are amalgamating under the title of Messrs. Elliott Bros. Mr. G. K. B. Elphinstone, the representative of Messrs. Theiler and Sons, and Mr. W. Smith, the chief of Messrs. Elliott Bros., will be co-partners.

William Banks and Co., Limited.—This Company has been registered with a capital of £4,000 in £5 shares to acquire and carry on the business of opticians, mechanical and electrical engineers, and manufacturers of photographic apparatus hitherto carried on at 32, Corporation-street, Bolton, under the style of William Banks and Co.

Rotherham.—Major Hirst, in seconding the motion for the election of the mayor the other day, observed that it was time the town had better light. The best thing they could do was to go into the subject of electric light. If it was established in the borough it would not only reflect light, but credit on those who had undertaken the work.

Wigan.—The following gentlemen have been appointed as the Gas and Electric Lighting Committee of the Town Council: Messrs. Ackerley, Benson, Booth, Millington, Henderson, Hilton, Riley, John Johnson, Richards, J. Woods, Riddlesworth, Rigby, Smith, Ashton, Richard Johnson, C. B. Holmes (chairman), and John Gee (vice chairman).

Newcastle.—The Corlett Electrical Engineering Company, Limited, having head offices at Wigan, has opened a branch establishment at Newcastle-on-Tyne. This will be under the management of Mr. C. W. Fairweather, who for the past few years has been works manager for Messrs. Ernest Scott and Mountain, Limited, Newcastle-on-Tyne.

Southend.—The Town Council, according to the Pier Committee's report, intend to keep the electric light and tramcar plant in good order, and the committee will arrange with Messrs. Crompton and Co., Limited, to make five inspections over next 12 months—one at once, another immediately before the commencement of next season's running, and three others during the season—for the sum of £25.

Grimsby.—The Town Council, to whose proceedings in connection with electric lighting we referred in our last two issues, held a meeting on the 10th inst. to authorise the application for a provisional order. The Mayor explained that that was a statutory meeting, according to the Act of Parliament, one month's notice having been given, and he therefore moved the authorisation of the application. Mr. Jeffs seconded the motion, which was carried unanimously.

Lee Lamp (Parent) Company, Limited.—This Company has been registered with a capital of £50,000 in £1 shares to carry into effect an agreement made between J. Hodgson Lee and this Company, and to carry on the businesses of manufacturers of and dealers in lamps for lighting, heating, etc., by the agency of oil, gas, electricity, or other means. The first signatories are C. F. H. H. Bagot, W. J. B. Chetwynd, C. M. E. Wynne, T. Kaye, R. P. Lee, T. J. Crawley, J. Goodman.

Portsmouth.—A certificate, presented by Messrs. Waller and Manville, for payment to the contractors for conduits, etc., in connection with the electric light, to the amount of £1,900, was ordered to be paid by the Town Council last week. The following were appointed as the Electric Lighting Committee: The Mayor, Aldermen Ellis, Scott Foster, Cudlipp; Councillors Beale, Ashdowne, Avens, Dean, H. Kimber, F. G. Foster, Croucher, Dittman, Corke, Ross, Bamber, Fulljames, Dummer.

Falmouth.—The Town Council, after receiving the report of Messrs. Veale and Co. on the electric lighting of the town, passed the following resolution: "That the chairman and members of the Lighting Committee be thanked for the services they have rendered in obtaining so much valuable information in the matter of lighting Falmouth with electric light, and that they be invited to communicate with the gas company, or any person, with a view to obtaining further information on the subject."

Wakefield.—Councillor Walter Wade, the new mayor, promised on his election to give his attention to the extension of the waterworks, the sewage works, and the proposal to introduce the electric light, and he expressed a hope that certain street improvements would be carried out. The Mayor, Alderman Carter, Councillors Booth, Hall, Harrison, Haslegrave, W. Moorhouse, Nicholson, Rhodes, Saville, Smith, and Stonehouse have been appointed members of the Electric Lighting Committee.

Tunbridge Wells.—As mentioned in our last issue, the Corporation have decided to spend £13,000 on electric lighting, and now a Local Government Board enquiry on the subject has been held. The Town Clerk stated that they did not at first propose to go in for the entire substitution of electricity for gas, but only for a part of the borough as an experiment. A site for the electric light station has been secured near the Grosvenor Bridge, close to the South-Eastern Railway. It is proposed to adopt the high-pressure system.

Tiverton.—An arc lamp of 1,500 c.p., outside Ford's Brewery, Tiverton, was lighted for the first time last week. When a large portion of the brewery was destroyed by fire some time ago, Messrs. Ford and Son determined to substitute electric light for gas. During the last two months Messrs. Stenner and Co., engineers, Tiverton, have been supplying and fitting the necessary

plant. An 11-h p. turbine fixed in a leat running into the Lowman drives the generating dynamo. There are 100 16 c.p. lamps on the premises.

Crieff.—Some time ago a proposal was brought before the Crieff Town Council for the introduction of the electric light into the town. Since then, Sir Patrick Keith Murray, Bart., of Ochtertyre has offered the use of the Falls of Barvick, two miles from the town, to be utilised for the motive power for generating the current, and at a meeting of the Council on Monday, Provost Adie urged upon the Board to take advantage of Sir Patrick's offer, and stated that he would shortly lay before the Board a scheme for this purpose.

Derby.—The Electric Lighting Committee, at a meeting of the Town Council last week, applied for a further £5,000 to extend the mains from the top of Traffic-street to the Midland Station, through Friar-gate to Vernon-street, and for laying down a 200 h.p. engine. Mr. Marsden moved a resolution to this effect. Alderman Newbold strongly opposed the grant of more money upon an experiment. Sir A. Haslam also opposed the proposal. Several other members having spoken in favour of the motion, it was carried by a majority.

New Installations at Richmond.—We hear that Mr. C. A. Hemingway, of 10, Petersham-road, Richmond, is carrying out an installation at the establishment of Mr. John Cockburn, jeweller, etc., George-street, Richmond, Surrey, where 60 lamps of 16 c.p. are being fitted. Mr. Hemingway has also carried out installations at Mr. T. J. Palmer's, chemist; Mr. G. H. Young's, wine merchant; Mr. Arthur Greeves's, hatter, etc.—all of George-street. Mr. Young's was the first shop in Richmond to be lighted by the electric light.

Dover.—The surveyor reported, at a meeting of the Town Council last week, that the telephone company were willing to connect the drainage works with his residence for £9, but he thought, considering the many facilities that they had obtained from the Corporation, better terms should be made. Alderman Peake moved that the total amount paid to the telephone company by the Corporation be ascertained. He thought they should get something in exchange for what they gave the telephone company. A report was ordered to be prepared.

Phosphor Bronze.—The Phosphor Bronze Company, Limited, of 87, Sumner-street, Southwark, S.E., inform us that they have appointed Messrs. Dempster Moore and Co., of 49, Robertson-street, Glasgow, as their sole agents in Glasgow for the sale of their manufactures—namely, phosphor bronze alloys, Duro metal (for bearings), plastic metal and white brass Babbitt's and other white anti-friction metals, Bull's metals for propellers, forgings, and stampings, manganese bronze, phosphor tin and phosphor copper. A small stock of some of these metals will be kept at the agents' warehouse, 49, Robertson-street, Glasgow.

Transmission of Power.—The Moodie Gold Mining and Exploration Company, of South Africa, have now concluded contracts with Messrs. W. T. Goolden and Co., of Woodfield Works, Harrow-road, London, W., for the supply and erection of plant for the electrical transmission of 250 h.p. generated by water power of the Queens River, to the various mines situated near Barberton, a distance of about 10 miles. This is the most important power-transmission scheme yet undertaken in South Africa, and if successfully carried out must have an important bearing on the future of some of the South African gold mines.

Tenders for Dublin.—The Corporation invite, on or before 14th December, tenders for the extension of the buildings, and the supply and erection of additional plant at the central station, Fleet-street, Dublin. Plans may be seen and specifications and forms of tender obtained at the office of Mr. Spencer Harty, C.E., city surveyor, City Hall, Dublin, on payment of one guinea, which will be returned to all persons sending in a *bona fide* tender. Tenders to be enclosed in a sealed envelope, addressed and forwarded to the Town Clerk, City Hall, Dublin, and endorsed "Tender for the Extension of Buildings at the Electric Lighting Station," or "Tender for the Supply of Electric Lighting Plant," as the case may be.

Ramsbottom.—The chairman of the Local Board moved at a meeting of that authority that they should write to the Board of Trade for provisional powers for lighting Ramsbottom by electricity. Mr. Barlow seconded the motion. The Chairman said he had been in communication with a firm of electrical engineers, and they had satisfied him that the work could be done cheaply. He could not give them any particulars, but at any time if any member wanted to know, he (the chairman) would give them particulars as to quantity, cost, etc. He would inform them where it was proposed to fix the plant, how many "arc" lights there would be needed for lighting the main streets, and what preparation would be required for incandescent lamps for supplying shops and mills. The resolution was adopted.

York.—On the consideration of the Streets and Buildings Committee's report, at a meeting of the Council on Wednesday, a long discussion took place on the action of the members of that committee who had visited Scarborough and Huddersfield for the purpose of inspecting the Parsons system and the Brush system of electric lighting. Four firms had contracted for the electric lighting of the city, and it was urged that the committee ought not to have visited these towns at the invitation of two of the contractors, and allowed them to pay the railway fare and entertain members of the committee to dinner during their visit. A resolution was passed stating, that whilst the Council fully acquitted the Streets Committee of any irregularity, the Council was of opinion that the expenses of its committees on city business should be defrayed out of the rates of the city.

Camberwell.—The Vestry have adhered to their previous resolutions requiring the wires for fire alarms at Dulwich to be placed underground. At a meeting of the Vestry last week, Mr. E. R. Phillips, chairman of the Electricity Committee, presented a report with reference to the proposed application for a provisional order to establish electric lighting in the parish. The committee recommended "That the Vestry approve the following streets—viz., Camberwell-road, Camberwell-green, Church-street, Peckham-road, High-street, Peckham, Queen's-road, Peckham (from High-street to railway station) Rye-lane, and Old Kent-road—as being streets through which distributing mains for general supply are to be laid within two years from the commencement of the order." The recommendation was adopted.

Taunton.—The Electric Lighting Committee of the Town Council reported last week that they had engaged for 12 months (through the Electrical Standardising Institution) the services of Mr. A. J. Howard as an improver, upon payment by him of the sum of £50. The committee were unable to report upon the proposed extension of the electric lighting works owing to Dr. Fleming not having sent his report, but they hoped to be able to report fully thereon at the next Council meeting. Alderman Standfast expressed surprise that the report of Dr. Fleming was not forthcoming, especially as he understood that the cable was carried to Mr. Steevens's place on the strength of what that report said. The following were appointed as the Electric Lighting Committee: Alderman Chapman, Councillors Hartnell, Sibley, Goldsmith, Steevens, Potter, A. Goodman, and Hammett.

Cheltenham.—On Wednesday an enquiry was held by Colonel Hasted, R.E., Local Government Board inspector, at Cheltenham, into the application by the Corporation for leave to borrow £16,000 for the purpose of electric lighting in the borough. Mr. Brydges (town clerk) called Mr. Norman, who described the various steps taken in the matter by the Electric Lighting Committee, of which he had been chairman up till November 1. The borough surveyor (Mr. J. Hall, C.E.) afterwards gave estimates, and explained the scheme of lighting, which is to be the alternate-current system, as recommended by Profs. Ayrton and Preece. Two or three ratepayers were heard in opposition, and the enquiry closed. The Mayor, Aldermen Griffith and Thoyts, Councillors King, Lawrence, Parsonage, Ward-Humphreys, and Woodard have been elected members of the Electric Light Committee of the Town Council.

Douglas and Laxey Coast Electric Tramway.—As mentioned in our last issue, tenders are invited for the extension to Laxey of the existing line from Douglas to Groudle Glen. The works to be tendered for are in two sections, numbered 2 and 3. Section No. 2 comprises a roadway 2,200 yards in length, and about 40ft. wide, and laying a 3ft. gauge railway line on one side; it also includes a masonry bridge, 50ft. high, with three 20ft. spans, and a culvert, 100ft. long, 7ft. span, and 13ft. high. Section No. 3 comprises the formation and laying of a railway line, 3ft. gauge, and about 6,000 yards long—rails, sleepers, fastenings, electric plant, and rolling-stock are not included. Plans can be seen at the office of Mr. F. Saunderson, C.E., Athol-street, Douglas, Isle of Man, and specifications, quantities, and forms of tender obtained upon payment of two guineas, which will be returned on receipt of a bona fide tender. Tenders to be delivered at the office of Douglas and Laxey Coast Electric Tramway, Limited, 7, Athol-street, Douglas, Isle of Man, by 25th inst.

Wolverhampton.—It is proposed to erect some extensive engineering and electrical works at Wolverhampton. The Town Council have already sanctioned an application for the rails from the Midland goods station to be laid across the Wednesfield-road to land on the opposite side of the road, which will be the site of the proposed works, and a railway siding will be provided. The site consists of between three and four acres of vacant land, which is level, and will form a suitable position. The works will be adjacent not only to the Midland goods depôt, but in close proximity to the main line of the Great Western Railway Company. The only works of the kind in the neighbourhood are those of the Electric Construction Company at Bushbury. The new Mayor, speaking after his election last week, said, with regard to the electric lighting scheme, that the land had been bought for the station; that the committee had enquired thoroughly into the matter; and that he thought he might safely say that before next winter they would have a plant second to none for its size in the kingdom.

Halifax.—On the proposal of the names suggested for the Gasworks and Electric Lighting Committee—the names being Aldermen Brear, E. Robinson, Patchett, Councillors Beever, Hodgson, Braithwaite, Woodhead, T. Greenwood, Rushworth, Dr. Smith, W. H. Spencer, I. Firth, and Hartley—Alderman Patchett proceeded to explain that he desired to make the number on this committee 16, and that out of it should be formed the Electric Lighting Committee. The additional names he proposed were Alderman Brook, Councillors G. H. Smith, Butler, Wade, and Bunney, and leaving off the committee suggested Dr. Smith and W. H. Spencer. The ex-Mayor seconded this. Councillor Woodhead objected to the proposal on the ground that the motion would interfere with the equal representation of the wards, four having double the allowance of the rest. He thought the Electric Lighting Committee, considering that they were proposing to spend £30,000, should be a separate committee, consisting of not less than 12 members, each ward to have equal representation. For the amendment there voted 24 members, and 16 against.

Poole.—A meeting of inhabitants of Poole, Parkstone, and Bournemouth has been held at the Poole offices of Mr. F. G. Wheatley, mayor of the borough, to discuss a proposal with regard to the

construction of an electric tramway between Poole and the County Gates, Bournemouth; and also for the supply of the electric light to Poole, Parkstone, and a large part of the district lying between those places and Bournemouth. Powers have already been obtained from the Board of Trade for the carrying out of these undertakings; but the question has arisen whether it would not be more economical to amalgamate the two schemes under one management. The schemes were received with considerable favour. Mr. Gordon Smith made a statement with regard to the character and cost and probable success of the undertakings, and a resolution was carried pledging that the inhabitants of Poole, Parkstone, Bournemouth, and district should do everything to facilitate the carrying through of the scheme for laying down electric tramways between Poole and Bournemouth, and the electric lighting of the town and district of Poole. Mr C Bastin, Amesbury Villa, Serpentine-road, Poole, has the schemes in hand.

Colliery Lighting.—Messrs. Ernest Scott and Mountain, Limited, of Newcastle, have received an order from the Coltness Iron Company, Newmains, Lanarkshire, for an electric light installation for their colliery, and which will be one of the most complete plants in existence. The plant consists of a complete electric light installation for the colliery, consisting of dynamo to run 200 16 c.p. lamps, and about 180 lamps throughout the pit, both above ground and underground. The second is an installation for the lighting of 34 workmen's cottages, which are about 200 yards from the colliery, there being three lights placed in each cottage, or a total of 102 lamps in all. The third installation consists of a complete electric pumping plant capable of delivering 100 gallons of water per minute from the river to the colliery. The dynamos for the lighting of the pit and workmen's cottages are being specially constructed, so that either dynamo can be utilised for either purpose, both machines being over-compounded, so that the E.M.F. will remain constant at the cottages under variations of load. This installation is probably one of the first in which complete plant for pumping, lighting of a colliery, and the lighting of workmen's cottages has been adopted.

Result of Tenders.—The following tenders have been received for the construction of chimney shaft at the East St. Pancras central station, King's-road, N.W., for the Vestry of St. Pancras:

Burman and Son, Delauno Works, Kennington	£5,718
Jerrard, 40, Loampit-vale, Lewisham	4,800
Spencer and Co., 32, Commercial road, Lambeth	4,676
H. Wall and Co., Carlton-road, N.W.	4,650
Godson and Son, Pembroke Works, Kilburn	4,567
C. Wall, Lots road, Chelsea	4,450
Mowlem and Co., Grosvenor Wharf, S.W.	4,421
Holden and Myles, Stalybridge	4,168
Smart, Trent Bridge, Nottingham	4,094
J. E. Johnson and Son, Leicester	3,860
J. Stead, Chalk Farm road	3,854
Kellett and Co., Willesden	3,557
Kelly Bros., Liverpool	3,437
W. Neil, 165, Turners road, Burdett-road	3,332
J. Yates and Co., Hollybrook-road, Ratcliff	3,100

The tender of Messrs. Yates and Co. having been withdrawn, that of Mr. Neil, for £3,332, has been accepted.

Tullie House at Carlisle.—The Institute of Literature, Science, and Art established by the Corporation of Carlisle at Tullie House has been formally opened. The scheme for the introduction of the electric light was prepared by Mr. Howard Smith, the city surveyor and architect of the new building, and was carried out under his supervision. The dynamo and engine room is located in the basement of the building. The engines are duplicates, and have been supplied by Messrs. Tangyes, of Birmingham. They are each of 16 nominal horse power, but are capable of developing 35 h.p. The engines run at a speed of 160 revolutions per minute, and drive the dynamos at a rate of 600 revolutions per minute, giving an E.M.F. of from 100 to 105 volts, and producing 200 amperes. The dynamos are two in number. The current from the dynamos is conducted to a main switchboard, where it is divided into seven circuits. The lamps which have been supplied are the Edison Swan incandescent type, and number altogether throughout the building close upon 420, varying from 8 c.p. to 32 c.p. and 50 c.p., and giving an equivalent of 566 of 16 c.p. lamps. The dynamos and electrical apparatus and lamps have been erected by Messrs. Latimer Clark, Muirhead, and Co., of Westminster, the contractors for the whole of the electrical work, which has been carried out by Mr. W. E. Weiss, their representative. The engines and dynamos, as well as the heating apparatus, are under the charge of Mr. Tom Duckworth.

Blackpool.—The Markets and Gas Committee recommended, at a meeting of the Town Council last week, that the gas manager should be authorised to utilise as much of the old electric lighting plant in the town's yard, Victoria street, for gas purposes as may be available, and to sell any plant not required; also to remove all electric light posts not now required for electric lighting purposes on the Promenade. Mr. Alderman Cocker moved that both these recommendations be referred back. He asked where was the gas manager to use the plant; and whether the gas manager should interfere with the electric light? It had never been decided that the old lights should be done away with, and they could talk as they liked about the superiority of the new lamps, but it was worth Blackpool's while to pay for the old lamps to be retained, even though for advertising purposes only. Mr. Councillor Dickinson said that he would second the amendment as applying to the posts, for they were of value as ventilating shafts for the sewers. It was stated, in reply to Mr. Councillor Hampson, that three of these posts were connected with the sewer. Mr. Councillor Heap pointed out that these old lamps cost the town between £800 and £900 per annum to maintain. Mr. Alderman Cocker said it was even worth £900 or £1,000 per year to have these large lights between the two northern piers. Mr. Councillor Pearson said Mr. Councillor Hampson surely knew that a complete scheme had been got out for the lighting of the streets running off the Promenade. The old lamps had been condemned by electricians, and it had been proved that the lamps consumed three times as much current in proportion to the light they gave. It was an exceedingly expensive and obsolete system, and there was no necessity for the ugly posts to remain up any longer. The amendment was not carried. Mr. Councillor Hampson then proposed a further amendment that the iron posts remain standing. Mr. Alderman Bickerstaffe seconded, and, after further discussion, a vote was again taken, 10 voting for the amendment and nine against. The iron posts will therefore remain in their present position.

Lighting at Manchester.—As mentioned in previous issues, the Manchester Corporation, on the advice of Dr. J. Hopkinson, have had erected a central station on the five-wire system. The station is situated in Dickenson street, and for the portion of the scheme now in operation six engines of 90 h.p. and four of 250 h.p. have been built. Six large Lancashire boilers provide the steam power. A dynamo is connected to each engine. The conduits are composed of concrete and flagged at the top. In places where the traffic is heavy—at street crossings, for instance—iron pipes take the place of the conduit, and here the cables bearing the current are solidly protected. In the conduits themselves the only protection necessary is air insulation. In considering the question of cost, remarks a Manchester paper, we are soon in the region of comparison. Our commercial instincts naturally lead us to enquire whether the new illuminant is as cheap as the old, and those in search of information on this point will learn that the Corporation has two sets of charges. On one scale the charge is 8d. a unit; on the other a fixed charge is made for the plant, and in addition 2d. a unit. The consumer may make his choice, and in doing so will be determined by the nature of the supply that he requires. Once provided with a supply, he will probably find that if he should use it to a very limited extent electricity will be dearer than gas. On the other hand, he will find that if he should make use of electricity during 960 hours in the course of a year on the fixed charge, and 2d. a unit scale, the expense, observes the same paper, will be about the same as if he burned gas at a cost of 2s. 6d. per 1,000ft. during a similar period. Burnt for 960 hours during a year on the scale mentioned, electricity will cost 5d. a unit, and at this rate it is about the same price as gas. The people of Manchester have shown their appreciation of the benefits of the new supply in an unmistakable manner. Already the resources of the Dickinson street works, and the plant at present in use, are being tested to the full extent. So far the area of supply is confined to the centre of the city, but the requirements of the people outside these limits will be met as they are made known. The consulting engineer, Dr. Hopkinson, had as his local representative Mr. Charles Hopkinson, M.I.C.E., Princess street, Manchester, who attended to the practical work of superintending the construction of the work and the laying down of the plant. Mr. Wooler is the electrical engineer in charge.

Lighting of the City.—At the meeting of the Commission of Sewers last week, as referred to in our previous issue, a statement was made by one of the speakers concerning the cost of lighting the streets with electricity and with gas. The difference was very wide, and in order to obtain some further information upon it a representative of the *City Press* has since called at the offices of the City of London Electric Lighting Company, Great Winchester-street, where he had a conversation with one of the officials. The following is the substance of it: "You ask the difference in cost," said the official referred to, in response to an opening remark. "The simple answer is that you get so much more light than under the old system. It is value for money expended. There have been replaced by electricity 1,219 gas lamps of 16 c.p. each, totalling up to 20,000 candles. The arc lamps now in position are 478 in number, out of 515 provided for in the contract with the Commission of Sewers. These lamps give a light of 1,000 candles each, making in the aggregate 478,000 candles, or, say, 23 times as much light as with gas. The company are still waiting for the order from the Commission to proceed with the lighting of the side streets, and also for positions to be assigned to 33 arc lamps, which, with four now in course of erection, will complete the total of 515 already named." "But this increase of cost over the old system of lighting—has it come as a surprise—is it a new revelation? I mean, of course, to those who should be in a position to know officially?" "Not at all. It was well known what the cost would be according to the contract, which was entered into in May, 1890. The charge was fixed at £26 per year for arc lamps, £10 per year for incandescent lamps of 200 watts, and £5 for lamps of 100 watts." "Then you think there is no reason for complaint as to cost, and none for surprise at the increase?" "As already stated, there has been no change made in the contract, and the figures given show what an enormous difference there is in the amount of light supplied." "Leaving the streets now, are orders for private lighting coming in well?" "Yes; already the company are supplying about 40,000 incandescent lamps, and in a week or two this number will be very largely increased." "Complaints are heard every now and then that private consumers cannot get 'joined on' to your system." "Quite so. People see the lamps outside their doors, and wonder why the light cannot be brought into their houses at once. But the street lamps are run on a different system from the private, and the light cannot be put on the public lighting circuit. Depend upon it, the company are most anxious to push on the private light-

ing as much as possible. It is to their interest to do. It means increased revenue. There is one matter that I should like you to make a note of, if you will. It is that of 'failures' of lamps The report upon these gave a total of 302 lamps as having failed in six months, which, of course, appears a very large number But many of these failures were but for a moment or so, perhaps Put into lamp hours the thing wears quite a different aspect Thus there were 787,245 hours, and the failures amounted to only 370 hours."

Cambridge.—The Electric Lighting Committee of the Town Council reported at a meeting of the latter last week that they had received the following letter from the manager of the Cambridge Electric Supply Company, Limited: "By the regulations made by the Board of Trade, under the provisions of the Electric Lighting Acts, and of the Cambridge Electric Lighting Order, 1890, it is provided that the supply of energy by the company shall, except so far as may be otherwise agreed on from time to time between the local authority and the company, be constantly maintained. My directors find from the experience gained up to the present time, that the maintenance of a constant supply throughout the year results in considerable pecuniary loss to the company, without any corresponding benefit to the public. They, therefore, desire to come to an agreement with the Corporation that for the present there shall be the following exceptions to the delivery of a constant supply viz., on weekdays during the period between October 1 and June 25 from 2 a.m. to 6 a.m., and during the period from June 26 to September 30th from 1 a.m. to 5 p.m. On Sundays during the period between 1st October and 25th June from 9 a.m. to 5 p.m., and from 1 a.m. to 6 a.m., and during the period from June 26th to September 30th from 1 a.m. to 6 p.m. As soon as the consumption of current warrants the delivery of a constant supply without exceptions, it will be the pleasure as well as to the interest of my directors that this shall be effectively maintained I shall be obliged by your bringing the matter before the Electric Lighting Committee as early as possible The chairman, a director, and myself would be glad to attend as deputation to the committee and lay the matter more fully before them." The committee recommended that from the present time until the 31st day of December, 1894, the company be permitted to make the following exceptions to a constant supply—viz., on weekdays from the 1st of October to the 25th of June inclusive, from 2 a.m. to 6 a.m. From the 26th of June to the 30th of September inclusive, from 2 a.m. to 5 p.m. On Sundays from the 1st of April to 30th of September inclusive, from 1 a.m. to 6 p.m. From the 1st of October to the 31st of March inclusive, from 1 a.m. to 4 p.m. But in no case on Sundays shall the supply be shut off after sunset. Alderman Kett, who proposed the adoption of this report, remarked that the engineer said that as soon as they got further demands from the public the company would only be too glad to have a continuous supply. The company asked that for a time only an intermittent supply should be dealt out Councillor Ginn, who seconded, said that the committee thought the company, being a new company, and the Corporation interested in its success, that they should meet them as far as they possibly could. Councillor Nichols was strongly opposed to the adoption of the report. He moved as an amendment that the Council proceed to the next business. Councillor W. F. Taylor seconded the amendment, which, on being put, was lost. Councillor H. M. Taylor then said they had no guarantee that some persons to whom the electric light was supplied would not be very much wronged if they passed the report of the committee. He thought the company ought to assure them that they had made application to their customers, and they ought to tell them how many of those customers were willing to consent to the alteration they proposed to make. He proposed as an amendment "that the consideration of the report of the Electric Lighting Committee be postponed until the next meeting." Councillor F. Morley seconded this amendment, which, on being put to the meeting, was carried. The Town Council subsequently decided, on the recommendation of the Guildhall and Building Committee, to instal the electric light in the rooms in the Guildhall occupied by the School of Art. An estimate for the work, amounting to £17, had been obtained from Messrs. Russell and Co., and this was accepted.

PROVISIONAL PATENTS, 1893.

NOVEMBER 6.

21007. **Improvements in electrical arc lamps.** Charles Edward Harold Edman and Joseph Green, 18, Southampton buildings, Chancery lane, London.

21046. **Improvements in electric switches** Arthur Moore Thompson and William Walter Gerald Webb, Holly Bank, Crewe.

NOVEMBER 7.

21094. **A method of improving electric light switches, bell-pushes, keyhole-plates, door numbers, name-plates, dials of clocks, house fittings, and the like, by the application of luminous paints thereto.** Herbert Furnell Laughton, 20, Warrington crescent, Maida Vale, London.

21117. **Improvements in and relating to electrical dynamometric governors.** Robert Willsher Weekes, 70, Market street, Manchester.

21192. ***Improvements in incandescent electric lamps.*** *Gilbert Scott Ram 32, Oakley-square,* London.

NOVEMBER 8.

21199. **Power transmission by alternate-current motors.** Wilfrid L. Spence, 9 Newark drive, Pollokshields, N.B.

21201. **A multiple circuit microphonic transmitter.** Frederick Thomas Trouton, Caerleon, Killiney, co. Dublin.

21270. **Improvements in and in constructing pianoforte cases for lighting music-desks by electricity.** James Alfred Murdoch, 53, Chancery-lane London.

NOVEMBER 9.

21324. **Improved electric cables, and method of and apparatus for manufacturing the same.** Sebastian Ziani de Ferranti, 6, Lord-street, Liverpool. (Complete specification.)

21327. **Improvements in electric meters.** Emanuel Bergmann and Carl Erben, 6, Lord street, Liverpool.

NOVEMBER 10.

21370. **Improvements in mouthpieces for telephone transmitters.** William Henderson Turcan and Robert Connell Morton, 87, St. Vincent street, Glasgow.

21379. **Improvements in the application of electric light for photographic purposes and apparatus therefor.** Andrew George Adamson, 154, St. Vincent-street, Glasgow.

21420. **Improvements in primary batteries.** William Heaton Longsdorf, 73 Cheapside, London. (Gardner Hewett, United States.)

21430. **Improvements relating to incandescent electric lamps.** Charles John Peach Robertson, 6, Bream's buildings, Chancery lane, London. (Complete specification.)

21434. **Improvements in electrically-heated ovens.** Friedrich Wilhelm Schindler, 433, Strand, London.

21435. **Contact device or circuit connection for electric heating bodies and analogous electrical appliances.** Friedrich Wilhelm Schindler, 433 Strand, London.

NOVEMBER 11.

21496. **Improvements in the working of railway points and signals by electricity** Illius Augustus Timmis, 2, Great George street, Westminster.

21529. **Improvements in electrolytic cells.** Ludwig Mond and Robert Ludwig Mond, 6, Lord street, Liverpool.

21551. **A device for the prevention of local action in electric batteries and improvements in connection therewith.** Harry Theodore Barnett, 14, Narcissus-road, West Hampstead, London.

SPECIFICATIONS PUBLISHED.

1890.

16613. **Incandescent lamps.** Mehrle. (Second edition.)

1892.

18700. **Electrical ceiling roses.** Poole and others.

20488. **Closing an electric circuit by the passage of a train over a line of railway** Webb and Thompson.

20789. **Transmitting sounds electrically.** Lorrain. (Chamond.)

21372 **Electric insulators.** Espeut.

23658. **Electrical cables, etc.** Edmunds.

1893.

6935. **Electrical meters.** Brookes. (Wirt.)

10535. **Electrical signalling and printing telegraph systems.** Johnson (M'Caskey.)

10843. **Electric railways and tramways.** Claret and Vuilleumier

15906. **Electrolytic apparatus.** Young (Société Outhenin Chalandre Fils et Cie).

16562. **Electric motors.** Willcox. (Esmond.)

17127. **Electrolytic cells.** Cranoy.

17658. **Electric current conveyers.** Barker. (Lawrence Electric Company)

NOTES.

The Gale has played havoc with the telephone and telegraph wires.

Aluminium and Coal.—The price of aluminium is falling; so is that of coal.

Sunday Telephony.—The Cardiff telephone exchange is to be kept open on Sundays.

Nancy.—It is proposed to establish an aerial electric tramway between Nancy and Dombasle (Meurth and Moselle).

Central London Railway.—The London Central Railway Company will apply to Parliament next session for an extension of time.

Oban.—An industrial and fine arts exhibition has been opened. The halls are lighted by electricity by the Caledonian Electric Supply Company.

An Enterprising City.—There are 50 miles of electric railway and 1,600 telephones in use in Grand Rapids, Michigan—an enterprising city of 90,000 inhabitants.

Society of Arts.—A silver medal has been awarded to Mr. Gisbert Kapp for his paper read last session on "Some Economic Points in Connection with Electric Supply."

Measurements.—Lectures on industrial measurements are about to commence in Paris at the Laboratoire Central d'Electricité under the auspices of the Société Internationale des Electriciens.

Wakefield.—The Wakefield Corporation intend to apply to the Board of Trade for a provisional order authorising the supply and distribution of electricity for public and private purposes within the city.

Locomotion in London.—The London County Council have voted the sum of £500 for obtaining information on the subject of locomotion in London. The matter is referred to fully in another column.

Tasmania.—An international exhibition is to be held at Hobart in 1894-95. An influential London committee has been constituted, with offices at Tasmania Government Office, 5, Victoria-street, London, S.W.

Roubaix.—The Compagnie Nouvelle des Tramways Roubaix-Torcoing has obtained permission from the Municipal Council of Mouveaux (Nord) to construct an electric tramway on the overhead system.

Women's Voices.—It is stated that women's voices do not "carry" well on long-distance telephone lines. Their high notes do very well over short lines, but are not heard distinctly enough on the longer lines.

The Electro-Harmonic Society.—The "ladies' night" of this society will take place this evening in the Banquet-room of the St. James's Hall Restaurant, Regent-street, W., at eight o'clock. The programme was given in our last issue.

Society of Arts.—On Monday a lecture on the "Art of Book and Newspaper Illustration," by Mr. Henry Blackburn, will be given; and on Wednesday a paper will be read on the "Regulation of Street Advertising," by Mr. Richardson Evans.

Gas Again.—An accumulation of gas in one of the conduits of the Manchester municipal electric light undertaking led to an explosion last week, resulting in the upheaval of a manhole cover and the partial destruction of a portion of a main.

Treatment of Phthisis by Ozonised Air.—M. Hérard has analysed a note by MM. Labbé and Oudin regarding the treatment of phthisis by ozonised air obtained by electricity. M. Hérard concludes favourably on the application of this method.

Londonderry.—The report of Mr. Blake, electrical engineer to the Corporation, and which was recently presented, dealt with the progress made in the erection of generating stations, laying underground cables, lamp-pillar erections, and similar operations.

The Theatrophone.—Instruments of this kind have been introduced in Dover. Recently the Folkestone Theatre was connected up by a special wire, and some subscribers in Dover and other parts of Kent had the pleasure of listening to the performance of the musical burlesque "Little Godiva."

Science Master.—A science master having special knowledge of chemistry and physics is required for the Kingston-on-Thames Endowed Schools. The salary is £250 per annum, and particulars are obtainable from Mr. John Durham, clerk to the governors, Kingston-on-Thames Endowed Schools, Kingston-on-Thames.

The Blackpool Cars.—Delays in the working of the cars are reported to be constant. It is said that the plant which produces, or which should produce, the current is worked out. New engines and dynamos have, it is stated, been ordered to be in readiness for the time when the plant will be transferred to the electric light works.

Government and Telephony.—Mr. A. Morley, in reply to Captain Bagot, on the 17th inst., said that he could not state when the terms of the agreement between the Post Office and the National Telephone Company would be laid on the table of the House. There were still some points to be considered, but there should be no delay

Obituary.—M. Paul Jousselin, the president of th Société des Ingenieurs Civils de France, has just succumbed to an attack of pneumonia. Mr. James Brand, who died suddenly at Sanderstead Court, Surrey, on Tuesday, was largely interested in British telephone undertakings, and was formerly chairman of the National Telephone Company.

Serious Fire.—A large five-storey factory, used for the manufacture of electrical appliances and for supplying Halifax shops with electric light, was burned out yesterday morning. A gable fell out on to the residence of Mr. Emmott and demolished a great part of it. The damage will prove very heavy, and the electric lighting of about 50 shops has been cut off.

They Did not Like Welsh.—One day last week, according to rumour, a gentleman was using the telephone at an hotel in Wales and speaking in Welsh to a friend in another part of the town. Owing to a slight hitch, the conversation was not carried on as rapidly as could be wished. "Stay a moment," said the Hebe in attendance, "let me speak it in English. Perhaps the wires can't carry Welsh."

The International Maritime Congress.—The "Minutes of Proceedings" of the International Maritime Congress, held a few months ago in London, have now been issued by Messrs. Unwin Bros., of 27, Pilgrim-street, E.C. The fourth section, which dealt with lighthouses, buoys, fog-signals, etc., was reported in our columns at the time. The "Minutes of Proceedings" will form valuable works of reference.

Boiler Explosions.—The Scottish Boiler Insurance and Engine Inspection Company, Limited, of 38, Lloyd-street, Manchester, and of Glasgow, have published an illustrated pamphlet dealing with the various causes of boiler explosions. The company issue policies of insurance covering all loss or damage to boilers, buildings, and machinery arising from steam-boiler explosions or collapse

of flues, and also undertake the periodical inspection and indication of steam-engines.

Engineers and Shipbuilders.—The second general meeting of the North-East Coast Institution of Engineers and Shipbuilders will take place to-morrow, the 25th inst., at the Athenæum, Church-street, West Hartlepool. Mr. W. Hok's paper "On a Method of Comparing Steamship Performances and of Estimating Powers and Speeds of Ships" will be discussed, and a paper "On the Dangerous Working Heat of Mild Steel and the Effect of Annealing and Air Cooling," by Mr. Joseph Nodder, will be read.

Lighting in Paris.—A petition has been addressed to the Paris Municipal Council complaining that the Société Belge du Secteur des Champs Elysées do not conform to the regulations under which they work. It is said that a minimum of £20 is charged for making a connection by means of a small branch conductor, whereas the companies in the other Parisian districts only charge £4 for similar work, and often make the connection free, and that, among other matters, the supply of current is suspended from six to eight hours in the 24 hours.

Provisional Orders of the Board of Trade.—Under the title of "Provisional Orders of the Board of Trade," Mr. F. J. Crowther, parliamentary agent, has prepared a manual concerning the various steps necessary in the course of an application to the Board of Trade for provisional orders in the cases of gas and water, tramway, pier and harbour, and electric light undertakings. The manual, which is published by Messrs. Jordan and Sons, of 120, Chancery-lane, W.C., is intended not only for the use of promoters of such orders, but also for their opponents.

The "Medical Battery" Company.—The hearing was resumed on Wednesday at the Marlborough street Police Court of the charges of conspiracy to defraud against Mr. C. B. Harness, the managing director of the Medical Battery Company, Limited; Mr. J. M. M'Cully, physician; Mr. C. B. Hollier, salesman; and Mr. Dudley Towers, *alias* William Robert Sellman, a masseur. Further evidence was given, and the case was again adjourned for a week. Mr. Justice Vaughan Williams, in the Chancery Division of the High Court of Justice, on the same day made a compulsory winding-up order in the case of the "Medical Battery" Company, Limited.

Lighting at Brussels.—The central station was set in operation at the commencement of the present month. The station, which has been constructed and equipped by the India Rubber, Gutta Percha, and Telegraph Company, Limited, of Silvertown, is laid out for the supply of 20,000 16-c.p. lamps. There are at present installed two 500-h p. steam-engines and two dynamos, together with a battery of accumulators capable of serving 5,000 lamps. Additions will be made as required. The current is sent out on the low-pressure system from sub-stations served by feeders. The plant will be in operation from sunset till midnight, after which current will be furnished by the accumulators.

Exhibition at Santiago.—The Department of Science and Art has received through the Foreign Office a despatch from her Majesty's Minister in Chile calling attention to an exhibition which it is proposed to hold next year at Santiago, dealing with mining and metallurgy. The exhibition will be opened in the second fortnight of April, 1894, but the exact date is not yet known. The eight sections of the exhibition will comprise electricity, mining machinery, mechanical preparation of minerals, metallurgy, chemical industries, statistics and plans, and mining and metallurgy products respectively. Applications for space may be made to the Chilian Legation in London.

Artificial Rain.—M. A. Baudouin has presented to the Academie des Sciences a note referring to experiments made to obtain rain by drawing electricity from the clouds by means of a kite. One experiment took place on the 15th October, at about 5.15 p.m. The author then obtained contact with the clouds situated at an estimated distance of 1,300 yards. At that moment a local cloud was noticed, and then several drops of rain fell. As soon as the contact ceased, which was effected by hauling down the kite, the normal state of affairs was resumed at 5.30 p.m. M. Baudouin adds that as far back as 1876 he obtained rain in the same manner on several occasions on the plains of El Meridj, in Tunis.

The Royal Society.—The Royal Society's medals this year have been awarded as follows: The Copley Medal to Sir George Stokes, F.R.S., for researches and discoveries in physical science; a Royal Medal to Prof. Arthur Schuster, F.R.S., for spectroscopic researches and investigations into terrestrial magnetism and disruptive discharge through gases; a second Royal Medal to Prof. H. Marshall Ward for researches into the life history of fungi and schizomycetes; and the Davy Medal to Messrs. J. H. Van 't Hoff and J. A. Le Bel for work in connection with the theory of asymmetric carbon and its bearing on the constitution of optically active carbon compounds. The distribution of the medals will take place at the customary meeting on St. Andrew's Day (30th inst.).

Speed of Propagation of Electricity in a Wire.—M. Blondlot has described some experiments which he undertook to determine the rapidity of propagation of an electric disturbance along a copper wire by means of a method independent of theory; and he gives as follows the results obtained with lines of unequal length: (1) The equality of the values of the speeds obtained (183½ *miles* and 184¾ miles per second) with two lines of different lengths (1,115 yards and 1,973 yards) shows that the propagation movement is tolerably uniform; (2) these figures are perfectly in accordance with those he had previously obtained by another method; (3) the experiments undertaken have the principal advantage of being independent not only from theory, but also even of the existence of electromagnetic oscillations and undulations.

The Phonopore.—The phonopore telegraph, which is in use on several of our railways, and which enables an extra independent message to be sent on the ordinary telegraph wire in either direction at the same time that telegrams are being sent by the ordinary telegraph, has made, we are informed, an additional claim to usefulness by the fact that communication has been maintained by its means under circumstances which rendered the ordinary telegraph altogether useless. The Phonopore Company states that it has recently happened, on four different lines, that though the ordinary telegraph could not work on account of a breakage of the wire, the messages were sent by the phonopore just as if nothing unusual had taken place on the wire. The current by which the phonopore is worked jumped the gap of the breakage, and thus kept up the communication whilst the ordinary telegraph was silent.

Lighting at Edinburgh.—When the members of the Town Council met on Tuesday, Councillor Mortimer moved the disapproval of the minutes of a recent meeting at which it was resolved to light certain portions of the city by electricity. This motion was seconded, but Lord Provost Russell urged the adoption of the minutes, being seconded by Councillor Walker. Councillor Mackenzie, a member of the Electric Lighting Committee, submitted statistics showing the difference in cost between lighting by

gas and electric lighting in the various streets comprised in the proposed area. There would be displaced by the electric light, if it was carried out, 782 gas burners, which cost £1,310. If they deducted from that the office expenses, which represented £68, being 1s. 10d. per burner, the total saving in cost would be £1,242, while 148 or 150 arc lamps would cost £2,960, making an additional cost of £1,718. But there was a patent which was being applied to arc lamps, and which would, Prof. Kennedy said, permit them to turn off the light half-way, and that would save, perhaps, from £600 to £700 per annum. Some further discussion ensued, and the minutes were adopted.

Dangers of Coal Gas.—With reference to the note given in another column concerning an explosion at Manchester, an electrical contractor writes as follows to a provincial contemporary, which published the statement in sensational terms: "As this paragraph is likely to mislead your non-technical readers, and consequently damage us contractors, may I be permitted to make a few observations regarding the paragraph referred to? In all large towns, such as Manchester, there is a considerable leakage of both sewer and coal gas. These gases find their way into the pipes and culverts of the electric system, and once there, and mixed with the proper proportion of air, form a highly explosive mixture. The slightest spark between the electric cables then explodes the mixture. To blame electricity is hardly fair. Why not head the paragraph 'Dangers of Coal or Sewer Gas'? If a miner's safety lamp ignites an accumulation of fire-damp in a coal-pit, would anyone call it the 'Dangers of Using Safety Lamps'? I think not. There is no mention of gas in the paragraph. My reason for troubling you with this letter is that the paragraph is likely to do us contractors a good deal of harm by frightening our probable customers." We fully agree with the contractor's remarks.

Liquid Air.—In connection with the forthcoming lectures at the Royal Institution on "Air, Gaseous and Liquid," it may be mentioned that Prof. Dewar has successfully conveyed a considerable quantity of liquid air from London to Cambridge. The liquid air was carried in a double glass flask, the space between the inner and outer flask containing nothing but extremely attenuated mercurial vapour, together with a little liquid mercury. On pouring liquid air into the inner flask, its outer surface is rapidly covered with a mercurial film of extreme thinness, forming a reflecting surface highly impervious to radiant heat. As soon as this is formed, the whole apparatus is packed in solid carbonic acid, which at once freezes the liquid mercury, arrests the deposit upon the mirror, reduces the mercurial vapour to an infinitesimal quantity, forms an almost perfect vacuum, and supplies an envelope 80deg. below zero. Thus protected, the liquid air reached Cambridge with only a trifling loss of bulk, notwithstanding the incessant jolting of the railway. The protective power of the high vacuum and the mercurial mirror will be better appreciated if it be borne in mind that the difference of temperature between liquid air and solid carbonic acid is the same as between ice and boiling water.

The Subsidisation of the French Cable.—"It is not often," remarks the *Pall Mall Gazette* in yesterday's issue, "that questions of what may be called 'foreign policy' disturb the peace of the Australian Governments. Lately, however, they have been paying a considerable amount of attention to extra-colonial matters. First, as we have already noted, there has been a good deal of embittered controversy over the action of the New South Wales and Queensland Governments in subsidising the French cable from Australia to New Caledonia, constructed avowedly as the first link in a chain of communication which is to be extended to Canada under the same auspices. Lord Ripon has taken an unusually Imperial view of the matter, and has made no bones of expressing his concurrence with the protest which emanated from the Victorian Premier on the subject. When the mail just to hand left, hot controversy was raging over the publication in the Melbourne press, of Lord Ripon's despatch communicating the views of Mr. Gladstone's administration on the unpatriotic action of the two Eastern colonies in subsidising the further intrusion of France into a sphere which only a little time back they were frantically proclaiming to be the sole domain of the Australian branch of the British Empire."

Artificial Diamonds.—Reference was already made to this subject a little time ago in connection with the experiments of M. Moissan. To obtain the powerful pressure which he judged requisite to the formation of the diamond, M. Moissan conceived the idea of utilising the property that certain bodies possess of increasing their volume when cooling from a liquid to a solid state. He placed silver and charcoal of sugar in an electric furnace and fused the metal to a state of ebullition; a certain quantity of carbon was thus absorbed by the metal. The mass was then thrown into water, and at once formed a shell of solid silver. When this was withdrawn from the water and allowed to cool slowly, the pressure of the kernel of molten silver contained in the exterior shell, which expanded in the process of cooling, precipitated the carbon in the form of microscopic black diamonds. Following this experiment, M. Moissan enclosed in a cylinder of soft iron a certain quantity of charcoal of sugar, and plunged it into a bath of liquid iron, placed in an electric furnace. Withdrawing the crucible from the furnace, he plunged it in water and allowed the mass, as soon as the exterior shell was formed, to cool gradually. The result was the production of genuine diamonds, microscopic indeed, but still true diamonds.

Electricity Applied to Domestic Purposes.—A lecture on "Electricity as Applied to Domestic Purposes" was recently delivered at Westwood House, West-hill, Upper Sydenham, by Mr. G. Offor, M.I.E.E., managing director of the Crystal Palace District Electric Supply Company, Limited. The lecture has now been printed in the form of a pamphlet, a copy of which has been forwarded to us by the author. In dealing with the district covered by the company's parliamentary powers, Mr. Offor pointed out that the area lay in the counties of Kent and Surrey, in the parishes of Lambeth and Camberwell, in the districts of Lewisham and Beckenham Board of Works, the borough of Croydon, and to a large extent in the county of London. He did not think the company would ever come under the compulsory sale powers of the Act of Parliament, as it would involve a combination of the local authorities of the districts mentioned to deal with the matter, which he regarded as practically impossible. The lecturer briefly referred to the system of supply adopted by the company, and mentioned cases, on the one hand, where the electric light had proved to be cheaper than gas lighting, and, on the other, where the cost had been about the same as illumination by gas. He next referred to and exhibited electric kettles, frying and stew pans, grills, flatirons, cigar-lighters, small electromotors, and concluded by giving particulars of dividend-paying electric light companies, and of the number of lamps supplied from their respective stations.

Electrical Conductivity and Specific Resistance of Metals.—The experiments of Profs. Dewar and Fleming on the electrical conductivity and specific resistance of metals at extremely low temperatures have been continued

since the publication of the initial paper last year, and further results have recently appeared in the *Philosophical Magazine*. The object of these further experiments was to determine the specific electrical resistance of metals and alloys over a wide range of temperature, from about 200deg. C. to nearly – 200deg. C., the temperature of liquid oxygen. A large number of pure metals were subjected to test, including gold, silver, platinum, copper, aluminium, iron, tin, nickel, zinc, cadmium, lead, magnesium, palladium, and thallium. From the tables published it appears that the order of conductivity of these metals is very different at low temperature to what it is in the higher ranges. At the lowest temperature, reached by means of liquid oxygen and a vacuum as well, copper is the best conductor, instead of silver, and there seems to be a real or fortuitous connection between the sonorous properties of the metals and their conductivity. Thus gold, silver, aluminium, and copper are all good conductors, while lead, zinc, tin, palladium, and thallium are inferior. The experiments tend to confirm the theory on which they were originally based—viz., that at absolutely zero temperature the specific resistance of pure metals would become nil, and that most unattainable of rareties, a perfect conductor, would be actually realised. The observations are to be continued into even lower temperatures in a further course of experiments.

Influence of a Three-Wire System on Telephone Wires.—In a paper given in the *Elektrotechnische Zeitschrift* of the 17th inst., M. Th. Erhard, of Altona, deals with the influence upon telegraph and telephone wires of a three-wire system of distribution. The author states that as far as disturbances caused in telegraph wires through strong current installations is concerned, the post and telegraph authorities admit that such interruptions are accounted for by extraordinary events, and that therefore they are almost left out of consideration. The case is similar with disturbances in the working of telephone lines in so far as understanding by means of the telephone is concerned. The author enters into details regarding various interruptions at Altona. He concludes that in regard to the falling down of indicator switches in the telephone exchanges, the bare middle wire rather brings about fewer disturbances in telephone working than the insulated wire; but when the worst enemy of telephone wires, the constant passage of current by which it is impossible to replace the indicator switches, is considered, the advantages of the bare middle conductor over the insulated central wire considerably preponderate. As to disturbances in telephone working through the impossibility of making connections with subscribers, the bare copper conductor is not more disadvantageous than the one that is insulated. The interruptions in telephone circuits caused by strong currents are principally insignificant in relation to the other disturbances occurring in telephone working. The observations hitherto made have in no single case led to the apprehension of greater disturbances in telephone circuits, and Mr. Erhard therefore believes that by mutual goodwill conductors carrying both strong and feeble currents can be placed near one another without troubling about either a bare or insulated central conductor. One of the great advantages of the bare middle conductor is that the insulation of house installations can be better maintained than with an insulated middle wire, and greater security in telephone working can thereby be obtained. Recent insulation measurements in house installations of from one to two years' standing showed insulation resistances of not less than 100,000 ohms.

Extensions at the Bradford Station.—The extensions which have been in course of being made for some months past at the central station of the Corporation are now approaching completion, and the output of the works will shortly be increased to the extent of 30 per cent. The alterations have been carried out under the supervision of Mr. Shoolbred, the engineer retained by the Gas and Electricity Supply Committee. The station is situated near the bottom of Bolton-road, with a frontage to that thoroughfare, and overlooking at the back the Jollity Theatre and Canal-road. The length of the frontage is 165ft., and the width of the plot of ground is upwards of 70ft. Of the side nearest Canal-road, a length of 105ft. is occupied by the engine-house, a single-storeyed building 22ft. wide, with a lodge opening towards Canal-road at each end. Side-by-side with the engine-house is a building precisely similar in construction and dimensions. From the middle of this building rises a tall chimney, with the boiler-house at the further end of the building and the storage-battery room at the town end. The alterations include the erection of a building 165ft. in length, 22ft. in width, and two storeys in height along the whole frontage to Bolton-road. The basement or first storey is used, so far as the ends are concerned, for the storage of coal, and fuel can be shot direct from Bolton-road. The intermediate space has been utilised for the laying down of boilers and the erection of a smoke economiser. When the Gas and Electricity Supply Committee deem it advisable to spend more money on what has thus far proved a most profitable investment, the works will be further extended by raising the engine-house and the intermediate building to the height of the newly-erected one. The cost of the new building will be from £6,000 to £7,000. The principal additions to the plant consist of two Willans engines, each of 200 i.h.p. There were previously seven engines, with a total of 1,200 i.h.p., and the existing engine-house will provide space for two new engines of the size of the latest additions. There are four Lancashire boilers on the premises, each 20ft. in length by 7ft. in diameter, and one of the Babcock and Wilcox type. The storage-battery room has proved of great utility, as it provides the supply of electricity for 10 hours out of the 24.

Rapid Transit.—In the course of an article in a recent issue of the *St. James's Gazette*, a correspondent says: "Travelling by train at 150 miles an hour is by no means slow work, but there are certain electrical engineers on the Continent who say that such a speed is quite possible. They have gone further than this. So sanguine are they of the truth of their assertion that they have accepted a contract to build electric motors which shall run at this speed on a line to be laid between Brussels and Berlin. It seems at first sight a rather big jump from 60 or 70 miles an hour—the highest speed that has been hitherto practicable on the best of modern railroads—to a speed of more than double that velocity. But to the electrician most things are possible—at all events, on paper. Indeed, electrical engineers have long been aware that if once they can overcome one or two little difficulties in the system, they will be able to produce electromotors of a speed that will make even the Brussels-Berlin scheme seem very slow travelling. The promoters of the new line on the Continent say they have found out the way, but whether they will succeed or not it is impossible to say until a trial has been made. If a storage battery of very light construction be someday discovered, high speeds may yet be possible by this system, and that is all that can be said on the matter. The engineers of the Brussels to Berlin railway have wisely owned their inability to cope with the difficulties of weight, which are the chief drawbacks to the storage system. Their idea is to feed the motors with current as they speed along the line. This can be done by using one or both of the rails as conductors for the current. There must be a

central generating station situated at least at every 10 miles along the route, where electricity is produced and supplied to the rails. The moment the current enters the latter it is practically available at any point, for the time occupied in travelling their length is inappreciable. It it be inconvenient to use the rails as conductors, the current can be collected equally well from an independent metal bar fixed all the way between the lines, as is done in the case of the South London Electric Railway. Although there is little or no limit to the distance electricity can travel along a conductor, its strength very soon begins to diminish; and unless the strength can be maintained uniformly the motor will not give satisfaction. Again, where the current is conveyed by rails there will always be a leakage to 'earth'; and this will happen no matter how carefully the rails may be insulated. In wet weather these leakages would render the railway practically unusable, for damp is an excellent conductor. If it were possible to keep the pressure uniform all the way and to avoid any leakage whatever, then 150—or, for the matter of that, 500—miles an hour would be perfectly practicable."

Hedgehog Transformers and Condensers.—In a paper read before the American Institute of Electrical Engineers, Messrs. F. Bedell, K. B. Miller, and G. F Wagner dealt with this subject. The first part of the paper formed a description of apparatus and measurement. The method of instantaneous contact was employed for obtaining the E.M.F. at various points of the phase, for which purpose the contact employed consisted of a needle attached to a revolving disc which cut through a fine stream of water at every revolution, and the potential difference was obtained by means of a multicellular voltmeter with a pneumatic damping arrangement, devised by Prof. Ryan. The Hedgehog transformer primary consisted of 1,426 turns of wire 0·072in. in diameter, arranged in 12 layers. Its resistance was 2·748 ohms, and its weight 29lb. The secondary consisted of 73 turns of cable composed of 19 strand of 0 058in. wire, with a resistance of ·0149 ohm, and weighing 12 5lb. The transformer was designed for 1,000 volts at 130 periods. Experiments show that at no load the lag of the primary current behind the primary E.M.F. is almost 90deg., which is greatly in excess of the lag shown by similar experiments upon transformers with closed magnetic circuits. The secondary E.M.F. at no load is almost opposite in phase to the primary E.M.F.—that is, almost 180deg behind it. With increased load the lag increased slightly, due to increased leakage. The curve for efficiency rises very rapidly as the load increases, reaching 90deg. at about one-eighth of full load. From quarter load it is nearly constant, rising to 96 6 per cent. at two-thirds load. It remains practically constant until full load is reached, and then falls off slightly on verload. The all day efficiency calculated on a basis of five hours at full load out of 24 hours is 91 8 per cent. There is a fall of about 2 5 volts in the secondary between no load and full load. Tests were then made with Stanley condensers in circuit and readings taken for determining the primary E.M.F., secondary E.M.F., primary and line current. The results of three runs are given in the following table, showing clearly the effect of the condenser in diminishing the line current, especially at no load:

Lamps in secondary.	Primary current.	Line current.
0	95	·187
15	1·24	867
45	3·07	2·73

At no load the line current is seen to be less than one-fifth of the primary current, or the value it would have if the condensers were absent; even under full load the reduction is considerable. As the results of these tests, the authors conclude the transformer upon which the investigation was made possesses two valuable features—high efficiency and good regulation. The experiments with the condensers demonstrate the practicability of their use to diminish the line current in transformer circuits, and points to their more extended use, as their manufacture is perfected and cheapened, not only in this, but also in other systems of alternating-current distribution

Electric Shot-Firing in Coal Mines.—A paper on this subject was read at Wigan recently by Mr. Peter Houghton before the Lancashire Association of Colliery Under Managers. The author said that he did not intend to treat the subject from a scientific point of view, but more from a practical one. He remarked that amongst the number of modern improvements in our mines it was found, owing no doubt to the large number of lives that had been lost by explosions and the introduction of the high-safety explosives, the question of electric shot-firing had made very rapid strides, and was now being pushed forward by her Majesty's inspectors of coal mines as the only safe method by which the safety explosives now in use could be fired. They all knew that Mr. Henry Hall, of their own district, strongly advocated the use of safety explosives fired by electricity in preference to gunpowder. The firing of a charge of explosive through the agency of a slow-burning fuse, though still very extensively practised in mining, presented such decided disadvantages in regard of uncertainty, and in some cases of danger, when compared with the firing by electricity, that it was not surprising to find what rapid strides the question of electric firing had made. The object of electrical firing was one of safety, though the mining fuse patented by Bickford effected an enormous improvement in the firing of charges in mines; yet there was little doubt that accidents in mining would be considerably reduced in number if electrical blasting were more frequently employed, especially in dangerous mines, instead of the uncertain system of firing by slow-burning fuse. Many men had met their doom through going up to a shot in the false belief that the fuse had burned out or become extinguished. In some instances the fuse had been burning for hours; also, explosive mixtures had been ignited and proved fatal to life, owing to the spit of the fuse when touched with the heated wire. With electric lighting the simplest precautions sufficed to ensure absolute safety, and in no case where it was necessary that safety explosives had to be used ought they to be fired by any other agency than electricity, because it was not wisdom to adopt a safe explosive and use for its ignition an unsafe means, thereby destroying, to a certain extent, its safety as an explosive. Perhaps, in no other district in this country had the use of the safety explosives and the firing by electricity become more general than in that district. The author went on to describe high and low tension exploders, and the methods of firing the detonators. He submitted that they ought to make themselves thoroughly acquainted with all things introduced for the safe working of mines. He contended that, owing to electric firing having been placed in the hands of persons not previously having had any knowledge of either the explosive detonators or the electric appliances for firing purposes, accidents had happened, not altogether through carelessness, but more from ignorance of those things which had fallen in their hands to use. But as knowledge was gained of what a detonator consisted of, and its danger when tampered with, so would men become more cautious when a miss-fire happened to regain the detonator, and he believed accidents from this cause would be few and far between. The author concluded by considering more fully the causes of miss-fires from electric firing.

WILLIAM GEIPEL.

Wm. Geipel, M.I.E.E., was born in 1860, and educated at Bristol Grammar School and at the College of Physical Science, Newcastle-on-Tyne. He passed the Oxford local examination in 1876, and the City Guilds examination in electric lighting and engineering in 1882, in both of which he obtained first-class honours. Mr. Geipel served a four years' apprenticeship in the workshops and drawing offices as a mechanical engineer, at the well known marine engine works of Messrs. T. Richardson and Sons, of Hartlepool, and was also six months at Hebburn Collieries, county Durham, studying mining engineering. He entered the service of the Anglo-American Brush Corporation in 1882. Shortly afterwards he was appointed assistant manager at their dynamo works in Borough-road. In 1884 he was sent by them to Edinburgh to superintend the lighting of the Forestry Exhibition, which was exclusively carried out by the corporation under his supervision to the entire satisfaction of the committee. Subsequently, Mr. Geipel negotiated and carried out for the Brush Company a large number of electric light installations in England and Scotland, and opened branch offices in Edinburgh and Glasgow, which were under his charge, as the company's superintendent for Scotland, up to 1889. Upon the formation of the Scottish Electric Supply Company, Mr. Geipel became one of the directors. In 1889, owing to the rapid development of their business, the Brush Company selected Mr. Geipel as their central-station engineer, in which capacity he controls the designing, working, and equipment of the Brush Company's central stations. For two years previous to his leaving Edinburgh he held an appointment at the new Heriot-Watt College as lecturer in electric engineering. Mr. Geipel is an occasional contributor to the technical Press and to the *Transactions* of the engineering societies.

INSTITUTION OF ELECTRICAL ENGINEERS.

The Institution of Electrical Engineers held their fifth annual dinner on Wednesday night at the Freemasons' Tavern, when a company of upwards of 170 gentlemen sat down under the presidency of Mr. W. H. Preece. The following were present:

Adams, Mr.
Albright, Mr.
Allen, Mr. A. W.
Anderson, Mr.
Anderson, Dr. W.
Andron, Mr.
Armstrong, Mr.
Armstrong, Dr.

The PRESIDENT, after dinner, and after the toast of "The Queen" had been honoured, proposed "The Learned Societies."

Sir J. CRICHTON BROWNE, responding, said the learned societies were all standing tip-toe, eager to see what electrical engineers were going to do next. They were full of gratitude and admiration for the splendid achievements of electrical engineers in recent years, and they had a lively sense of favours to come. They had festooned our homes with beautified glow-worms; they had stretched our ears, not in any asinine sense, so that they extended all over the town, and even as far as Paris; they had kept us in hourly and sympathetic vibration with everything that was going on in the uttermost quarters of the world; they whirled us about; they elevated them and depressed them; they welded our metals like the gnomes; they performed chemical transmutations like the alchemists; and they even treated us when we were ill, like the Royal College of Physicians. They had vastly increased the comforts and convenience of modern life; they had added enormously to the means of human intercourse; they had afforded invaluable assistance to the students and investigators in every department of science. To find a parallel to their splendid achievements of recent years and to the expectations they had created, it would be necessary to go back to the sixteenth century, when Columbus and his followers, by their discoveries in the

New World, created great hope and expectation; and he was certain that when the history of Queen Victoria's reign came to be written there would be no more brilliant chapter in that history than the one which recorded the exploits of electrical science.

Prof. RUCKER, in his reply, dealt very largely with the connection between theory and practice, and thought the practical man did not always give sufficient credit to the theorist, and would be glad to see a closer intimacy between the various learned societies.

Prof. W. E. AYRTON, in one of his inimitable humorous speeches, gave the toast of "The Engineering Societies," to which Sir F. BRAMWELL replied, pointing out that the year of his birth corresponded with the year of the birth of the Institution of Civil Engineers, and that the framers of the rules of that institution had very wide and broad views which had not and would not be departed from. The Institution of Civil Engineers held out the right hand of fellowship to all engineering societies, placing so far as possible the rooms and resources of the institution at their service.

Mr. LATIMER CLARK proposed "The Guests," informing those present that they had with them one of their honorary members, Mr. Jacob Brett, who was connected with the early work of submarine telegraphy, in the laying of the Dover-Calais cable in 1851, and who in those early days suggested an Atlantic cable.

Mr. A. MORLEY, acknowledging the toast of "The Guests," proposed by Mr. LATIMER CLARK, expressed the opinion that no commercial undertaking, certainly no department of the State, was more dependent upon or interested in the successful development of electricity than that branch of the service with which the President was connected, and over which he himself had the honour to preside. It was common knowledge that the success of our telegraph and telephone systems was dependent upon the successful utilisation of electrical currents, and he did not think he claimed too much when he said, with regard to the first of those services, that we had at least taken the foremost place among the nations of the world, even if we were not entitled to claim that we had surpassed all other nations on both sides of the Atlantic, and that we had provided a service which was superior to that of any other country. A series of almost unprecedented storms had lately been experienced, and he was glad to be able to report that the telegraphic service of the country had almost without exception been uninterrupted by those serious disturbances. It was not so with some of our continental competitors, and two days ago, speaking telegraphically, we had once again absorbed Calais within the empire of Great Britain, because all telegraphic communication with Calais was for a time entirely suspended, except by the wire which connected Calais with London. He did not know that he could say so much with regard to our telephone system, but he had very little doubt that the time was not far distant when that system would be equal, if not superior, to the telephone of any other country. The right hon. gentleman referred to the benefits which had resulted from the introduction of the electric light in the General Post Office, and mentioned that trials were now being made there with an electrical machine which defaced stamps at the rate of 560 or 580 a minute, as compared with 150 a minute defaced by the old method.

Mr. MUNDELLA proposed the toast of the evening, "The Institution of Electrical Engineers." He took occasion to mention that the excellent work done by the Electrical Standards Committee had been approved generally by electricians throughout the world. France, Germany, and the United States were prepared to adopt them, and he was so much encouraged by all he heard of the prospects of an international arrangement that it would shortly be his duty to submit an order in Council to her Majesty adopting the electrical standards as the standards for this country, and he hoped for the civilised world. They were making progress in this country with respect to electric lighting, for whereas when he addressed them last year there were only 26 local authorities which had obtained orders approved by the Board of Trade, now there were 46 local authorities in that position and 62 companies. He acknowledged the indebtedness of the Board of Trade to the Institution, and cordially desired the development and extension of its operations. There was room for a good deal to be done in England, for example, in the way of extending electric railways. Hitherto progress in this direction was slow, but he read the title of the draft rules to be considered by the Board of Trade (given in full elsewhere in this issue), which before agreeing to he would probably submit to the Council of the Institution for suggestions, and he hoped that the way would thus be paved for more rapid progress.

The PRESIDENT, in reply, said it had been his lucky fortune to have been instrumental in introducing the Institution to nearly all the wonderful developments of electricity that had so singularly distinguished this last half of this Victorian age, and this was greatly owing to his frequent visits to that energising country, the United States of America. In only one branch of electrical industry could we compare favourably with our American cousins, and that was in telegraphy. We were certainly ahead of them in that field, but in every other branch, especially telephony, we were behind in material progress, and we had very much indeed to learn from their rapid advances and their practical ways. But our advance, though slow, was sure, and he was not quite sure that we should not win in the long run. He touched upon the growth of electric railways and the electric light, and claimed that the electric light was the poor man's light. The trouble experienced was not that it was too dear, but that it was too cheap. The growth of the Institution of Electrical Engineers was shown by the fact that the total number of members of all classes on January 1, 1873, was 352, while at the present time it was 2,260, and the average number of members elected annually during the last six years had been 225. The Institution dealt with the present, and its object was to collect facts, to circulate truth, to cement friendship, and to provide for its scattered brotherhood a local habitation and a name.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.

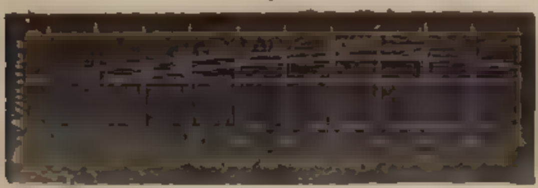
BY PROF. GEORGE FORBES, F.R.SS. (L. AND E.), MEMBER.

(*Continued from page 473.*)

It will be well at this point to say something about the frequency which is required to prevent the arc and incandescent lamps from flickering. I have made a number of experiments on these points, and my conclusions are as follows: A 16 c.p. 50 volt incandescent lamp shows a flickering almost up to 25 periods per second, at which frequency the flickering ceases when at its normal brightness, but if pushed to an excess of incandescence, the flickering was just perceptible up to 27 or 28 periods. I believe that a 100 volt 16 c.p. lamp shows a perceptible flicker up to 28 periods; but I may mention that this flicker is not nearly so serious or perceptible as that which frequently arises from the employment of certain types of engines, especially single-acting high-speed engines, when sufficient flywheel momentum is not provided. As a case in point, I would mention the lighting in the Holland House, one of the best hotels in New York, where, to an experienced eye, the flicker of the lights in the large dining-room from this cause is very objectionable. The thinner the filament, the more liability is there to such a flickering. I have lately examined the thick filament lamps to which the name of "Bernstein" lamps has been given, which consume six to ten amperes at low voltage. It takes so long a time for the incandescence to die out when the current is stopped, that I have little doubt about their being able to work without any perceptible flickering at so low a frequency as even 16 periods per second. I have also made some experiments of a similar nature on arc lamps at low frequencies. At 37½ periods per second there was a very bad flickering, and this was most noticeable when looking at a piece of white paper illuminated by the naked light, or when looking at an opal shade put on the lamp. At 40 periods it was still bad. Neither at this speed, nor at the previous one, was there any serious noise but at 40 periods the noise could be perceived by putting a glass globe over the lamp resting on the metal framework directly. At 41·7 periods there was just enough flickering to be objectionable; at 45 periods it was just possible to notice it on a printed page held close to the lamp, but it was not visible when reading at a distance of 10ft. At 50 periods the only means of detecting anything of the sort was by looking directly at the arc; nothing was seen when reading a book either with the opal shade on or off. At this frequency the noise became much more perceptible, especially with a long arc about one eighth of an inch. On reducing the length of the arc to one sixteenth of an inch the noise was much less. In all these experiments the consumption of energy was at the rate of 26 volts and 14·2 amperes at the lamp terminals. The best cored carbons of Siemens and Halske were used.

An objection has been raised to the use of low frequency owing to the fact that a periodical twisting strain is given to the shaft of the dynamo, but this objection disappears almost entirely when we are dealing with a machine generating two phases.

It follows, therefore, that for arc and incandescent lighting at a very low frequency it becomes necessary to use alternating current motor generators, or else to use something of the character of a commutating machine to convert into continuous current. Such machines as those exhibited by Schuckert at Frankfort in 1891 are useful up to a certain extent, but they are expensive, and comparatively inefficient, as their only function is to commutate the current—an operation which ought not to involve any significant loss. At the present moment a good commutator for the alternating current is not upon the market, but the matter is of such prime importance that I feel confident that much will be done in this direction. In fact, I have seen enough with my own eyes to have no fear about our being able to generate continuous current from the two-phase alternating current without serious loss, and with very inexpensive machinery. If, however, the object of our work was mainly, or even to a considerable extent, to provide the means of lighting towns by arc and incandescent lamps, I should have hesitated to recommend a reduction in frequency below 42 periods per second, such as is used by Ganz and Co., and which is operated so successfully at Rome and Tivoli, and at a very large number of other places on the Continent. The officers of the company and myself considered this matter most carefully, and, looking at the purposes for which our machinery is being set up, we felt sure that the proportion of electricity which would be used for lighting purposes would not be large, and that we must look upon our whole plant as a power producing and distributing plant, and that our object must be to distribute power in the most efficient and economical manner. This being the case, we agreed that it was desirable to lower the frequency so far as the mechanical conditions of the problem would allow. The lowest frequency which had been offered to us by the manufacturers was a very beautiful design of a machine at a frequency of 20 periods per second. This machine had admirable qualities, but was in some points not exactly adapted to the requirements of the situation, as developed by the selection of a special design for the turbine.



Tests made of a Three Phase Motor at 41 Complete Periods per Second and at [illegible], at 66 Periods per Second. [illegible]

I have myself made several trials of designs at very low frequencies, even as low as 8½ periods per second and for this frequency I prepared drawings of a machine which, though by no means perfect, shows a possibility of being worked into a sound machine of good mechanical construction; but further considerations led me entirely to modify the design of the machine, and eventually I arrived at the conclusion that, both from the point of view of design of the dynamo, and also for suitability of applying the current, 16 periods per second was probably as good as could be obtained. The manufacturers to whom the contract has been given were anxious to use a lower induction in the iron of the machine than that which I would have preferred, and this rendered the machine at 16 periods per second heavier than could be supported by the hydraulic piston which supports the whole weight of the turbine, vertical shaft, and revolving part of the dynamo. Consequently we have made a compromise, and are going to build our first three dynamos with a frequency of 25 periods per second. In concluding my remarks upon low frequency, I must again repeat that, from a purely practical and commercial point of view, one of the great advantages lies in the fact that for any special purpose for which a motor is required any ordinary direct-current motor may be altered so as to act as a synchronising alternating motor at a very small expenditure of time and money.

Electromotive Force.

The question of selecting a suitable electric pressure for working to Buffalo, and also for local purposes, is of some importance. Generally speaking, it is desirable to use as high an electric pressure on the line as is consistent with safe and continuous working, as this effects a great saving in the amount of copper used on the line. In the first report, founded on insufficient data, which I wrote more than three years ago for the Cataract Construction Company, I recommended that 2,000 volts should be used in the neighbourhood, and that the pressure should be raised by means of transformers for the more distant transmission. But the greater portion of our work in the immediate future will have the character of distant transmission. In most of the tenders which were submitted to us the cost of transformers were almost as much as that of dynamos, in some it was more, so that the use of a step-up transformer for distant transmission meant almost double the cost of generating the current. I hold the view that a pressure of even 20,000 volts can be generated as safely in the dynamo machine itself as in the transformers, and that if we used 20,000 volts for the local work as well as for Buffalo we should not be incurring the additional expense and losses of a step-up transformer, while we should be saving enormously in the cost of copper. Unfortunately, American manufacturers have never supplied alternating current dynamos at a higher pressure than 2,000 volts, and they are not practically acquainted with the experiences which have been gained in Europe at extra high pressures. Most of the manufacturers declared their inability positively under any conditions to go above 2,500 volts, although some of their engineers were willing to go as far as 5,000 volts. This, however, would have been no material gain to us; and the consequence is that to meet the views of the manufacturers in our preliminary work—that is to say, in the construction of the first three dynamos for our power house—there will be only of such electrical pressure as they are accustomed to deal with. We shall therefore be using dynamos generating current at 2,000 volts, and employing step-up transformers for the extra high pressure. This may possibly render it desirable in our first work not to use the extra high pressure for local purposes. Besides the actual cost of the conductors, a very serious matter arises when we are dealing with the large currents due to comparatively low electric pressure. I refer to the large quantity of copper which has to be put into the conductors. Working at 2,000 volts, each phase of each of our generators will give nearly 1,000 amperes, without considering the effects of retardation of phase, which will increase the current by quite a perceptible amount. So that, to put in the most economical section, will require 3 square inches for each conductor or 12 square inches of copper for each 5,000 h.p. dynamo, or 36 square inches section of copper for the 15,000 h.p. which is now being supplied. When we remember that even with low frequency the question of skin resistance comes into play when the conductors have a large diameter, it is obvious that we are introducing serious troubles, and if a subway were to be made to carry these conductors it would require to be of very great dimensions. For these reasons I am still anxious to see the extra high pressure used even for the factories within a distance of a mile. The uniformity of the system would undoubtedly be of great benefit to us if we could generate the whole current for all purposes at the same extra high electric pressure, but, as I have stated, we were obliged to content ourselves with a somewhat less perfect arrangement than would be adopted if we were dealing with the utilisation of a waterfall in Europe.

I wish to lay stress on the importance which I have considered to lie in the fact of having a perfectly uniform system with interchangeable dynamos. Many engineers to whom I have talked have suggested the use of special dynamos at different pressures for special purposes; but if we had a special dynamo for arc lighting, and another for incandescent lighting, a third for street railways, another for electro deposition, and so on, the possibility of interchanging dynamos would disappear and the whole system would be much more complicated to work.

I wish now to make a few remarks about the insulation which it has been customary to put upon dynamos and transformers which were to be used with high electric pressure. Many persons who have not given sufficient attention to the subject seem to be inclined to believe that there is something mysterious about the tendency of electricity in a dynamo or transformer to break through the insulation, and which prevents them from being subject to the ordinary laws of electricity. Thus, when building a dynamo for 2,000 volts a thickness of insulation is given which would stand a test of more than 100,000 volts without breaking down, and it has been found from the ordinary methods of using the plant that if something of this sort is not done the insulation will break down. I wish to point out that the reason for this lies in the fact, not that the insulation breaks down with 2,000 volts, but that in a 2,000-volt system as generally used E.M.F.'s are occasionally generated amounting to 100,000 volts or more. These abnormal rises in electric pressure are chiefly due to the resonant effect, which has received so much attention of late years, and may be caused by the sudden breaking of the circuit of the dynamo. If these causes of excess be avoided, the electric pressure will never rise above the working pressure, and the insulation will never break down, even though its thickness be only little more than sufficient to stand a test at the working pressure. Dr. Fleming has shown us how to kill the resonant effect, and such a phenomenon never appears now at Deptford. This trouble may also be avoided by having as little capacity on the line as possible, especially when combined with low frequency. As to the cause of trouble mentioned above, I hold that it is a piece of culpable ignorance, ruinous to the machinery, if anyone should ever on a large power circuit with alternating current, suddenly break the circuit while current is passing. This practice is quite unnecessary, and has given rise to a large proportion of the breakdowns of alternating current machinery.

Parallel Working.

Engineers in America have had no experience in actual commercial conditions of parallel working with alternators. This is partly because the machines which have been made in that country do not work so well as some others in parallel. In the case of the transmission from Niagara Falls my opinion is that parallel working will give the best results. If this arrangement were not adopted it is obvious that when the dynamos are loaded up as much as possible they could never be all fully loaded. It is also quite obvious that if our conductors are to be carried through subways, the space required becomes quite excessive unless we adopt parallel working. The complete success of parallel working between Tivoli and Rome left no doubt as to the feasibility, besides the desirability of adopting parallel working. The reduction in frequency which we have made assists very considerably in this result, and it says much for the American manufacturer who has received the contract that, although parallel working with

multiphase machines has not been adopted in the past, he is ready to guarantee the performance in this respect of the machines which are to be built for us.

The rules which govern the construction of machines which shall work well in parallel are not very clearly understood. The only fact which has been perfectly established in practice is that the lower the frequency the more efficient and sure is the parallel working. It certainly depends to some extent upon the amount of self induction and the amount of mechanical momentum in the machines. It is also certain that if the self induction of the machines is too high they will not work well in parallel. Of all machines which have been constructed, those which work the best in parallel appear to be those of Ganz and Co., Mordey, and Elwell Parker, but there are many others which do extremely well. It is, at present, not possible to state exactly the conditions which are necessary, but I may say that generally a machine with a stiff magnetic field works better than one where the iron is far below magnetic saturation. In judging whether a machine of a particular type will or will not work in parallel, I think one must be generally guided largely by one's own personal experience in the matter, combined with a knowledge of the effects of self-induction, mechanical momentum, and magnetic saturation as deduced from theoretical considerations. I do not think that anyone who knows anything of the working of the Tivoli Rome plant would for a moment hesitate in saying that on a large and important station like that at Niagara Falls parallel working is essential; and this is the opinion of Prof. Mengarini, who has so ably directed the works at Rome.

Motors.

Under this section it may be as well to discuss some of the different purposes for which the electric current will be required. With regard to arc and incandescent lighting, if the frequency be high enough, the current can be used directly for this purpose; although most people would prefer that, in the case of arc lighting, the current should be commutated or converted in some manner so as to give a continuous current. That this is unnecessary, however, is amply proved by the perfect success of the arc lighting by alternating currents in Rome, and many other large cities, especially those which have been established by Messrs. Ganz and Co. At the present time one of the largest applications of electricity in the United States is for street railways, which require a continuous current. Another similar purpose which we shall have to consider is the application to canal boats, since it is intended to work the Erie Canal by electricity. This canal starts from the Niagara River, and reaches the Hudson River at Albany, 350 miles distant. For these purposes some sort of commutator or motor transformer will be desirable. Some of the first work which will be done is the supply of much direct current at 150 volts for the production of aluminium. This also requires the continuous current, and similar means must be used for obtaining it. Among the large class of mills which will be established at Niagara Falls, one of the most important kind is wood pulp mills, one of which is already working on our land, and will be the first to receive water power from our canal. This type of mill uses many thousands of horse-power, and is worked continuously day and night. In this feature it resembles, probably, a large number of the mills which will take advantage of the cheap power at Niagara Falls. Such mills are working continuously day and night, and do not require to be ever stopped or reversed. This is an important class of work in our case, because current can be supplied to such mills by means of synchronising alternators whose efficiency is extremely high, and this may perhaps be done in some cases without transformers. We require also to consider the case of small motors for use in shops, and for elevators, cranes, and a large number of other purposes. In this type of motor frequent stoppages and reversals are necessary. Hitherto, direct-current motors have generally been employed for this latter purpose, but the rotating-phase induction motors are distinctly suitable, and when these have been fully developed they will probably be largely used for this purpose. The commutated current is a thing which is sure to be in common use before long, and although our arrangements at Niagara Falls are perfectly complete without a machine for this purpose, still its employment has been considered by us, and the probability of its future use has influenced our judgment in some points. There are so many purposes for which the direct current is most convenient, that people would generally accept it for transmission if it were capable of being economically transformed up and down to different pressures. The direct current dynamo is really an alternating dynamo with a commutator placed upon it. If the commutator, instead of being placed there be placed in the neighbourhood of the motor, we obtain most of the advantages both of the continuous and of the alternating current. This is one of the advantages of having two phases generated by the dynamo, because it is much easier to rectify a two phase current than a single phase current. In addition to the motors above specified, there are a large number of single phase motors which start with a powerful torque which have been invented by different electricians, but which are not yet put upon the market. There are also machines with commutators like a direct current dynamo with laminated field. These all become very efficient and useful when the frequency of alternations is sufficiently diminished.

Line Construction.

A great deal of attention has been given to the different methods by which current can be conveyed to the points of consumption, whether on our own property or at Buffalo, or even further. Naturally the pole line was first dealt with, in which the poles might be constructed of either wood or iron. This is the cheapest type of construction, and has some advantages, but we must consider the climatic conditions in the neighbourhood of Niagara Falls. We are subject there to severe thunderstorms, and troubles from lightning have already been serious in several parts of the United States in connection with electrical machinery. Snow and frost are very severe, and sleet forming upon the wires and insulators may cause a great amount of trouble. There are also at times very violent gales sweeping from over Lake Erie. All these difficulties can be counteracted to some extent, but it is nearly certain that with overhead construction occasions would arise when the continuity of operations would be interrupted, and this would be a very serious matter. The next system to be considered in order of cost would be underground cables, but I am strongly opposed to the adoption of these for any considerable length. It is true we are able to deal with their capacity so as to reduce its injurious effects, but surely the best plan of all is to abolish the capacity itself as far as possible. The most satisfactory method of proceeding is to build a subway of sufficient size to enable a person to walk along it and to carry bare copper conductors in it, but this is a matter of considerable expense. I am glad, however, to be able to inform you that the officers of the company resolved last summer that a subway such as I have described should be constructed from the power house up to the Pittsburgh Reduction Company's works, where aluminium is to be produced, a distance of 2,500ft. In accordance with their instructions, I prepared plans, which are now exhibited, and which give space enough to carry the conductors at 20,000 volts for all the power that will be developed by the present tunnel, parallel working being adopted. The subway is built of concrete, having a minimum thickness of 10in. The height inside is 5ft. 6in. Wooden beams are embedded in the concrete on both sides every 30 feet. When the concrete is set, these beams are removed, and iron castings for supporting the brackets that hold the insulators are put in their place and these are then grouted in. Iron brackets as shown in the drawings are bolted to these castings and the oil insulators placed upon them. Copper wires are shown as being supported on these insulators, but we shall probably adopt copper strip. The bottom of the subway is always on an incline, and is of curved shape to drain off any water of condensation, but it is also proposed to force air through the subway so as to keep it dry. The 2,500ft. now being completed is all drained at the power-house end by a boring into a water bearing stratum. At the bottom of the subway the concrete is formed in two steps, the lower one of which supports sleepers for a very light tramway upon which a truck can run to carry supplies, and also to carry the inspector. At first this can be moved by a hand lever, but arrangements are made for eventually driving it by electricity, the conductor being carried on the floor, between the stringers (placed on the ties or sleepers), which form a platform running along the length of the subway. On the stringers outside the rails is placed a screen separating, mechanically and electrically, the part of the subway where the conductors are from the part where the inspectors walk. This screen is formed in 10ft. lengths of wood supporting expanded metal, covered over with plaster up to a height of within 1ft. of the top, the upper part being left open in the form of a network, through which the inspector can look at the conductors and their supports. These screens are held by iron supports fixed by expanding bolts into the concrete, and can easily be removed. The top of the arch is 3ft below the surface of the ground, so that it will not be affected by frost. According to the last report, it appears that on the 21st of October 1,590ft. of this subway had been completed; the total length being put down at present is 2,500ft. Each of the iron castings has a wire attached to it which passes through the concrete, and is soldered to a copper wire running outside the subway along its whole length, and connected to a plate sunk in the water at any suitable points. At every 400ft. cross streets will be made, and at these points there is a manhole. Also at these points, on each side of the subway, four drain-pipes, 3in. in diameter, are let in, closed at their outer ends. When the subway is to be tapped for use on the side streets, or for intermediate points, wires can be laid through these points. Between Niagara Falls and Buffalo there is very little rock, but the part where the subway has now passed through has been chiefly in rock. This involved blasting out a channel larger than was required. In this case the part of the trench outside of the subway has been built up of stone. In the construction of this subway American Portland cement has been used, and a very suitable sand from the neighbourhood which contains its own gravel. The whole of this work has been done by Mr Humbert, and up to the date of my last inspection every part was thoroughly and satisfactorily done. This work is of great importance as conveying to the minds of those who intend to use our power some idea of the desire to ensure continuous working.

With regard to the electric pressure that is to be used for distant transmission, this will undoubtedly advance with experience. Some manufacturers in Europe who tendered for the work proposed to adopt 25,000 volts, which is a step in the direction of Lord Kelvin's suggestion of 80,000 volts; but we have considered that at present 20,000 volts is not likely to be exceeded by us, and we may work at a lower pressure at the commencement. When it is remembered that the Deptford machines have one terminal connected with the earth, and are working satisfactorily at 10,000 volts, and when it is noticed that, in consequence, our work would be under exactly the same conditions as regards insulation when working at 20,000 volts, it is easy to see that we are not risking anything experimental in our first work.

With regard to the size of conductors, I worked out the economical size at different current densities for the whole distance. In doing this I took the following data: I took the cost of copper

at 12½ cents per pound, and the annual charge on this cost at 5 per cent. I then computed the power loss in the line, and the amount of power which was left available for delivery. I took the value of this power at the distant end of the line as being 15dol. per horse-power. This is something more than what it costs us to produce it, but when the power available from our tunnel is nearly all consumed this quantity will have to be increased. It must also be remembered that I have not allowed for the increased size of the conductors required by the retardation of phase, which is an unknown quantity. Still, it will be seen that from these considerations we may be able to work economically at a slightly higher current density than is obtained from this investigation. From this work it appears that the most economical density to work at is 350 amperes per square inch. If this density is used, the fall in volts between Niagara Falls and the northern boundary of Buffalo is only 3½ per cent.—a matter which makes regulation extremely easy.

With regard to the efficiency of the system, it is remarkable how high the efficiency of the dynamos comes out when we are dealing with the large units of 5,000 h.p. There can be little doubt that the efficiency, electrical and mechanical of our dynamos may reach at least 98 per cent. Taking off 3½ per cent. for losses on the line, we would have 94½ per cent delivered electrically at Buffalo if no transformers were required to raise the electric pressure to the full 20,000 volts. In cases at Buffalo where the power consumed is very large, the motor can be constructed on the same principles as the dynamo; and if in this case it be ever possible to work at the full pressure without a transformer, it is obvious that the total efficiency of the system—that is, the power delivered by the motor to the shaft of the machinery divided by the power delivered by the shaft of the turbines to the dynamo—will be certainly over 90 per cent. As a matter of fact, if we were to use a higher density of current, and were to use step-up transformers at Niagara Falls and step-down transformers at the northern boundary of Buffalo, and other step-down transformers in the town of Buffalo itself, and were to use motors of small power, and consequently less efficiency—in this case the total efficiency of the plant might be reduced to 80 per cent., or even lower.

I have given these figures, not as indicating precisely the lines on which we have determined to work at Buffalo, but because the present paper is intended to embrace the subject of the general distribution of power, and I thought it desirable to lay before you certain facts in this connection in a definite form

Description of Machinery to be Used

Under this heading I shall deal chiefly with the type of dynamo which has been finally decided upon. It will suffice to say of the turbines that they are each of 5,000 h p., that they revolve at 250 revolutions per minute, and were designed by Messrs. Faesch and Piccard, of Geneva. All the principal parts of this machinery were constructed by the I. P. Morris Company, of Philadelphia, but the governors of the turbines are of Swiss manufacture, and part of the steel fittings were constructed in France.

With regard to the dynamo, the Cataract Construction Company at first invited many different manufacturers in Europe and America to submit plans. The number of these that were submitted altogether amounts to 24, some of the manufacturers having taken a great deal of trouble to submit a series of designs, in order to be able to meet different requirements. Many of these designs were extremely good; but it was determined, after estimating the increased cost of using the European designs, owing to the high tariff in America, and owing to transport, to have the machines manufactured in America. Among the designs from American manufacturers there were none which fulfilled all the requirements of the case, and eventually the Cataract Construction Company decided to get out their own designs, and to submit them to the American manufacturers for tender. I had been for some time previously engaged in working out a design which I am confident none of the manufacturers who had sent in designs could say was in any way borrowed from their ideas. We had received suggestions of an external armature with internal revolving fields, and also of external fixed fields and internal revolving armature. We naturally had a preference for a dynamo with a fixed armature, because the coils can be more securely wound, and are not subjected to the mechanical stresses induced by centrifugal force. But all the designs with revolving fields which had been submitted to us contained a weak feature. The field coils were held in by pole faces secured by bolts or keys to the poles, and this seemed an element of weakness when we considered the enormous centrifugal forces to which the machinery would be subjected. At the same time, the turbine makers had insisted upon having a certain momentum, or flywheel effect, which was not given by the revolving parts of any of the dynamos submitted to us, and it was found that if any one of these had been accepted it would have been necessary to add to the design a flywheel of large dimensions. Centrifugal force was one of the most important matters to be considered, because at 250 revolutions per minute this force assumes a considerable magnitude in the large masses with which we had to deal. Moreover, in all the designs which had been submitted, the magnetic pull between the poles and the iron of the armature assisted the centrifugal force. The principal feature of the design upon which I was working consisted in having the armature fixed, and inside the machines, with the fields revolving outside; the fields being formed of a ring of iron with the poles projecting radially inwards. One advantage is that we are able to get the full flywheel effect that was required by the turbine-makers. This requirement was *that in the revolving part* the sum of the weights in pounds of each part, multiplied by the square of its velocity in feet per second, should equal 1,100,000,000. The design also gives an extremely good mechanical construction for the revolving parts. The iron ring which forms the yoke of the fields serves as a support to hold in the pole pieces and the exciting coils, and no part is held in against centrifugal force by bolts or keys. Moreover, the magnetic pull between the fields and the armature acts in opposition to, and does not assist, the centrifugal force. The armature is fixed, and a large space is available inside it for the workmen to attend to the bearings, and to reach any part of the armature. It is obviously possible to insulate the armature coils for any electric pressure. With a large machine of this kind the space occupied by insulation has not the same importance in reducing the output of the machine as is the case with machines constructed in the past. In fact, the armature coils can be wound with the same insulating properties as a transformer, and hence the necessity for using a step up transformer can be avoided.

Starting with this general principle I first got out designs of a machine at 33 periods per second, in order that I might compare the general appearance of such a machine with those of other types. The next point was to design a machine of as low a frequency as was possible under the limiting conditions as to weight. The revolving parts of the turbine and dynamo, and the shaft connecting them, are supported by a hydraulic piston, and it was the desire of the Cataract Construction Company not to use a thrust bearing of any kind to support the weight, although there is a thrust bearing at the top of the shaft, which simply acts to retain the apparatus in a fixed position in a vertical direction. Owing to this decision, it was necessary to limit the weight of the revolving parts of the dynamo to 80,000lb. In getting out the design for this machine it was desirable to select such a form of winding as past experience led one to believe would be most efficient for parallel working, and I judge from past experience that this is best attained by having the number of coils per pole very small. The 33 period machine which is shown in the drawings has only been sketched out with a view of getting at the general dimensions of the machine. It is not suitable for our special purpose, because it is essential that, without taking the dynamo altogether to pieces, we should be able to lift up through the centre of the dynamo any parts of the turbine shaft which may require repair.

It will be seen that from the necessities of the case at Niagara Falls the dynamo which was required differed in some respects from what would be necessary in many other cases, but it is equally obvious that in any case of so large a transmission of power the conditions must be thoroughly considered beforehand, and the dynamo specially designed for the purpose. At the meeting of the board of directors of the company, in May, 1893 I was instructed, with Dr Sellers to get out plans for an alternator of the type which I have described. I am not able to lay before you now plans of the machine as it had been finally adjusted by conference between ourselves and the manufacturers. In the plan which we prepared, the frequency was 16⅔ periods per second, there being eight poles. The armature coils were so wound that they might be connected to give either 2,500, 5,000, 10,000, or 20,000 volts, and the coils were limited in number so as to give the best assurance of good parallel working. For various reasons we decided eventually to raise the frequency to 25, and to lower the volts to 2,000, without the means of connecting the coils to give a higher pressure, and instead of winding the armature on the conductors in a limited number of coils, to adopt the methods more commonly used in some of the large types of generators. But since in any future work which is done the dynamo will be required to be modified for the special purpose, a description of the machine—of which I am able to show you the drawings—is sufficiently representative of the type of machine for our purpose.

General Description of a 5,000 h.p. Alternator.

On the bed plate a vertical cylinder is bolted, with projections to support the fixed armature and the bearings of the revolving part. The armature coils are wound independently, and can be removed and changed. They are fixed in slots in the fixed armature. They are encased in an oil-tight casing, through which oil can be circulated. The field magnet is external to the armature, and has the poles pointing radially inwards. It consists preferably of forged steel supported by a spider with eight arms which may be of steel with a covering of thin sheet metal, on which cups are provided for forcing air into the interior of the machine. The pole pieces are bolted on to the steel rim. The field coils are of copper strip, two coils being wound upon each pole, with a space between them for air circulation. The exciting current is applied by rings of tempered copper on the spider, having fixed brushes rubbing on them. The hub of the spider is firmly fixed to the upper end of the shaft. The spider supports the heavy rim by 16 studs and nuts. The shaft is supported by two bearings, each of which has four radial arms, which are bolted to four corresponding projections on the cast-iron cylinder. This cast-iron cylinder is bolted to the bed-plate and adjusted thereon by wedges. Besides having on it the projections for carrying the bearings on its inner side, it has on its outer periphery a series of vertical ribs, against which the stampings, or sheets of iron forming the armature, rest. It also supports the lower end plate on which the armature is built up, and the armature is keyed to it by a single key. The armature is wound drum fashion—that is, all on the outside. This enables the coils to be wound independently and laid in their place, and also to be easily replaced in case of accident. In order to do this satisfactorily, the slots for each coil in the iron are cut, not radially, but parallel to each other. Each coil is encased in insulating material, which forms a tube through

which oil may flow, as in a transformer, but may be forced, in which case its circulation is maintained by a pump. Round the base of the machine there are two oil pipes, one being the inlet and the other outlet. The inlet pipe is connected with a reservoir of oil in the power house. The outlet pipe leads by another pipe to cooling arrangements in running water, from which the oil is pumped to the reservoir. From the inlet pipe 16 brass tubes are led to the junction boxes at the bottom of the 16 coils; the 16 other brass tubes are led from the junction boxes at the top of the coils through the interior of the fixed armature and bent over the foundation plate, and so connected to the outlet pipe which surrounds the bed plate. The bed plate is a single iron casting, and in order to enable it to be transported over the railways it was necessary to limit its diameter as shown in a supplementary drawing, which shows the improved oiling arrangements, which were worked out by my chief draughtsman at Niagara Falls, Mr. Baumann. The armature is built up of thin sheet iron, with ventilating spaces, as shown on the drawing. The bolts which hold the armature together are eight in number, to be made of nickel steel, a metal which has the great advantage of being non-magnetic, and of very high electrical resistance and great mechanical strength. The amount of nickel is 25 per cent. There are 16 armature coils, eight being of one kind, called "short" coils, and eight of another kind called "long" coils, the length of wire on each coil being the same. The short coils are bent over at the end plate, and the long coils are wound in one plane and enclose the short coils. I find that if we are to have a very stiff field, with first-class quality of iron in the fields, each coil would consist of 72 turns of pure copper wire, No 0 of the Brown and Sharpe gauge, which gives a very low density of current and reduces the heating. In fact, it has been my view that in designing the machines for so great and permanent a work every effort should be made to reduce the rise in temperature, even to far below what has ever been done in the past. The unequal expansions and contractions of materials in a machine of this kind are very injurious to its permanence, and affect the insulating material seriously. The layers of wire in the coils are separated by mica. Each coil when wound has strips of insulating material laid spirally round it, so that oil may circulate freely in the intervals, and the whole is encased in a casing of strong insulating material. The material which I prefer for this purpose is certainly woodite, an eighth of an inch of which will not break down with 30,000 volts, and which is not acted upon by oil even at high temperatures. I have a record of tests with oil which are conclusive on this point. It is quite the best material I have seen for the purpose, though costly, and, being a secret process, it may be difficult to ensure uniformity. The frames of the bearings are of cast iron, with four radial arms, which rest upon four projections cast on the vertical cylinder, and are bolted to them. By this means, when the field magnet with the shaft have been lifted out of place, the bearings can be twisted through an angle of 45deg. in a horizontal plane and then raised out of place, leaving a space 5ft. in diameter through which portions of the turbine shaft can be raised for repair. The bearings are oiled at the centre by oil forced under pressure through a pipe. The oil is then distributed over the bearings by spiral grooves. A spiral groove is also cut in the hub of the frame, with a pipe at each end to admit of water circulation to cool the bushing. At two opposite sides of each bearing the bushing is made thin, and a rod of bismuth is soldered thereto; so that if the bushing is heated a thermo-electric current shall be created which, by means of a relay, can ring a bell in the power house. When this occurs, water can be immediately admitted to cool the bearings, and the attention of the workmen is drawn to the necessity of an examination. One of the parts which required most consideration was the material of which the spider supporting the field magnets should be constructed. The best plan is to make it of steel, for the sake of lightness, and to cover it with a copper covering, which might, I think, be spun; or, perhaps better, electro-deposited nickel might be used. Between the pole-pieces the space is filled up with a screen or plate of metal so as to direct the air ventilation only upon the parts which most require cooling. The methods finally selected for oil circulation are shown in a separate drawing.

(To be concluded.)

Institution Meeting, November 23.

MR. W. H. PREECE, F.R.S., President, in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Members.—Thomas Octavius Callender, 101, Leadenhall street, London, E.C.; Ormond Higman, Ottawa, Ontario, Canada; Thomas Preece, 102, Preston street, St. Andrews Villas, Bradford.

Associates.—Arthur Ellis, Cambridge Electric Supply Company, Limited; John Gordon, 51, Main-street, Rutherglen, Glasgow; R. C. Holness, 3, St. Martin's road, Stockwell, S.W.; Frederick W. E. Jones, Midland Electric Light and Power Company, Leamington Spa.

Students.—Ernest Arthur Bayles, Barwood, Caterham Valley; Hugh Capper Crawhall, Faraday House, Charing Cross road, W.C.; William Alan Fraser, 121, Adelaide road, N.W.; Herbert William Miller, Faraday House, Charing Cross road, W.C.; Drogo Montagu, 2, Redburn street, Tedworth square, Chelsea, S.W.; Evelyn Henry Terrell, 104, Philbeach-gardens, Earl's Court, W.

The reading and signing of the minutes and the ordinary formal business having been carried out, the **President** rose, and in a few brief and touching words referred to the loss which the Institution had sustained by the death of Mr A. Reckenzaun; and on the proposition of **Mr. G. Kapp**, seconded by **Mr Mordey**, it was resolved that a vote of condolence be officially sent by the Secretary to Mrs. Reckenzaun.

Prof. A. Fleming then commenced the discussion on Prof. Forbes's paper, and congratulated the Institution upon such a valuable contribution to its *Journal*. It was not often that engineers took the public into their confidence and laid open the plans proposed during the progress of a work, or, as it were, opened their minds, showing the inner reasons, and inviting criticism. He would confine his remarks to one or two points. The difficulties of transmission over long lines were very real, not of the fashion of professors' difficulties, and had to be overcome. It must not be assumed that the effects of capacity could be neglected. No doubt the choice of a particular type of line had been dictated by a desire to avoid those difficulties as much as possible, and to reduce the capacity effects. It was absolutely necessary to avoid the pressure effects which with alternate current distribution took place when lines were suddenly connected or disconnected from the machines. It was useless to talk of failure of insulation in those cases for the pressure effect was often such as no insulation whatever could stand, and therefore the pressure effect itself must be minimised or eliminated. Prof Fleming mentioned that the deleterious effect had been got rid of at Deptford by the engineer, Mr. D'Alton, after discussion with him. This was by the use of a transformer having in its secondary circuit a great resistance, which could be gradually thrown on or off. The apparatus required three switches, but in effect, by means of this transformer, a very great impedance could be obtained, say on making contact with the concentric mains. This impedance was gradually diminished, and so no harmful effects were found in the mains. The operations at breaking the main circuit were the reverse of those at the making. The speaker pointed out that the capacity of these cables was about ⅓rd of a microfarad per mile, and that as the damaging effect varied as the square of the current it could never be slighted, and was, in fact, often disastrous. These effects were increased by increasing the frequency, hence one reason for reducing the frequency as low as possible. Prof. Fleming then gave allegiance to the Continental plan of using an artificial resistance on putting machines in parallel, specially referring to the resistance at Tivoli, where some 300 horse power could be absorbed, which was about the output of one of the machines in use. He was sorry the system was not adopted in England. He also pointed out that there was a good opening for the invention of a main fuse for alternate current circuits, which, when the current passed a certain point, should put in great impedance, or, when necessary, take out impedance without ever absolutely breaking the circuit. He would like to know in Prof. Forbes' reply the distance between the conductors, because he feared the effect of arcing with a pressure of 20,000 volts, if they were too close together.

Mr. Mordey said that the practical experience of some differed from that of others; therefore it was of great value to obtain united experiences, so as to have something of settled character in practice. One great value in Prof. Forbes's paper was that it not only gave experience—it gave reasons. Probably they were all agreed as to the use of alternate currents for large power transmissions. He agreed generally with the scheme as put forward in the paper, but differed upon points of detail. He denied, for example, that parallel working was assisted by lowering the frequency. If there was no difficulty found in parallel working with frequencies of 100, why want to work at a lower? He ventured to ask if the reason put forward was correct, why Ganz used a periodicity of 42—viz., as that was the lowest which worked in parallel without flickering of the arc lamps. He asked this because, in a paper of his own, he quoted a published letter of Zipernowsky, which was contradicted in a subsequent communication from the same source. He thought it had happened that certain makers used a periodicity of 42 before parallel working was looking upon as important, then experimented and altered to use this periodicity even with parallel working. With regard to the artificial loading mentioned by Prof. Forbes, and approved by Prof. Fleming, he looked upon that as an obsolete system. It was used by Edison with the old "Jumbo" machines at Holborn, and was still used at Milan. It was utterly unnecessary, and naturally he preferred the method described in a paper of his as devised by himself and Mr. Raworth, which consisted in playing upon the field excitation and the steam regulation, and by which there was no difficulty with pressure or sparking. Even with machines with a big drop in the curve, no artificial load was required. He thought the system continued to be used on the Continent because it had become stereotyped, and was put in as a matter of course. He pointed out that the low frequency was not required for transformers.

Mr. G. Kapp thought that the Institution should be congratulated on the fact that one of its own members had been selected for this paper. Prof. Forbes in one portion of the paper discussed the merits of the number of phases—whether single, two phase, or three phase. When in America in the summer, the speaker conversed with Prof. Thomson about this question. The latter tried to convince him that three phases would require less copper than two, but he could not see it. When he returned from the States he investigated the matter, and then saw daylight on the subject.

United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers have their own copies bound for 2s. 6d., or covers for binding be obtained, price 2s.*

BOARD OF TRADE AND ELECTRIC TRACTION.

The Right Hon. A. J. Mundella, in his speech at the Institution dinner, referred to the progress of electric traction in this country. He explained that the Electric Powers (Protective Clauses) Joint Committee, in their report, suggested the framing of regulations by the Board of Trade in this matter, and that draft regulations had accordingly been prepared. These draft regulations are given elsewhere. It was stated by the President of the Board of Trade that the regulations would come before the Council of the Institution for an opinion before he would finally sanction them. We gather from this that the Board of Trade is desirous of obtaining opinions as to the perfectness of these draft rules, and those interested in the matter should therefore carefully examine them and communicate with the authorities. It must be remembered by those interested in tramways that if these rules are left uncriticised and are adopted, to change them will be difficult. The Board of Trade may then well listen to opposing interests and say, When the draft regulations were made public, no objection was raised: why wait till they are adopted? The criticisms to be of value must be before final adoption, and no doubt there will be little hesitancy in expressing criticisms. We are of opinion that in several particulars the rules will be found unnecessarily stringent, and if our supposition is correct, the Institution might, with great benefit to the industry and with credit to itself, set aside one or two evenings of the session for an open discussion of the whole subject. A discussion of this kind, if properly organised, would greatly aid the Council in giving an opinion upon the regulations. The electric traction people only want to live, and do not desire the extinction of telegraphs or telephones, or to conduct their lines so as to eat up their neighbours' pipes. We make this suggestion from an experience of years ago, when a learned society set aside a whole session for the discussion of a particular book. The benefit accruing from that action was acknowledged to be far and away above what obtained from the reading of papers. The Council might easily arrange for certain paragraphs to be discussed on a particular evening and obtain a number of speakers to discuss from opposite points of view. The Council at the end of the discussion would have all the facts and opinions before them, and would act as a judge in summing-up. Such summing-up would be their opinion to be delivered to the Board of Trade.

HALF TRUTHS.

If an inventive genius could patent some method of counteracting the effects of incorrect information, it might be a blessing to the world. Electric lighting has had a tough fight to establish itself as the coming illuminant. Its opponents have been many, its detractors not a few, yet gradually it has pushed its way. Had its properties not been good it would long ago have been snuffed out. Still, we must not for a moment imagine that its calumniators are dead or are withdrawing from the conflict.
